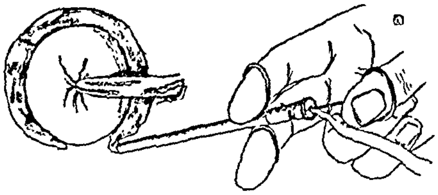
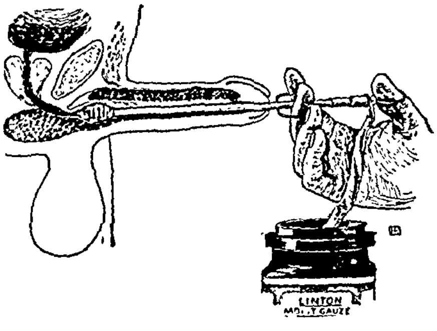
The instrument consists of a body tube twelve inches long (I am describing size 3), one-fifth of an inch outside diameter, having two ring handles attached to its upper end, for the index and middle finger, and having within it an inner retarding tube provided with a flange above and so cut out below as to form three spurs, which project slightly into the lumen of the lower end of the tube, permitting forward movement but preventing any backward movement of the gauze when the packer is moved back to obtain a fresh hold on the gauze. A cap screws on to the upper end of the body tube to hold the retarding tube in place, having an opening in its top equal in size to the lumen of the retarding tube.



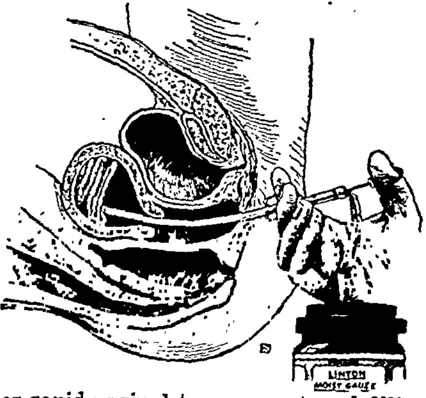
The packer is a steel rod having three outwardly directed spurs at its lower end, for engaging the meshes of the gauze and forcing it down toward the delivery end of the body tube, and at its upper end a ring handle for the thumb and a guard to prevent its entering too far and doing injury to the tissues at the lower end. The instruments are made in four sizes, Nos. 1, 2, 3 and 4.



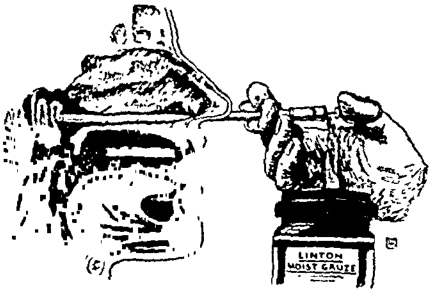
No. 1.—For nasal use in children or adults with deflections of septum or obstructive hypertrophy. It is six inches long, three-twentieths of an inch outside and takes one-half inch gauze.

No. 2.—For general nasal use. The vast majority of nasal tamponments may be made with this instrument. It is seven and one-half inches long, one-fifth of an inch outside, carries one and one-half inch gauze. It is the same diameter as No. 3 instrument.

No. 3.—For general and military surgery and gynecology. It is twelve inches long, one-fifth of an inch outside diameter and carries one and one-half inch gauze.



No. 4.—For rapid vaginal tamponment, and filling the uterus post-partum. It is eight and one-half inches long, two-fifths of an inch outside and carries a strip of gauze four to six inches wide.



THE FOLLOWING CLAIMS ARE MADE FOR THE GAUZE CARRIER.

It will rapidly, and in many cases painlessly, pack gauze into cavities, wounds, fistulæ or sinuses. The gauze, not coming in contact with the superficial portions or walls of the cavity until it reaches the desired point, is introduced aseptically. It can be properly sterilized. Being to some extent flexible it can be bent to the curvature of tortuous wounds. By its aid the uterine cavities can be more quickly, firmly, painlessly and aseptically packed with gauze than by any other method now in use. The nasal cavities and the nasopharynx can be quickly and firmly packed with gauze to check or prevent hemorrhage or to take up secretions. Punctured wounds or gunshot wounds can be promptly drained. Re-packing of any deep wounds is less painful than by any other method. Only one strip of gauze need be used for any cavity. Removal of the gauze is therefore easy. Moreover only one introduction of the instrument is necessary at one dressing. Re-infection is therefore less likely. The packing or tampon is introduced from the distal side toward the proximal side of the wound or cavity. The gauze is transferred directly from container to cavity and is not touched by human hands. For the nares or small cavities use gauze one-half inch wide; for general surgical purposes and the uterus one and one-half inches wide. For vagina tamponment use gauze four inches wide. The length of stroke of the packer should be about two or two and one-half inches. Short strokes will pack lightly, longer strokes firmly, to some extent independently of the width of strip of gauze used.

I have had these instruments made by Johnson & Johnson, of New Brunswick, N. J.

Pentosuria.—Bial describes two cases of pentosuria in the *Zeitschr. Klin Med.*, xxxix, 5 and 6, emphasizing the points that differentiate it from mellituria. Urine containing pentose reduces powerfully, does not ferment and has no polarizing properties, but it is chiefly distinguished by the positive results of the orcin and phenyl-hydrazin tests. Glycuronic acid gives the same reactions, but can be differentiated with brominphenylhydrazin, with which it forms a combination not readily soluble in water and strongly levorotatory, differing in this respect from pentose.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

SATURDAY, SEPTEMBER 29, 1900.

THE PASSING OF THREE EX-PRESIDENTS OF THE AMERICAN MEDICAL ASSOCIATION.

During the past week three ex-Presidents of the American Medical Association have died, Drs. Hunter McGuire, Lewis A. Sayre, surgeons of worldwide reputation and foremost men in their profession, and Dr. Alfred Stillé, renowned as a physician and as a teacher.

Dr. Sayre has been called the father of orthopedics, a surgical specialty that is indebted to him more perhaps than to any other one man. His work in this department was notable from the very beginning of his practice, and he early obtained an international fame both as an originator of new methods and as a successful operator. He was eminent, however, not only as a surgeon, but also as a sanitarian, in which capacity he made one of the best health officers New York has had. The honors he received were numerous, but of none of them was he more proud than that of the Presidency of the American Medical Association, which position he held at the session of 1880.

Dr. Hunter McGuire was not only eminent as a surgeon, but was also the idol of his section of the country from his record in the Civil War, in which he was the most intimate friend and associate of "Stonewall" Jackson. He was a man of strong individuality, and has left his mark on the profession that will not soon be obliterated.

Dr. Stillé, the last of the three, the notice of whose death comes to us as we go to press, has been for many years conspicuous among the men who have made Philadelphia a center for medical progress and instruction. Like Dr. Sayre, his connection with the Association dates from its beginning; he was active in its organization and was one of its first secretaries.

It is a strange, and an almost startling coincidence, that three from the little company of ex-Presidents of the American Medical Association should die within a space of six days; one on the 19th, one on the 21st and another on the 24th. They were all well advanced in years, the youngest being Hunter McGuire, sixty-five; Sayre was eighty, and Stillé eighty-seven.

The passing of these leaves but eleven who have acted as President of the Association. The following are their names, the years of their presidency and their present ages:

N. S. Davis, 1864-65, age 83; Elisha H. Gregory, 1887, age 76; Edward Mott Moore, 1890, age 86; Henry O. Marcy, 1892, age 63; James F. Hibberd, 1894, age 84; Donald Maclean, 1895, age 61; Beverly R. Cole, 1896, age 71; Nicholas Senn, 1897, age 56; George M. Sternberg, 1898, age 62; Joseph M. Mathews, 1899, age 53, and W. W. Keen, 1900, age 63.

LAY INFLUENCES IN MEDICAL AFFAIRS.

In the process of evolution of the medical college and hospital, lay influences have become gradually more and more dominant, sometimes to the advantage of the institutions in question, but more often to their detriment. The belief is entirely too common that physicians are poor business men and inefficient executives and administrators; but such an opinion must be based on misconception, as it will not be contended that physicians are, in general, lacking in judgment and powers of reasoning, although it must be admitted that they are too often indifferent to their own material welfare, and if they do not collect their accounts with the same promptitude and success as merchants and lawyers, for instance, it is partly because they do not look on the practice of medicine as a business in the accepted sense of that term. While, then, strictly speaking, the medical man may not be able to devote himself to matters of finance and business with the same force as his lay colleague, he must yet be recognized as an authority at least on medical matters, whether in the direction of education or of hospital organization and management. The plan, therefore, seems a wise one, to retain on boards of trustees of medical colleges and hospitals several physicians, whose counsel will prove most serviceable.

In illustration of the evil effects that may arise out of the opposite course, the experiences of the National Hospital for the Paralyzed and Epileptic, in London, may be cited.[1] This institution, whose medical and surgical staff includes the names of some of the most distinguished men in the world, has no medical representative on its board of managers, and a request for such representation, made as an outcome of certain differences, such as are almost bound to arise between a medical body, with its ethical standards, and a lay board, with its conceptions of business methods and discipline, has been denied, with the explanation that this would endanger the independence of the board and might lead to a subordination of the philanthropic aspect of the hospital work to the merely scientific and investigating. The explanation would seem to be sufficient to justify insistence on the request of the medical staff. It appears that the management of the hospital has been largely delegated to a secretary and general director, and the medical staff, as a result, has found the administration of the hospital becoming more and more unsatisfactory. Already, as one of the secondary evil results of this unfortunate state of affairs, the usual grant from the Metropolitan Hospitals Sunday Fund is to be withheld until the differences between the two bodies are adjusted.

---

[1] The Journal, p. 635.

We have here an instance of lack of tact, if not of judgment, discernible even at this distance, wholly apart from any actual defects of management. The medical staff of every hospital and the teaching staff of every medical college are not less interested in their welfare and success than lay boards of managers, and they surely contribute not the least thereto, and this fact should receive practical recognition by the election to such boards of one or more medical men of the highest character who can be trusted to serve with distinction and usefulness in places that can not be filled by any other than physicians.

THE BACTERIOLOGY OF SCARLET FEVER.

Despite the obviously infectious character of scarlet fever, and its all but demonstrated dependence on a specific etiologic factor, the most industrious investigation has as yet failed to isolate a micro-organism that is universally accepted as the causative agent. Different observers in the past have found micrococci, and especially streptococci, in the blood, the scales, the throat, and in secondary lesions, but it has not yet been possible to establish the specific character of any one of the earlier described forms. They have, on the contrary, been variously thought to be responsible for the primary disorder, for the complications, and also to be accidental. In fact, streptococci have been found in the buccal secretions of healthy individuals.

Among those who have more recently devoted serious consideration to this subject and have given time and energy to its elucidation, is Medical Inspector Class of the Chicago Department of Health, who more than a year ago described a diplococcus as the cause of scarlet fever, and whose original contention has been since sustained in several communications by himself and by others. His paper in the present issue gives the latest facts that he has developed, and especially reviews one of the most recent European contributions on this subject, which, as is too customary with foreign authors, slights American researches, and only barely alludes to his earlier observations. Dr. Class reviews the whole subject and to avoid injustice, quotes the German authors verbatim to show in their own words the agreement of the form they have found with his diplococcus scarlatinæ.

It is not always an easy matter to determine the identity or the non-identity of the several cocci that have been put forward in this connection, but, in any event, Dr. Class deserves recognition for his observations, of which those of Baginsky and Sommerfeld may prove to be but confirmatory and deserving of attention because of the conditions under which they were made and the constancy of the results obtained. Class, however, has gone much farther than the German observers, inasmuch as he has developed in white swine, by intravenous injection of virulent cultures of his diplococci, a disease comparable with scarlet fever in human beings. He has also found that the blood from convalescents from scarlet fever is capable of inhibiting the growth of the diplococci on glucose-agar, while the blood from an indifferent source manifests no such activity. The blood from convalescents further exhibits some protective influence when injected into animals subsequently inoculated with the diplococci. It would seem that he has fairly shown that the form described by him meets the requirements laid down by Koch for a specific germ, and, unless his findings can be overthrown, should be accepted as the cause of scarlatina.

Baginsky and Sommerfeld use a certain commendable caution in proclaiming their findings and admit that they may be only a confirmation of an older discovery, but they would have done still better had they given due credit to observations more conclusive than their own, of which they certainly were not totally ignorant.

THE "PROFITESS" OF CHRISTIAN SCIENCE.

The miracle-working "she" of the present day, the "profitess" of "Christian Science," has made an exhibition of herself at a local fair at Concord, N. H., sharing the attention of the public with a high diver. This is supposed to put at rest the suspicions ventured by some that "mortal mind" had got the best of her to the extent that decomposition had set in, as it has with so many of her believers. This fact was sent, with details of her procession around the race course escorted by the marshals of the fair, by special telegram, to the *Chicago Times-Herald* for the satisfaction of her western devotees. The alleged reason of the "profitess'" emergence was her human but unsanctified interest in seeing the diver jump from a height of eighty feet into five feet of water, with the chance of breaking his neck.

THE NOTIFICATION OF TUBERCULOSIS.

The Supreme Court of Michigan has reversed the decision in the lower court in the Shurly case holding that the statute did not include consumption in the contagious diseases requiring compulsory report. According to press reports, the grounds for reversal are that it was beyond the power of the court to decide in the case of this particular statute what diseases are and what are not dangerous and communicable. The court holds that there is no danger line of which courts can take judicial notice, and that this was a question for the jury to decide. A new trial was therefore ordered. What will be the outcome of the future legal proceedings before a jury in this case is, of course, uncertain, but in any event it may be questioned whether the public is yet ready to have tuberculosis put on the list of notifiable diseases; at least this is the opinion of some of the most competent to pass judgment on the subject. There are, moreover, practical difficulties in the way, and unless the whole population is to undergo some sort of tuberculin test, as is done with cattle—assuming this to be reliable and safe—it does not appear quite clear how it is to be thoroughly done. In many of its less manifest forms tuberculosis is probably as dangerous by contagion as are some of the more developed types, and it is doubtful if these will be generally reported. It may be said that it is well to use precautions imperfectly if we can do no better, but there still remains in this particular case the question whether the classing of tuberculosis among the malignantly contagious diseases, like smallpox, diphtheria, scarlet fever, etc., as enumerated in the statute, is either expedient or correct. As regards either there is still some difference of opinion.

MUSICAL TALENT AND DEGENERACY.

In an article in the *American Journal of Insanity*, on "Degeneracy in the Army," noticed elsewhere in The Journal,[1] Dr. Charles E. Woodruff makes mention of the interesting fact that the musicians in the army are in some respects different from the average soldier, that they present a larger proportion of stigmata and require a different system of discipline. These army musicians are, it is understood, generally enlisted as such, but they may be taken from the ranks if they are known to manifest especial musical ability. The observation is an interesting one, as it seems to show that talent in this particular line, at least in the class of enlisted musicians, is associated with a certain degree of defect. How much the possibility that in the recruiting of musicians there may be a laxity of inspection, as compared with that of other enlisted men, has to do with this fact Dr. Woodruff does not even suggest, but it naturally occurs to one as at least a possibility. It is hardly likely, however, that even in this case the laxity would be so great as to permit the enlistment of a regular class of degenerate musicians as compared with others of the same occupation. The natural inference from the fact is that musical talent and degeneracy to some extent are associated. This accords with the view already editorially expressed in The Journal, that music has certain degenerative tendencies that are worthy of consideration by the profession.[2] It is certainly possible that a more or less exclusive devotion to this sensuous and emotional art, as a pursuit, may be associated with an original defect, as well as develop one where it did not previously exist.

THE ROSE SPOTS OF TYPHOID FEVER.

The rose spots form an important diagnostic feature in typhoid fever. The cause of the cutaneous changes that present themselves as rose spots remained unexplained until a year ago, when Neufeld and Curschmann succeeded in cultivating typhoid bacilli from the blood in the spots, thus demonstrating that the roseola depends on the lodgment of the bacilli in the skin. But Neufeld did not succeed in demonstrating bacilli in sections of roseolous areas, and consequently a clear idea of the exact relations of the bacilli to the lesions in the skin could not be formed. E. Fraenkel,[3] who was one of the first to show that the typhoid bacilli multiply rapidly after death and that the masses of bacilli found in properly stained sections of typhoid organs are largely of post-mortem origin, succeeded readily in finding bacilli in the rose spots after preservation of the excised pieces in bouillon at 37 C. for eighteen hours. Now, bacillary masses encountered either in organs some time after death or in tissues preserved after excision indicate the localization of the bacilli during life, because colonies or groups develop only in those places that harbored single bacilli before death or before excision. Fraenkel examined in this manner spots from four patients, and the results harmonize well in all essentials. In three of the cases cultures from the blood of rose spots gave colonies of typhoid bacilli. The bacilli lodge in the papillary body of the skin and preferably in the lymphatic vessels. Judging from the small number of masses found in sections from the pieces, subjected to incubation as described, it may be concluded that but few bacilli are required to produce the cutaneous eruptions of typhoid. The efflorescences are not merely hyperemic areas, but areas of genuine inflammation with cellular proliferation, especially of the fixed connective-tissue cells. In some areas coagulative necrosis also takes place. Hence, the distinct swelling and elevation of the rose spot. From the histologic structure of the rose spot it also becomes evident that the lesion has not subsided wholly on the disappearance of the redness. And Curschmann has pointed out that in some cases brownish or yellowish spots with a little desquamation may appear in place of the rose spot. In children and young adults he occasionally observed that small vesicles with turbid contents, which rapidly dried up, developed in the epidermis of rose spots. It may be concluded, then, that the rose spots of typhoid fever are inflammatory foci resulting from the deposition of typhoid bacilli in the lymph-vessels of the skin. Whether bacilli may reach the free surface of the skin through these lesions has not been demonstrated, but it does not seem unlikely that this may occur, and the possibility of dissemination of bacilli from the skin should not be lost sight of.

Medical News.

CALIFORNIA.

Dr. James M. Shannon, Oakland, has returned from Europe.

Dr. Millard G. Hinkle, Stockton, has moved to Seattle, Wash.

Dr. Samuel H. Buteau, Oakland, has returned from a five-months trip to Europe and Asia.

Dr. J. Underwood Hall, Jr., president of the San Jose Board of Health, has been granted leave of absence for a year to study municipal hygiene in Europe.

The health report of San Jose for August shows that no contagious diseases were reported during the month. There were 27 births and 17 deaths reported—a death-rate of 8.16 per thousand. Consumption caused 4 deaths and heart disease 3.

The health officer of Oakland, Dr. James H. Todd, in his annual report recommends, and the board of health has under serious consideration, the adoption of rules whereby consumption shall be placed on the list of contagious diseases and local quarantine established against it.

COLORADO.

Dr. Russell, who has been practicing in Louisville, has located in Colorado Springs.

Drs. Charles E. and Clara S. Bryant, Pinon, Montrose County, have moved to Denver.

The Hebrew Home for Consumptives, Denver, opened a year ago, is to have a new wing, to cost about $30,000, which has already been raised by voluntary contributions. The B'nai B'rith provides for the support of this institution.

---

[1] Abstract 50, p. 846.

[2] The Hygiene of Music; Editorials, The Journal, xxxi, 189, 734.

[3] Ztft. f. Hyg. u. Infektionskr., 1900, xxiv, 482-496.

THE MEDICAL DEPARTMENT of the University of Denver opened its twentieth annual session September 11. Chancellor William H. Buchtel made the opening address. The laboratories have been newly equipped and an endowment fund for their maintenance has been started.

CONNECTICUT.

DR. VICTOR S. MERRITT, Hartford, has purchased the practice of Dr. William A. Jackson, Haydenville, and will locate there.

DR. JOHN E. MARTIN was appointed attending physician to the New Britain General Hospital, September 10. The board also appropriated $100 for surgical instruments.

DR. MOSES C. WHITE, who for the past twenty-five years has been at the head of the work in pathology at Yale University medical department, will retire from active work and will be continued as professor emeritus. The chair in pathology will be filled by Dr. Charles J. Bartlett, who has been assistant professor for the past five years. The chair of obstetrics and gynecology, made vacant by the death of Dr. George Campbell, will be filled by Dr. Otto G. Ramsay, of the Johns Hopkins University.

ILLINOIS.

DR. HARRY D. BROWNING, Little York, has sold his practice and moved to Oskaloosa, Ia.

DR. JAMES M. THORNTON has moved from Powellton back to his old home, Fort Madison, Ia.

DR. WILLIAM B. MADDOX, Augusta, was married to Miss Ida King, of Keokuk, September 13.

DR. STANLEY BURR DICKENSON, Austin, was married to Miss Nellie Cummings Shurtleff, September 26.

DR. S. P. HART, Auburn, has moved to Waverly and has entered into partnership there with Dr. J. H. Barto.

DR. WILLIAM S. CRAWFORD, Galena, has been elected county physician of Jo Daviess County at a salary of $300 a year.

DR. CHARLES B. FRY, Mattoon, has been appointed chief surgeon of the Peoria division of the Illinois Central Railroad.

DR. NELSON A. WRIGHT, Ramsey, has purchased the Manito property and practice of Dr. Thomas C. Murphy, and has moved to Manito.

THE SUPERVISORS of Winnebago County have appropriated $500 to the city hospital and the same amount to St. Anthony's Hospital, Rockford.

THE CORNER-STONE of the new Deaconness Hospital, Bloomington, was laid September 10. The building is to be in the shape of a Greek cross, two stories in height, and will contain forty rooms, including an isolation ward.

THE ATTORNEY-GENERAL is about to bring suit against the Metropolitan Medical College, formerly the Independent Medical College, Chicago. The charge is made that the institution issues diplomas without requiring a preliminary course of study.

Chicago.

DR. ALBERT H. HOY and family have returned after a summer spent in Europe.

DR. FREDERICK M. RITTENHOUSE was married to Miss Mary L. Wood, Cairo, September 25.

DR. AND MRS. JOSEPH MATTESON have returned from a three months' trip to the Black Hills.

MEDICAL INSPECTION of the public schools began September 17 by a force of fifty inspectors.

THE CHICAGO MEDICAL SOCIETY is about to publish an official medical directory of Cook County. The first meeting of the season will take place October 3.

THE PHYSICIANS' CLUB met September 24, Prof. Albion W. Small of the University of Chicago in the chair, and discussed "The Requirements for Admission to the Medical School."

THE MEDICAL STAFF of the Norwegian (Tabitha) Hospital has founded a library for the use of patients and attendants. It consists of 500 volumes, and represents an outlay of about $1000.

THE SOUTH CHICAGO HOSPITAL will soon be opened. A house containing thirteen rooms has been purchased, and is now being renovated and prepared for patients. The officers of the Hospital Association are: Dr. Charles F. Swan, president; Dr. Albert W. McLaughlin, vice-president, and James J. Larkin, treasurer.

DR. G. FRANK LYDSTON is about to issue a new book, from the Riverton Press, Chicago, under the title of "Panama and the Sierras, a Doctor's Wander Days.". It will contain observations and character sketches gathered during several trips to the Isthmus of Panama, the west coast of Central America and Mexico, and the Sierra Nevada, and will be profusely illustrated.

THE NORTHWESTERN UNIVERSITY MEDICAL SCHOOL will open for its fall session October 2. Dr. Joseph Zeisler will deliver the opening address on "Specialties and Specialists." With the completion of the new Wesley Hospital, now well under construction, the college will have more than 700 hospital beds for clinical instruction. Prof. Weller Van Hook, chief surgeon of Wesley Hospital, has reorganized the course of didactic surgery. A new amphitheater, with a seating capacity of 300, is to be constructed at Mercy Hospital for Prof. J. B. Murphy's clinic. Dr. William E. Schroeder has been made associate professor of surgery and, together with Prof. S. C. Plummer, will be associated with Professor Van Hook in Wesley Hospital.

HEALTH DEPARTMENT.

The deaths reported for the week ended September 22, 440, exceeded those in the corresponding week of 1899 by 25, the respective death-rates per thousand being 13.53 and 13.45. Of males, 364, and of females 176 died. There were 94 deaths under 1 year of age; 59 between 1 and 5 years, and 76 over 60 years. The principal causes of death were: Acute intestinal diseases, 77; consumption, 54; heart diseases, 41; nervous diseases, 36; violence, 36; pneumonia, 22; cancer, 17; Bright's disease, 15; typhoid fever, 7; suicide, 5. During the week, 41 examinations of food and 28 for suspected diseases were made in the laboratory. Of contagious diseases, 87 cases were reported, of which 54 were diphtheria. At the stockyards, 45,940 pounds of meat were condemned. Of the 297 specimens of cream and milk analyzed, 14 per cent. were below grade.

INDIANA.

DR. REID A. WHITE, Lafayette, will locate in Helena, Mont.

DR. GEORGE H. GRANT, Richmond, is very ill with typhoid fever.

DR. GEORGE M. YOUNG, Evansville, surgeon for the southern lines of the Illinois Central Railroad, has been made local surgeon of the northern lines also.

THE MEDICAL COLLEGE of Indiana has set aside $1500 to maintain fifteen beds at St. Vincent's hospital for use in bedside instruction to senior and junior students.

DIPHTHERIA is running a severe course at South Bend. In August there were 130 cases and 13 deaths, and up to September 13 there had been 77 cases and 7 deaths for the month. The health authorities are now "trying to maintain the strictest quarantine."

DR. J. MILTON RHODES, Indianapolis, who was fined for assault and battery by a justice of the peace on account of a collision which occurred while he was driving to see a patient, has been held by Judge Alford, of the criminal court, not liable for the injuries inflicted.

IOWA.

DR. MARY L. GEISER, Keokuk, has returned to Fort Madison.

DR. EDWIN C. BLISS, Grinnell, has moved to Radcliffe, Hardin county.

DR. JOHN T. HENDERSHOTT, Monroe, has been obliged by ill-health to move to Southern Colorado.

DR. H. C. HOMER, Waterloo, has moved to What Cheer, where he will be associated in practice with Dr. John A. Ri

TYPHOID FEVER is epidemic [illegible] sta[illegible] [illegible]m, Indepen[illegible] Thus far there have been [illegible] [illegible]aths. A water-tank is said to L[illegible]

KANSAS.

Dr. C. E. Munn, Topeka, has been appointed city bacteriologist.

Dr. Percy L. Germane, who has been residing in Grandin, Mo., has returned to Holton.

Dr. Benjamin E. Jones, Buffalo, has been appointed head physician of the Modern Woodmen of America for Kansas and Oklahoma, and has moved to Kansas City, Kan.

A "doctor," of Randolph, recently convicted of practicing medicine under a diploma from the Independent Medical College of Chicago, has been arrested at Hays City and brought to Topeka by the United States Marshal, on the charge of negotiating through the mails for the sale of some bogus medical diplomas. He will be arraigned before the United States Commissioner.

MARYLAND.

The Cecil county board of health advises the establishment of a county hospital at Elkton.

The report of Dr. J. Clement Clark, superintendent, shows that there are 229 male and 63 female patients in the State Hospital for the Insane, at Sykesville. Many applications are being received for the admission of private patients, and the superintendent thinks it might be advantageous to the state to receive them until the hospital is filled.

Baltimore.

Dr. Frederick Dobyns will spend October in Paris.

Dr. Edward J. Bernstein has returned from Europe.

Dr. Alexander D. McConachie has returned from a visit to Canada.

Drs. Francis T. and L. Wardlaw Miles have returned from Europe.

Drs. Thomas S. Cullen and Francis J. Kirby have returned from Paris.

Dr. B. Merrill Hopkinson has returned to the city after a summer's sojourn at Prout's Neck, Me.

Dr. R. T. Fleming has resigned his position as assistant resident physician at the City Hospital, and Dr. Owen will succeed him.

It is proposed that the health department undertake the destruction of the mosquitoes and thereby the eradication of malaria, which is quite prevalent at this season of the year. By pouring a small quantity of common kerosene oil in each of the 70,000 privy vaults and in all stagnant pools, it is believed that these pests can be eradicated. Mosquitoes are the bane of our citizens for five or six months annually.

The health department has made arrangements with the authorities in charge of Catholic parochial schools to place the latter under the department so far as health regulations are concerned in the same manner as the public schools. Hereafter, cases of diphtheria, scarlet fever, and other contagious diseases will be reported by the teachers in these schools and the pupils will be kept at home until they can present a certificate of health from a physician.

MASSACHUSETTS.

Dr. Ernest B. Young, Boston, was married on September 3 to Miss Grace Simonton, of Rockland.

The Wakefield board of health has ordered the local high school building closed until its sanitary condition has been so improved as to be satisfactory to the board.

Dr. George E. Chamberlain, Lawrence, who served during the Spanish-American war in Jacksonville, Savannah and Cuba, has been appointed acting assistant-surgeon in the army and is waiting orders.

The physicians of Lynn enjoyed an outing at Lynnfield, September 13, had a baseball match and a shooting contest.

The Hampden County Medical Society has recorded its disapproval of the reduced fees given by certain fraternal and benevolent societies, claiming that the medical practitioner should insist on at least the ordinary compensation instead of a stipulated sum per annum. Thus far, there was no room for litigation. It appears, however, that a patient who was sent by one of these so-called contract physicians to the Mercy Hospital in Springfield was refused admission to that institution unless the doctor in attendance withdrew from the case, which he finally consented to do for the sake of the patient, who required treatment which could be afforded only at a hospital. A suit will now be brought to ascertain whether the hospital staff could lawfully take this action under its charter, which provides that all patients shall be treated there who are brought to the institution by reputable physicians.

MICHIGAN.

Dr. George E. Grover, Evart, has sold his practice and will locate in Bay City.

Dr. R. C. Mahaney, who was graduated at Ann Arbor, this summer, has located at Owosso.

Dr. Andrew L. Swinton, Ontonagon, was married to Miss Ella Williams at Olivet, September 13.

Dr. James R. Arneill, Ann Arbor, was married to Miss Sara H. Taylor, at Los Angeles, Cal., recently.

The Michigan College of Medicine and Surgery, Detroit, began its fall term September 18. Prof. Robert H. Honner delivered the opening address.

A minimum standard has been adopted by the State Board of Registration and Examination, and the medical colleges of the state have been notified as to its details. It provides for a preliminary education equivalent to secure entrance into the freshman year of the university, including at least one year of Latin. The curriculum must comprise in lectures and teaching: Anatomy, 130 hours; physiology, 200 hours; chemistry and toxicology, 150 hours; pathology, 100 hours; therapeutics, 150 hours; histology, 60 hours; hygiene, 30 hours; practice of medicine, 390 hours; surgery, 195 hours; obstetrics, 120 hours; gynecology, 30 hours; bacteriology, 60 hours, and medical jurisprudence, 15 hours. The laboratory work must not be less than 240 hours in anatomy, 80 in physiology, 240 in chemistry and toxicology, 80 in pathology, 80 in histology, 48 in surgery and 120 in bacteriology. The clinical work must be reviewed by a committee of the board.

MINNESOTA.

Dr. Charles H. Norred, Minneapolis, who was appointed special quarantine officer by the board of health, several months ago, has resigned.

Albert Lea is agitating the question of a general city hospital, and two meetings have been held by the local profession in furtherance of the project.

Dr. J. Frank Corbett, bacteriologist of the Minneapolis health department, is seriously ill with diphtheria contracted while making cultures in the laboratory.

Dr. Mabel Austin has proposed to the St. Paul City Hospital board of control, to devote her services without compensation until June, as bacteriologist and pathologist to the hospital, provided the laboratory is so enlarged and equipped as to enable her properly to do the work.

Dr. Justus Ohage, health commissioner of St. Paul, has secured warrants for the arrest of a St. Paul butcher and the agent of a packing company for selling meat condemned as unfit for food. He has already obtained the passage of a resolution through the board of aldermen revoking the butcher's license.

The incorporation of the Medical Defense Association of Minnesota, whose object is to protect the interests of the medical practitioners of the state, is announced. The directors are Drs. James H. Dunn and John W. Macdonald; Minneapolis; Thomas McDavitt and Charles A. Wheaton, St. Paul, and others.

MISSOURI.

Dr. William H. Chrisinger has moved from Trenton and located in Princeton.

The Kansas City Medical College opened for its thirty-second annual session, September 12.

Compulsory vaccination of school children in the city is advised by Dr. Edwin E. Hunter, assistant health officer of St. Joseph.

The Medico-Chirurgical College, Kansas City, began its fourth year, September 12. Addresses were made by Dr. Blencowe E. Fryer on "The Pleasures of Medical Studies"; by Dr. Eugene R. Lewis, on "Now and Then," and others. A new $15,000 building for the college is to be erected during the present year.

NEW YORK.

Dr. Frederick M. Higgins, who has been practicing in Bozeman, Mont., has returned to Oswego.

Dr. William E. Palmer, Le Roy, was married to Miss Zilla Marietta Green, at Greigsville, September 12.

Dr. Charles E. White, Waterville, has moved to Rome.

Dr. Louis D. Masson has been appointed house physician at the Cohoes City Hospital.

Rome, during August, had 13 births and 23 deaths, of which cholera infantum caused 8. The sanitary inspector reported that the city water-supply was now uncontaminated.

The new census has surprised Binghamton by reducing materially her estimated population of 45,000. The new rating will increase the per thousand death-rate from 15.71 to 17.8 for last year.

Buffalo.

Dr. Sigmund Goldberg has returned from a three-months visit in Europe.

At a recent meeting of the medical section of the Buffalo Academy of Medicine, Dr. A. L. Benedict read an abstract from his essay on "Clinical Quantitative Estimation of Proteid Digestion in the Stomach," which was awarded the medal by The American Medical Association.

During August there were 509 deaths, as compared with 425 in the corresponding month in 1899. There were 32 deaths from consumption, 88 from cholera infantum, 42 from cancer, 17 each from apoplexy and meningitis, 29 from nephritis, and 13 each from inanition and typhoid fever. Of the deaths, 203 were children under 5 years of age, and 65 were 70 years old or over. There were 606 births during the month.

New York City.

Dr. Robert C. Miles has returned from a summer cruise.

Dr. William D. Farrell has located in Fort Dodge, Iowa.

Dr. L. I. Mason was recently married to Miss Lillian B. Thatcher,. also of New York.

Dr. John A. Horn discharged his colored servant, and a week afterward the latter tried to shoot the Doctor, who succeeded in disarming him.

The commissioners of the new State Hospital for Consumptives have selected a site at Big Clear, near Saranac Inn station. They admit that this is more expensive than the one at Dannemora, but they object to having the hospital associated with the state prison.

Mr. George D. Sweetser has left $5000 each to the Home for Incurables, Colored Home and Hospital, Woman's Hospital of the State of New York, House of Rest for Consumptives, New York Infant Asylum, New York Skin and Cancer Hospital and the Hospital for Ruptured and Crippled.

Roosevelt Hospital has just been provided with two electric automobile ambulances, each costing about $3000, and manufactured by the firm that made the pioneer automobile ambulance here for St. Vincent's hospital. It is announced that the New York and Presbyterian hospitals will soon have similar ambulances.

The ambulances of both Roosevelt and the Harlem Hospitals within the last few days have been in smash-ups, in which driver, surgeon and patient have all been injured. In one case the surgeon escaped with bruises and a severe scalp wound; in the other the surgeon had his leg broken and the driver sustained a fracture of one rib. In both instances street excavations were partly responsible for the mishap.

Dr. William N. Berkley, of Bellevue Hospital, has spent the summer studying the question of relation of mosquitoes to malaria. He is now conducting experiments on a man who is in Bellevue Hospital, suffering from a severe form of malaria. This man permitted a number of mosquitoes to draw blood from him, and thus contributed his mite to the cause of science.

The Bronx water famine is no longer a mere matter of inconvenience; physicians in that section report an unusual amount of sickness, which they think can be fairly attributed to the lack of a proper supply. It is rumored that this state of affairs is entirely preventable—is indeed a matter of politics. The citizens are thoroughly aroused, and have decided to take upon themselves the task of investigating the water-supply of their borough. They have already entered on this work with enthusiasm, and promise some interesting developments in the near future.

OHIO.

Dr. Charles E. Stewart, Sand Fork, has moved to Wellston.

Dr. Orville K. Hooper, Waverly, has located in Brooklyn, N. Y.

Dr. M. Howard Carmedy, Painesville, has returned after a prolonged absence in Great Britain.

The medical department of Western Reserve University, Cleveland, has under construction a new laboratory for clinical microscopy, and an isolating building for contagious diseases, both connected with Lakeside Hospital. The new pathological laboratory at Charity Hospital is now completed.

Cincinnati.

Dr. Mary Hawes, who was obliged recently to go to Denver for her health, has been made assistant to the chair of histology in Gross Medical College.

Dr. Harry F. Gau, has left for the East and Europe. He will spend some time at Johns Hopkins Hospital, Baltimore, going thence to New York, and subsequently to Europe, where he will remain two years.

Statistics just compiled by the secretary of state show that 2845 inquests were held in Ohio during the past fiscal year, an increase of 151 over the previous year. There were 122 homicides, 374 suicides, 117 deaths from intemperance, and the balance from accidents or unknown causes.

Dr. Frank Lamb, brother to the present senior resident surgeon at the Cincinnati Hospital, has obtained the interneship held by the late Dr. Herbert Elliot.

The city health officer has divided Cincinnati into 22 districts in order to determine the relative healthfulness of various localities. The statistics should show just what diseases are most prevalent. Following this plan, a health census of the city, for the purpose of determining the percentage of death and disease by districts will be made.

PENNSYLVANIA.

Dr. James G. Heading, Academia, was nominated for Congress, September 17.

Dr. Wentworth D. Vedder has been elected president of the Mansfield board of health.

Dr. Daniel G. Hersh, East Greenville, has purchased the practice of Dr. M. B. Oberholtzer, and has moved to Red Hill.

Dr. N. H. Rachlin, who has been serving as interne in Bellevue and Willard Parker hospitals, New York, has gone to Johnstown, as assistant to Dr. Louis H. Mayer.

The City of Allegheny and two firms of contractors are named as defendants in a suit for $10,000 brought by Dr. C. Le Roi Thompson, on account of a fall from a bicycle, by which his arm was broken.

At the annual meeting of the Trustees of the State Asylum for Chronic Insane of Pennsylvania, Wernersville, held at South Mountain, near Reading, September 10, Dr. Samuel S. Hill was re-elected superintendent for the ensuing year, Dr. Alexander W. Smith, and Dr. Laura Hulme, second assistant physician.

Philadelphia.

Dr. Andrew J. Downes has returned from Europe.

Dr. W. L. Rodman has been elected professor of surgery in the Woman's Medical College, but retains his former connection with the Medico-Chirurgical College.

Langdon Mitchell's dramatization of Dr. S. Weir Mitchell's novel, "The Adventures of Francois" is to be played at the Park Theater, beginning October 6.

THE SCHOOL MEDICAL INSPECTORS throughout the city began their work at the opening of the public schools, September 10. So far the city has made no appropriation for this work, which is purely voluntary.

THE J. B. LIPPINCOTT COMPANY has purchased land in East Washington Square upon which to erect its new building. The site was once occupied by the old Walnut Street Prison, in which American prisoners were confined during the British occupation of Philadelphia in the Revolution.

A CASE of smallpox was discovered in the Pulaskitown settlement, Germantown, September 22. The patient was at once taken to the Municipal Hospital and the house has been disinfected.

THE NEW ENTRANCE BUILDING of the Pennsylvania Hospital, to cost $60,000, is now far advanced and will be finished by December 1. The building consists of one story and basement, built of colonial brick. It has a depth of 88 feet, and is 45 feet wide. The first floor will consist of an entrance hall, and assembly room, and the basement will be divided into a kitchen, dining and other rooms.

AT A JOINT MEETING of the committee on office and the committee on hygiene of the board of education held a few days ago a complete set of rules were adopted looking to better hygiene in the public schools. Some of these were as follows: The temperature in the rooms should never be permitted to go under 65 nor over 76 F. When the weather will permit, the windows are to be raised at recesses for 10 minutes, and the windows are to be raised and the doors opened at the close of school. Sun should be permitted to shine in the school-room as much as possible. Spitting is prohibited.

THE TOTAL mortality of the city during the week ended September 22, was 356, a decrease of 74 over the previous week, and a decrease of 15 over the corresponding period of last year. The principal causes of death were: Apoplexy, 9; nephritis, 24; cancer, 12; cholera infantum, 21; tuberculosis, 39; heart disease, 40; appendicitis, 5; pneumonia, 16; suicide, 2. Typhoid fever, 41 cases, 5 deaths; scarlet fever, 12 cases, 2 deaths; diphtheria, 101 cases, 15 deaths.

THE WILL of the late Dr. J. M. Da Costa, which was admitted to probate, September 24, devises to the Pennsylvania Hospital $5000 to endow a bed in the medical ward; to the Children's Hospital, $5000 to endow a bed in memory of his son, John M. Da Costa; to the College of Physicians, $5000 to endow the Publication Fund; to the University of Pennsylvania, $5000 for the Professors' Retiring Fund, and to the Sunday Breakfast Association, $1000. His collection of medical charts, models, pictures and drawings is left to Jefferson Medical College, and his extensive medical library, to the College of Physicians.

TEXAS.

DR. GEORGE A. TROTT, Georgetown, was married to Mrs. Donnie Gwinn, at Austin, September 13.

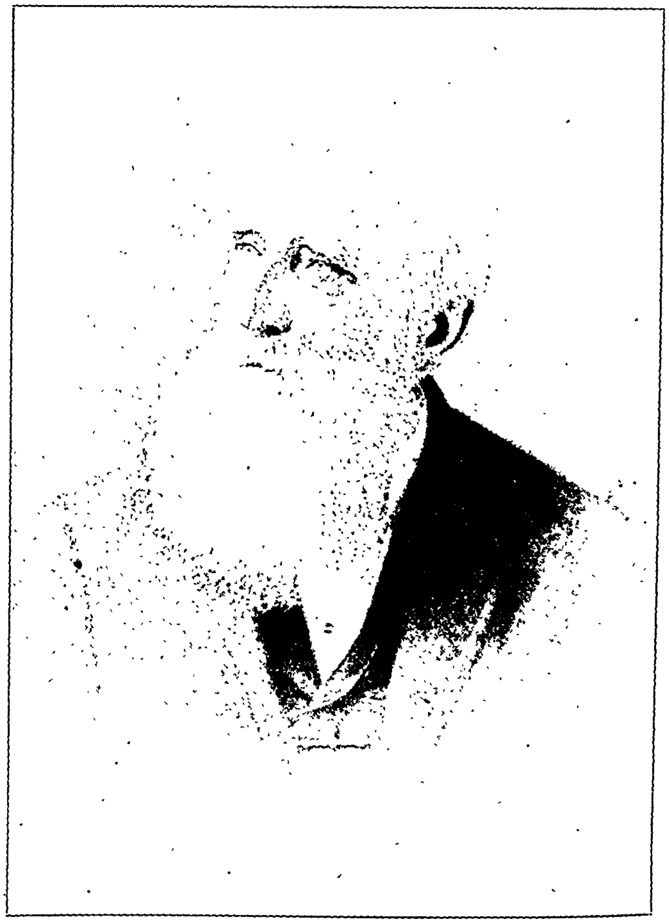
THE PUBLIC SCHOOLS for whites at Marshall have been ordered closed until further notice, owing to an outbreak of scarlatina in the town.

SEALY HOSPITAL, Galveston, which was reported to have been destroyed by the storm, suffered no harm aside from broken windows and drenching of certain rooms. The nurses' home, which adjoined it, was completely demolished. None of the regular inmates of the hospital died, but many died who were brought there in the emergency. The hospital sheltered several hundred refugees during the storm.

Deaths and Obituaries.

Dr. Alfred Stille.

Dr. Alfred Stillé, ex-President of the American Medical Association, whose death occurred September 24, was born in Philadelphia in 1813. His academic and medical education was received at the University of Pennsylvania, where he took his degree of bachelor of arts in 1832 and of doctor of medicine in 1836. He supplemented his college course by service as a resident physician in the Philadelphia and Pennsylvania Hospitals and by study abroad, in Paris and other European capitals. From 1844 till 1850 he lectured on pathology and the practice of medicine before the Pennsylvania Association for Medical Instruction. In 1854 he was elected professor of the theory and practice of medicine in the Pennsylvania Medical College, and filled the chair until 1859. In 1864 he was chosen to a similar position in the University of Pennsylvania, and held it until his resignation in 1884. He was one of the founders of THE AMERICAN MEDICAL ASSOCIATION and one of the first secretaries, and was President at the meeting in San Francisco in 1871. Dr. Stillé is best known to the profession as a medical writer, though his career as a teacher was long and successful. His great work on therapeutics, which passed through a number of editions, was long the standard work on the subject, and his connection with the National Dispensatory has made his name almost a household word. Aside from these he published many notable papers and monographs, among which may be mentioned his work on cerebrospinal meningitis, one of the most often quoted of the earlier contributions to the subject. He was one of the partakers in the early movements of the American Medical Association to reform medical education, and published a brochure on the subject in 1845. Dr. Stillé's record speaks for itself; as a writer and a teacher he has made his mark on the medical history of the country, of which his career will form a not insignificant part.



Until the last few months Dr. Stillé's health had been remarkably good for one of his age, a paralytic stroke three years ago leaving no trace but a slight lameness. The immediate cause of his death was bronchitis contracted about six months ago. His great age was a hindrance to his recovery and he gradually failed. Last week his condition took a sudden change for the worse, and on Saturday it was evident that death was near, but he retained his faculties until the last.

Dr. Stillé was married twice. His second marriage occurred in June of last year to Miss Katherine A. Blakiston, who survives him. His son, Dr. Henry Stillé, is a prominent physician in San Antonio, Texas.

Hunter Holmes McGuire, M.D.

Dr. Hunter McGuire, whose death occurred at Richmond, Va., September 18, has been a leading figure in American medicine for the last thirty or forty years. Born in Winchester, Va., in 1835, himself the son of a physician, he received his first medical degree from the Winchester Medical College, in 1855. Desiring to still further complete his medical education, he attended lectures at the Jefferson Medical College in Philadelphia, and took his second degree of M.D. at Richmond, Va., 1860. On the breaking out of the Civil War he enlisted in a Virginia regiment, but was almost immediately commissioned as surgeon, and served in that capacity and as medical director under "Stonewall" Jackson, Ewell and Early throughout the war. He was the first on the Confederate side to inaugurate the recognition of medical officers as non-combatants and their release when taken prisoners. After the surrender at Appomattox he settled in Richmond, where he took the chair of surgery in the Medical College of Virginia, and filled the position until 1878, when the demands of his extensive practice compelled him to give up the active work of teaching. Since this retirement he had been increasing his surgical work and reputation, so that at his death he stood easily among the first in the specialty. In his state and throughout the South generally he was a leader in his profession, and there were few who had a record that so endeared them to their fellow citizens. Dr. McGuire was not a voluminous writer as compared to some, but his contributions to medical literature were nevertheless numerous and valuable, covering many departments of surgery. His abilities had been recognized at home and abroad, and he had held many high active and honorary positions. The estimation in which he was held is shown by his election to the Presidency of The American Medical Association in 1892, an honor shared by few; besides this, he had been Vice-President of the same body in 1881 and of the International Medical Congress in 1876. The other similar high positions he had filled are too numerous to mention; in all he served with dignity and honor. His death was not unexpected, as he had for months been in a very critical condition from a paralytic attack, which from the first caused the gravest fears as to its outcome. In his death his country has lost one of the foremost members of our profession.

Lewis Albert Sayre, M.D.

Dr. Lewis A. Sayre, the father of orthopedic surgery, died at his home in New York City after a long illness, September 21, aged 80 years. He was born February 20, 1820, at Bottle Hill (now Madison), N. J., of good revolutionary stock, his grandfather, Ephraim Sayre, having been a devoted patriot. He received his early education at Madison Academy and at Wantage Seminary, Deckertown, N. J., then lived for two years with relatives in Lexington, Ky., and was graduated in 1839 from Transylvania University. He determined to study medicine, although he had been destined for the ministry, and returning East studied under Dr. David Green in New York, attended lectures at the College of Physicians and Surgeons, from which he was graduated in 1842. His graduation thesis was on "Spinal Irritation." He was immediately appointed prosector to the professor of surgery and occupied that position until 1852, when he was appointed emeritus prosector. In 1853 he was made surgeon to Bellevue Hospital, and in 1859, surgeon to Charity Hospital. He was one of the organizers of Bellevue Hospital Medical College in 1861, and was given the chair of orthopedic surgery, fractures and luxations. From 1859 till 1866 he was resident physician of the city of New York, and during that period made many important contributions to the literature of hygiene and public health. He was one of the first to advocate the establishment of a national quarantine. In 1876 he presented a paper on "Morbus Coxarius" to the International Medical Congress and its treatment he illustrated by operating before the assembly. In 1877, by invitation, he visited Europe and was received as few American surgeons had been. He lectured and made demonstrations and operations at hospitals in London, Liverpool, Manchester, Birmingham and Cork. He received the honor of a resolution of thanks, passed by the British Medical Association, for demonstrations of the methods and details of his treatment of spinal curvatures. He was a prolific contributor to medical literature. His more extensive works are: "An Illustrative Treatise on Spinal Disease and Spinal Curvature," "A Practical Manual of Club-Foot" and "Lectures on Orthopedic Surgery and Diseases of Joints." He was one of the founders of the N. Y. Pathological Society, in 1844, of the N. Y. Academy of Medicine

and of The American Medical Association. He was Vice-President of the latter in 1866, and President in 1880. In addition he was connected in an active or honorary capacity with many American and foreign medical and surgical societies, including the British Medical Association, the Medico-Chirurgical Society of Edinburgh, and the Surgical Society of St. Petersburg. Dr. Sayre was a mechanical genius, and many of his inventions in the way of deformity apparatus, etc., are standard among orthopedic surgeons. He was created a Knight of the Order of Wasa, in 1871, by the King of Sweden in recognition of his services to a member of the royal family. He had been in good health until about a year ago, when he was attacked by inflammatory rheumatism, which, with other troubles incident to his advanced age, so exhausted his strength that he succumbed.

Joseph Neville, M.D., Omaha, Neb., died on August 18. Drs. Peck, Coffman, Tilden, Mercer, Peabody and Neville were the pioneer surgeons of Omaha. Drs. Coffman, Tilden, Peabody and Mercier still survive. Dr. Neville had suffered for a long period with chronic nephritis, but his death was due to cholera morbus, caused by fish ptomain. He was one of the oldest members of the Omaha Medical Society, which passed appropriate resolutions of condolence at its September 11 meeting.

David B. Hillis, M.D., died at his home in Keokuk, Ia., September 9, aged 75 years. He was born in Indiana and received his medical education in the medical department of Washington University, St. Louis, from which he was graduated in 1847. At the outbreak of the Civil War he was commissioned colonel of the 17th Iowa Infantry, and rendered distinguished service. At the close of the war he returned to Keokuk and resumed practice. From 1890 till 1899 he was president of the College of Physicians and Surgeons.

Henry L. Smyser, M.D., the oldest physician in York, Pa., died September 17, aged 75 years. He was a graduate of the department of medicine of the University of Pennsylvania in the class of 1847. He went to California in 1849; in 1856 served in the Russian army as surgeon-major through the Crimean War, and on his return was contract-surgeon in the United States army during the Civil War. At the close of the war he located in York.

Frank Warren Merriam, M.D., of New York City, died in Waterford, Conn., September 16, aged 46. He received his medical degree from the New York University in 1880, and served as an interne of the Charity Hospital, New York City, before entering on general practice. He retired on account of ill-health about six months ago. He vainly sought health at Hot Springs, Ark., and afterward in Europe.

Thomas M. Bowyer, M.D., died at Battle Creek, Mich., recently. He was a native of Virginia, and was graduated in 1853 from the medical department of the University of Pennsylvania, at Philadelphia. During the Civil War he served as captain of Bowyer's Battery. He had been in bad health for several years, and of late had practiced in Las Cruces, N. M.

Edward S. Armstrong, M.D., Perry, Mo., died September 8 from injuries received in a runaway accident the previous evening. He was 65 years of age. He was a graduate of the medical department of Washington University, St. Louis, 1867, and had practiced medicine in Perry for more than thirty years.

S. J. Love, M.D., who was one of the victims of a mysterious poisoning, died after an illness of two weeks, on September 4, aged 28. He was graduated from the Medical College of Virginia, at Richmond, in 1896, and had practiced since that time at Long's Store, N. C.

Alcinous J. Sanders, M.D., of Grand Island, Neb., died, September 13, aged 63. He was a graduate of Long Island College Hospital, Brooklyn, N. Y., in the class of 1863, and had practiced in Grand Island since 1880. He had been an invalid for four years.

W. L. Johns, M.D., died from lung disease at the home of his brother, Dr. H. M. Johns, Ennis, Tex., September 14. He formerly practiced at Alma, but had been traveling for some time in Mexico and the West in the vain endeavor to regain his health.

John McMahon Brown, M.D., a graduate of the University of Dublin in 1868, died from cardiac disease at his home in New York, September 12. For twenty years he was a physician in Dublin and London, but came to New York in 1888.

Alfred J. Masecar, M.D., died suddenly at his home in Monroe, Mich., September 16, aged 61. He was a native of Ontario, and was graduated in 1864 from the medical department of Victoria University, Cobourg, Ont.

Michael F. Honan, M.D., died September 12 at his home in LaGrande, Ore. He was graduated from Bellevue Hospital College in 1879, and had resided in LaGrande for more than twenty years.

Alvin H. Kerr, M.D., Pittsburg, Pa., died September 11, aged 37. He was a graduate of the medical department of the Western University of Pennsylvania, at Pittsburg, in the class of 1888.

George W. McLeod, M.D., died recently at Anderson, Ind., aged 66. He was a native of Kentucky, but had lived and practiced for many years in Indiana.

G. Ruban Lane, M.D., a graduate of the medical department of Grant University, Chattanooga, Tenn., in 1896, died at Flint, Ala., September 14.

Walter L. Hilliard, M.D., Asheville, N. C., died September 4. He was a graduate of Jefferson Medical College, Philadelphia, in the class of 1895.

Arnold Sellner, M.D., St. Louis, died September 14, aged 38 years. He was graduated from Beaumont Hospital Medical College, St. Louis, in 1888.

DEATHS ABROAD.

Prof. Dr. Wilhelm Wagner, a surgeon of ability, died recently at Koenigshuette.

Dr. Domingo Freire died recently at Rio de Janeiro. He was well known by his researches in yellow fever.

Dr. A. Hanau died at Constance, Switzerland, August 24. He was formerly docent of pathologic anatomy at Zurich, and devoted much study to the transmissibility of cancer.

Dr. Thomas Martyn Sibbald, R.N., died recently at Taku, China. He studied medicine at King's College, London, and obtained his M.R.C.S. Eng. diploma in 1875, and his L.R.C.P. Ed. a year later. At the time of his death he was fleet surgeon on board H.M.S. *Centurion*, Admiral Seymour's flagship. His death was directly due to his exertions in behalf of the wounded at Taku.

Therapeutics.

Catarrhal Tonsillitis.

℞.	Formalin	m. xv-xx	1-1	33
	Potassii chloratis	ʒi	4	
	Liquoris ferri chloridi	ʒi	4	
	Aquæ menthæ piperitæ, q. s. ad	℥iv	128	

M. Sig. Use as a spray three or four times a day.

FOR THE FEVER.

℞.	Quininæ hydrobromatis	gr. xii		75
	Sodii benzoatis	gr. xxii	1	50
	Salol	ʒi	4	

M. Ft. capsulæ No. xii. Sig. One capsule every three hours.

—*Sajous' Annual.*

Gastric Cancer.

To relieve pain of gastric cancer and assist digestion:

℞.	Ext. condurango fluidi	℥ii	64
	Acidi hydrchlorici diluti	ʒii	8
	Syrupi acaciæ	℥iv	128

M. Sig. Two teaspoonfuls in water before eating.

—*Exchange.*

Incontinence of Urine.

℞.	Potassii citratis	ʒiss	6	
	Spts. etheris nitrosi	℥ss	16	
	Aquæ, q. s. ad	℥ii	64	

M. Sig. One dessertspoonful every five hours until urine is clear. —*Encyc. Med.*

Gonorrhea.

℞.	Acidi carbolici			
	Acidi tannici, āā	gr. viii		5
	Glycerini	ʒss	2	
	Aquæ	℥i	32	

M. Sig. Use as an injection at night. —*Exchange.*

Mosquito Bites.

℞.	Acidi carbolici	gr. xxx	2	
	Glycerini	ʒiii	12	
	Aquæ rosæ, q. s. ad	℥viii	256	

M. Sig. To be locally applied whenever necessary. —*Exchange.*

Chafing of the Skin.

Where skin surfaces which are in apposition have a tendency to chafe, the following will be found useful:

℞.	Magnesii carbonatis			
	Zinci oxidi			
	Acidi borici, āā	ʒii	8	

M. Sig. Apply to the affected parts. —*Encyc. Med.*

Gonorrheal Vaginitis.

℞.	Methyl blue	ʒiiss	10	
	Alcoholis	ʒiiiss	14	
	Potassii chloratis	gr. iii		20
	Aquæ destil	℥vi	192	

M. Sig. Two or three tampons of cotton wet with this solution and introduce into posterior vaginal fornix, and retain for two days.

Hemorrhagic Metritis.

℞.	Ext. ergotæ fluidi	℥i	32	
	Ext. hamamelidis fluidi			
	Tinct. cinnamomi, āā	℥ss	16	

M. Sig. One teaspoonful every two hours. —Chase: *Med. News.*

Impetigo and Acne.

℞.	Acidi carbolici	gr. x		66
	Glycerini			
	Aquæ rosæ, āā	℥i	32	

M. Sig. Apply locally two or three times a day as a wash. —Gould.

Vaginal Antiseptic.

℞.	Betanaphthol	ʒiv	16	
	Alcoholis	ʒxxx	120	

M. Sig. Use a teaspoonful to the quart of warm water, previously boiled. —*Exchange.*

Fissured Nipples.

℞.	Tinct. benzoini comp	ʒii	8	
	Alcoholis	ʒiv	16	
	Aquæ camphoræ, q. s. ad	℥iii	96	

M. Sig. Shake and bathe the nipples, and apply freely after nursing.

La Grippe in Children.

℞.	Tinct. aconiti	m. v		33
	Sodii benzoatis	gr. xx	1	33
	Syr. lactucarii	ʒiss	6	
	Syr. aurantii	ʒv	20	
	Mucil. acaciæ	℥iiiss	112	

M. Sig. One dessertspoonful every three hours. —Perier: *Med. Record.*

Chloralamid by Rectal Injection.

℞.	Chloralamid	gr. xlv	3	
	Acidi hydrochlor. dil	m. ii		12
	Spts. vini	m. xv	1	
	Aquæ destil	℥iii	96	

M. Give by rectal injection to produce sleep. —*Agenda Ther.*

Oxyuris Vermicularis—Thread Worms.

In cases of oxyuris vermicularis Sidney Martin employs the following:

℞.	Tinct. rhei			
	Magnesii carbonatis, āā	gr. iii		20
	Tinct. zingiberis	gtt. i		06
	Aquæ destil	ʒiii	12	

M. Sig. At one dose, and repeat four or five times a day, according to action. —*Ther. Monatshefte.*

Corns.

℞.	Ext. cannabis indicæ	gr. xv	1	
	Acidi salicylici	ʒiiss	10	
	Olei terebinthinæ	m. lxxv	5	
	Acidi glacial. acetici			
	Cocainæ—alkaloidae—āā	gr. xxx	2	
	Collodion, q. s. ad	℥iii	96	

M. Sig. Apply a thin coat every night on top of preceding one. —*Exchange.*

Rectal Injection of Iodids and Bromids.

The *Therapeutic Gazette* contains an extract from an article of Kobner, published in the *Journal de Méd. de Paris*, in which he recommends the following formula when iodids and bromids can not be taken by the mouth:

℞.	Potassii iodidi			
	Potassii bromidi, āā	gr. xlv	3	
	Ext. belladonnæ	gr. iv		25
	Aquæ destil	℥vii	224	

M. Sig. Add two tablespoonfuls of this solution to three ounces of warm water and inject into the lower bowel once, and if necessary, twice a day.

If a stronger solution is desired, the following prescription may be employed:

℞.	Potassii iodidi			
	Potassii bromidi, āā	ʒii	8	
	Ext. belladonnæ	gr. vii		5
	Aquæ destil	℥x	320	

M. Sig. An ounce of the solution may be given in three ounces of water twice a day by rectal injection.

Societies.

Coming Meetings.

Golden Belt Medical Society, Enterprise, Kan., Oct. 4.

Idaho State Medical Society, Boise, Oct. 4-5.

Utah State Medical Society, Salt Lake City, Oct. 4-5.

Wyoming State Medical Society, Cheyenne, Oct. 9-10.

Mississippi Valley Medical Association, Asheville, N. C., Oct. 9-11.

Iowa State Association of Railway Surgeons, Des Moines, Oct. 11-12.

Vermont State Medical Society, Rutland, Oct. 11-12.

Tri-State Medical Society of Alabama, Georgia and Tennessee, Chattanooga, Tenn., Oct. 11-13.

New York State Medical Association, New York City, Oct. 16-18.

American Public Health Association, Indianapolis, Ind., Oct. 22-26.

Medical Society of Virginia, Charlottesville, Oct. 23.

The McKean County (Pa.) Medical Society met in Bradford, September 4, and elected Dr. John B. Mason, Mt. Jewett, president.

The Medical Society of City Hospital (St. Louis) Alumni met September 20, and discussed the new City Hospital in its various phases.

The Lebanon County (Pa.) Medical Society met at Lebanon, September 11, Dr. Ezra Grumbine, Mt. Zion, in the chair. The discussion was on "Dysentery."

The Olmsted County (Minn.) Medical Society met at Rochester, September 11. Dr. Rollo C. Dugan, Eyota, read a paper on "Hyperemesis Gravidarum."

The Warren County (Pa.) Medical Society, at its meeting September 12, elected Dr. William V. Hazeltine treasurer, vice Dr. John Curwen, resigned.

The York County (Pa.) Medical Society met September 7 at York, Dr. Alfred A. Long, York, read a paper on "The Coal-Tar Products," and Dr. Isaac C. Gable spoke on the prevalence of typhoid fever in York.

The Winnebago County (Ill.) Medical Society met at Rockford, September 11. Dr. Thomas N. Miller presided. In his address Dr. Harold N. Moyer, Chicago, declared that the general practitioner was now the people's doctor and that the day of the specialist had passed.

The Ann Arbor (Mich.) Medical Club met at the house of Dr. John A. Wessinger. Dr. Victor C. Vaughan gave an exhaustive address on "Hydrophobia," which was discussed by Drs. Frederick G. Novy and Conrad Georg.

The Salt Lake (Utah) Medical Society was addressed at its September 10 meeting by Health Commissioner King, who spoke on the sanitary conditions of the city, and advised the erection of a large central garbage crematory, with smaller crematories in various districts of the city.

The Mercer County (Mo.) Medical Society was organized at Princeton, August 30, and the following officers elected: Dr. Fred S. Blachly, Modena, president; Dr. Dolph D. McHenry, Princeton, vice-president; Dr. Charles R. Buren, Modena, secretary; and Dr. David W. Reed, treasurer.

The Montgomery County (Ill.) Medical Society was reorganized at Hillsboro, after a lapse of thirteen years, with a membership of about forty. The following officers were elected: Dr. William W. Douglas, Hillsboro, president; Dr. James F. Blackwelder, Litchfield, vice-president; Dr. Joseph M. Trigg, Farmersville, secretary and treasurer.

The Pasadena (Cal.) Medical Society held a symposium on "Typhoid Fever," September 11. Dr. Alfred C. Croftan discussed the clinical microscopy and chemistry; Dr. Francis F. Rowland, the etiology; Dr. Fordyce Grinnell, the symptomatology; Dr. Lorenzo Lockard, the laryngeal manifestations; Dr. George S. Hull, the eye and ear symptoms, and Mrs. David B. Van Slyck and Charles G. King, the treatment.

The Inland Empire Clinical Society met at Spokane, Wash., September 4. Dr. Alexander F. MacLeod read a paper on "The Paste Treatment of Certain Varieties of Cancer," and Dr. James M. Powell, one on "Autoinfection." Dr. Powell was elected a member of the board of censors, vice Dr. Nathan A. Goddard, removed from the city, and Dr. Charles P. Thomas was elected permanent secretary in place of Richard H. Van Heusen, who had also left Spokane.

The Muskingum County (O.) Medical Society held its annual meeting at Zanesville September 13, and elected the following officers: Dr. William A. Melick, Zanesville, president; Dr. William R. Hosick, Adamsville, first vice-president; Dr. Charles A. Dunn, Stovertown, second vice-president; Dr. David J. Matthews, Zanesville, recording secretary; Dr. Anna M. Hill, Zanesville, corresponding secretary, and Dr. Wilbert C. Bateman, Zanesville, treasurer.

The Rhode Island Medical Society held its quarterly meeting in Providence, September 6, president George D. Hersey in the chair. A paper was presented by Dr. Barnard Arnold, Rockland, on "The Eruptions attending Epidemic Influenza"; Dr. Halsey De Wolf, Providence, gave a brief account of the work of the Lying-in-Hospital during the past fifteen years, and John W. Mitchell spoke on the same subject. The president delivered the annual address on "The Medical Library as a Factor in Medical Progress."

The Medical College of Indiana, medical department of the University of Indianapolis, opened September 25. The changes in the faculty include the promotion from lectureships to professorships of Drs. Frank B. Wynn, pathology; John W. Sluss, anatomy; John F. Geis, toxicology and forensic medicine; Edmund D. Clark, surgical pathology, and William M. Wright, surgical anatomy, minor and clinical surgery. The new lecturers are Drs. Charles E. Ferguson, diseases of women; Norman E. Jobes, osteology; Alois B. Graham, gastro-intestinal surgery; Roscoe H. Ritter, physiology; Frederick R. Charlton, genito-urinary diseases, and Prof. M. E. Crowell, of Franklin College, physics. It is the intention of the faculty to erect a building for chemical and biological laboratories during the year.

The Upper Des Moines (Ia.) Medical Association met in Estherville, September 12. President Dr. Quintus C. Fuller, Milford, delivered the annual address, and papers were read by Dr. A. Anderson, Estherville, on "Forceps in Obstetrics"; Dr. G. G. Fitz, Emmetsburg, on "Therapy of Oils," which elicited considerable adverse discussion; Dr. Maurice E. Wilson, Estherville, on "Rheumatism; Dr. Charles S. Shultz, Lake Park, on "Preventive Inoculation"; Dr. Charles B. Fountain, Spirit Lake, on "The Doctor and the Druggist"; Dr. Gilbert G. Cottam, Rock Rapids, on "Fractures"; Dr. Royal G. Hamilton, Ocheyedan, on "The Use of Kerosene in Intestinal Obstructions," and Drs. Charles S. Shultz, Lake Park, and Charles B. Fountain, Spirit Lake, discussed the use of oxygen gas in pneumonia.

The Pennsylvania State Medical Association held its fiftieth annual meeting at Wilkesbarre, Sept. 18-21, President George W. Guthrie, Wilkesbarre, in the chair. About 200 delegates were present from all portions of the State. The visitors were welcomed by Mayor Nichols and Dr. Henry M. Neale, Upper Lehigh, President of the Luzerne County Medical Society. A large number of interesting papers were read and received due discussion. A resolution was introduced by Dr. Lewis H. Taylor, Wilkesbarre, calling on the Legislature to enact a law to prevent the pollution of the streets of the state. The following officers were elected: Dr. Thomas D. Davis, Pittsburg, president; Dr. William B. Ulrich, Chester, first vice-president; Dr. Lewis H. Taylor, Wilkesbarre, second vice-president; Dr. Augustus A. Eshner, Philadelphia, third vice-president; Dr. Martin L. Herr, Lancaster, fourth vice president; Dr. Cyrus L. Stevens, Athens, secretary; Dr. Walter L. Pyle, Philadelphia, assistant secretary; Dr. George Dunmire, Philadelphia, treasurer. The next meeting will be held in Philadelphia, the third Tuesday in September, 1901.

American Association of Obstetricians and Gynecologists.

Thirteenth Annual Meeting, Louisville, Ky.

Sept. 18-20, 1900.

Dr. Rufus B. Hall, Cincinnati, in the chair.

Dr. Lewis S. McMurtry, Louisville, welcomed the Association on behalf of the local medical profession. The Address of Welcome was responded to by President Hall.

ERRONEOUS OBJECTIONS TO BILATERAL INGUINAL CELIOTOMY AND SHORTENING OF ROUND LIGAMENTS VIA DILATED INTERNAL INGUINAL RINGS, AND ITS SUPERIOR ULTIMATE RESULTS IN SIMPLE AND COMPLICATED ASEPTIC RETROVERSIONS OF UTERUS.

Dr. A. Goldspohn, Chicago, read a paper with this title. He laid stress on cutting only through the skin and fat and making the required opening through the aponeurosis, the canal and the internal ring bluntly. The ring is very readily dilated sufficiently to admit one or, if needed, two fingers, and to admit of drawing out the tube and ovary for the exercise of the highest degree of delicate and exact conservative surgery on them without doing violence to their supports. The wound is closed in four layers, *à la* Bassini. In the second layer the round ligament becomes placed as in a sandwich between the posterior surface of Poupart's ligament and a good bundle of elastic muscle at each stitch, which makes hernia impossible and saves the ligament from strangulation while it holds it firmly enough against Poupart's ligament to secure a broad union. Hernia has not followed the writer's operation in fully 125 cases that he has examined or from which he has had reports. As the internal inguinal ring is just in front of the normal lateral location of the ovary and ampulla of the tube, these organs and the posterior surface of the uterus can be reached by one finger in a one-inch opening here, as well as by two fingers in a two-inch opening in the linea alba midway between the symphysis and the umbilicus; and for the necessary access to the pelvic wall to shorten the proper suspensory ligament of the ovary and tube, this small opening serves well; while a large median ventral incision and much traumatism of viscera by that route would be needed and by the vagina it can not be done at all. The round ligaments are always present, if the uterus is. He has never had a death from the operation; but one case died from a serious renal complication that was not previously discovered, owing to an exchange of samples of urine by a nurse. Thorough shortening of the round ligaments via their natural channels and anchoring forward—not laterally—is the only operation that has been proved, or is likely to be proved, to stand what the writer demands as the normal standard for all operations of this kind, and has called it the "double test of pregnancy," i. e., that they do not embarrass gestation and complicate labor, which is the single test, but also do not permit a recurrence of retroversion of the uterus after one or more subsequent labors. The difficulties in diagnosis as to presence of pus are no more than proficient gynecologists will meet successfully, and doubtful cases can be cleared up by ten to fourteen days in bed with temperature douches and extensive fomentations. The scars being in the groins, and covered mostly by hair, are not seen like regular laparotomy scars.

Dr. Charles G. Cumston, Boston, in the discussion, said that from his experience in operating both by the abdomen and vagina, as well as from a pathologic standpoint, it has always seemed to him that serious lesions of the adnexa, such as the essayist had treated through a bilateral inguinal incision, were usually out of reach, and that these lesions could be dealt with more easily and satisfactorily through a median, a posterior or anterior vaginal incision. Simple, uncomplicated cases of retroversion are rare. The Alexander operation in the so-called simple cases of retroversion can be greatly improved by an additional operation through the cul-de-sac.

Dr. Edward J. Ill, Newark, N. J., called attention to the modified operation which was proposed by Dr. H. W. Longyear, of Detroit, at the meeting of the Association last year.

Dr. J. Henry Carstens, Detroit, rarely sees cases of plain, uncomplicated, non-adherent retroverted uteri that require the Alexander operation. The complicated cases of retroversion require some other operative procedure.

Dr. W. E. B. Davis, Birmingham, Ala., referred to the indications for performing the Alexander operation, and called attention to the class of cases in which it should be performed.

Dr. Frederick Coggshall, Boston, said he had performed over a hundred Alexander operations in combination with some other operative procedure.

Dr. Rufus B. Hall, Cincinnati, thinks that the old operation of anterior fixation or ventrosuspension of the uterus is not as popular as it was a few years ago. Soon it will be done only in rare instances. He believes, however, that a modified operation, such as that advocated by the essayist, is based on rational surgical principles, and thinks that the author is working in the right direction.

ROUND LIGAMENT VENTROSUSPENSION OF THE UTERUS.

Dr. D. Tod Gilliam, Columbus, Ohio, in this paper, said that various devices have been resorted to for restoring and holding in place the retrodisplaced uterus. All of these have been faulty and many absolutely prejudicial. The need of the hour is an operation that will utilize the natural supports of the uterus, that will insure a fair amount of mobility, that will adapt itself to the various functions of the uterus—pregnancy and parturition—and that will be lasting in its results, and withal easy of execution. Profiting by the work of Ferguson along this same line, he has devised an operation which he thinks fulfils all these indications, and solves the problem most satisfactorily. The steps of the operation are as follows: 1. A median abdominal section three or four inches in length at the usual site between the umbilicus and pubis. 2. The adhesions are broken up and the fundus brought forward, after which the patient is placed in the Trendelenburg position. 3. Seize the round ligament on one side and bring it to the opening. This may be done either by the fingers or by the aid of forceps. 4. Carry a thread under the ligament at a distance of about one and a half inches from the uterus. The free ends of the thread are brought out of the abdomen and secured by clamp forceps. 5. The other round ligament is secured in the same way. 6. Expose the rectus muscle near the lower end of the incision by retracting its sheath and by rolling it out of its sheath on the tips of two fingers applied to the peritoneal surface under it. 7. Select a point one inch external to the margin of the incision and something over an inch above the pubis, through which the perforating forceps, specially devised for this purpose, is thrust into the peritoneal cavity. The two fingers already in the cavity guard the instrument in its passage and place the thread which surrounds the ligament within its jaws. 8. The perforating forceps is now withdrawn, after removing the clamp forceps from the thread, and both thread and ligament are brought up through the perforated wound in the abdomen. 9. While the ligament is held taut, fasten it into the wound by a to-and-fro catgut suture passed deeply through the ligament and including the tissues on either side. 10. Treat the opposite side in the same manner and close the median abdominal incision. Only a small loop of the ligament should be drawn up through the wound.

A CASE OF COMPOSITE TERATOMA OF THE OVARY.

Dr. W. E. B. Davis, Birmingham, Ala., read a paper on this subject. The author is in doubt as to the nature of the tumor, notwithstanding the above diagnosis was made by pathologists of high standing.

Mrs. N., aged 34, married, was the mother of three children, had always menstruated regularly, except when pregnant or nursing. She noticed a growth in the abdomen two years ago. She had menstruated in January before the growth was noticed, and then missed her periods until March, at which time she menstruated or bled very freely for two weeks. She then missed periods until the following October, with no untoward symptoms except an attack of colic in August. The movements were noticed before August. After October she menstruated regularly until the following January, missed her periods then until October 24, 1899, when a child was born. She has not menstruated since. After the birth of the child at term, the tumor developed quite rapidly, and on May 7, 1900, she was operated on, and was discharged as cured June 9. The tumor was quite large and had a pedicle nearly two inches in breadth, quite thick, and which was attached to the uterus. The fetus was so large and so well formed that the essayist was of the opinion that there had been an ectopic gestation, with rupture of the gestation sac and the expulsion of its contents into the cavity of a pre-existing ovarian cystoma. From the history of the case, the diagnosis had been made of an old ectopic pregnancy. He is still inclined to that opinion.

TREATMENT OF CHRONIC CYSTITIS BY CURETTEMENT OF BLADDER, AND INSTILLATIONS OF CORROSIVE SUBLIMATE.

Dr. Charles Greene Cumston, Boston, read this paper and therein drew the following conclusions: 1. Sublimate instillations will often produce a very great improvement in the distressing symptoms met with in both tuberculous and non-tuberculous cystitis, such as a diminution in the frequency of micturition, a decrease of the pain, an increase in the capacity of the bladder and an improvement in the condition of the urine. In some cases a complete cure may be had. 2. When the instillations fail to produce the desired effect, curettement of the bladder is indicated in both tuberculous and non-tuberculous cystitis. 3. In gonorrheal cystitis instillations of sublimate are very efficacious and rapidly subdue pain. 4. Under favorable circumstances a radical cure of primary tuberculous cystitis may be obtained by curettement when the vesical lesions are localized and the kid[illegible] fr[illegible] disease. Curettement per urethram will n[illegible] to re[illegible] the entire surface of the bladd[illegible] extensive they should be direct[illegible] omy. 5. Much relief may be afforded to a large number of patients suffering from tuberculosis of the bladder, but who on account of the advanced stage of generalized infection are in no condition to undergo a more radical operation. 6. When cystitis is due to a prolapsus of the genital organs, and when hysteropexy, combined with anterior and posterior colporrhaphy does not relieve the bladder symptoms, curettement of the bladder, followed by sublimate instillations, is the proper treatment.

Dr. A. Goldspohn does not believe that infiltrations, etc., of the bladder can be recognized by the curette at an early stage of the diseased process. With this instrument the operator can not detect beginning ulcerations or papillomatous growths in this organ. Curettement of the bladder is entirely different from that of the uterus, in that the operator does not receive the tactile information of intelligence from this instrument in the bladder that he obtains from it in curetting the uterus. Scraping the bladder, therefore, is done largely at random, without any touch sensation to govern the operator as to how little or how much surface he shall curette. Under such circumstances it is not rational to assume that the mucous lining of the bladder will be evenly and uniformly curetted. Uneven surfaces or small areas would be left untouched. In the treatment of infectious cystitis, not tubercular, he has obtained good results from a solution of .5 to 1 per cent. of oil of cloves in water.

Dr. J. Henry Carstens agrees with the last speaker that there are certain points in the bladder that can not be reached by the curette. He has had cases of tubercular, gonorrheal and septic infections of the bladder which have yielded to the judicious application of permanganate of potash.

Dr. Edwin Ricketts has never tried this method of treating cystitis in the female, but it seems to him plausible, and he is inclined to try it.

Dr. Rufus B. Hall directed attention to the danger of overdistention of the bladder with injections. Distention of the organ up to the point of causing discomfort to the patient should be the limit of safety.

Dr. James T. Jelks concurred in the statement of Dr. Carstens that permanganate of potash is an invaluable remedy for infective disease of the bladder, particularly of the gonorrheal variety. A solution of 1 to 6000 is strong enough to begin with, the strength being increased in accordance with the indications of the particular case.

Dr. T. J. Crofford, Memphis, has performed curettage of the bladder several times. If the inflammatory process is confined to the neck or thereabouts, there is very little difficulty attending the curettement of that area of surface. No inflammatory zones would be left to cause further trouble.

Dr. Goldspohn does not wish to be understood as opposing curettement of the bladder *in toto*, but believes it ought to be done under the guidance of the eye or tactile sense.

Dr. Cumston, in closing, referred to the pathology of bladder lesions and said they were almost always situated in the trigonum, consequently this is the portion of the viscus which the operator should strive to reach. If the whole bladder surface is involved, suprapubic cystotomy is the operation of choice, and curettement in such a case would do very little, if any, good. He uses the cystoscope in the treatment of this class of cases.

FOUR CASES OF PERFORATED GASTRIC ULCER.

Dr. Henry Howitt, Guelph, Ont., read this paper. The first two cases occurred years ago before the operative procedures were commonly known, and had the usual termination, one dying within twenty-four hours from the commencement of the illness without having had a single symptom indicating the existence of the trouble. The other two reported by him are of recent date, and the patients were saved by timely operations. In one the operation was devoid of any serious difficulty, but in the other the abdomen contained gas and a large amount of pus, the colon was enormously distended, requiring to be opened, and collapsed before the stomach could be reached. There existed also the remains of a ruptured abscess cavity below the transverse portion of larger bowel, the walls of which were formed by it together with the coils of small intestine and omentum. This had its origin probably in a slight leakage which occurred days before the final rupture. The orifice of the ulcer was of sufficient caliber to admit his little finger, and was situated in front close to the pyloric valve. The surrounding parts were so thickened, dense and nodular as to exactly resemble carcinoma of the pylorus and adjacent parts of the stomach. A section nearly two inches in length had to be removed before the ulcer could be closed. The intestines were previously eviscerated to permit of the room necessary to reach the part and to expose the pools of pus in the pelvic flanks and other places difficult to reach. The upper portion of the jejunum was anastomosed by means of a Murphy button to the anterior wall of the stomach. Before doing so care was taken to allow for every possible movement without causing tension of the proximal arm of gut. After the anastomosis was completed, the arm of intestine above was stitched to the wall of the stomach an inch or more to the right and a little above the line of the button. This procedure in his opinion overcomes the acute angle and its ill-effects. Drainage-tubes were inserted through perforations made in the flanks well to the back and in the lower abdomen close to the pelvis, to the outer side of the right rectus muscle. The sutures were all removed, except two in the middle of the wound opposite the umbilicus, on the seventh day. Three hours later the patient had a sneezing fit, and the wound tore open from the upper angle to the umbilicus, exposing the situation of anastomosis, and coils of bowel protruded. It was restitched an hour later without anesthesia, and no ill-effects followed. The patient made an uneventful recovery, and is now for the first time in eighteen years free from gastric distress.

Dr. Richard Douglas, Nashville, Tenn., has had two cases of perforating ulcer of the stomach in which he urged operation, and while preparations were being made to operate on one of them, the patient died. In the other operation was refused. Death ensued some time later. Post-mortem examination in this case revealed a perforating ulcer on the posterior wall of the stomach; while in the other case the ulcer was confined to the lesser curvature.

Dr. James F. W. Ross, Toronto, called attention to the difficulty attending the diagnosis of gastric ulcer in some cases. He had operated successfully on one case of perforating gastric ulcer. The patient did not know that she had anything seriously the matter with her.

Dr. Charles Greene Cumston mentioned a case in which there was an ulcer of the stomach and one in the vagina, of embolic origin, associated with arteriosclerosis.

Dr. Edwin Ricketts narrated the case of a woman, 48 years of age, who had had a gastric ulcer for three years. Under rectal alimentation she gained sixty pounds in flesh. Subsequently she committed some indiscretion in diet, was again taken sick, and consulted another physician, who made a diagnosis of cancer of the pylorus. She went from bad to worse, and finally died. Post-mortem examination revealed a perforating gastric ulcer the size of a lead pencil, situated on the anterior surface near the pylorus.

Dr. A. Vander Veer, Albany, spoke of two cases of gastric ulcer which ultimately resulted in carcinoma of the pyloric end of the stomach. From the number of cases in which he has done gastrointestinal anastomosis, he is satisfied that he has had to deal with the cicatrices resulting from gastric ulcers in many instances.

SOME POINTS REGARDING THE SURGERY OF THE GALL-BLADDER.

Dr. A. Vander Veer, Albany, N. Y., presented the above paper:

No great reliance is now placed on jaundice as a positive symptom. Four interesting and instructive cases are reported, and the following conclusions drawn: 1. An early diagnosis of cases. 2. In suppuration of the bladder with adhesions, a most thorough examination should be made from within by digital exploration and use of the probe for any possible deep-seated calculi. 3. In prolonged operations on the common duct or hepatic ducts, where adhesions are present, and it is difficult to close the incision, after removal of the calculus; drainage through the peritoneal pouch by means of the lumbar stab is advisable. 4. When the patient is suffering seriously from cholemia, with marked ecchymotic spots over the body, intense itching, the blood found in a septic condition, an operation is not to be encouraged; it is too late in the vast majority of cases for the patient to recover. 5. General practitioners as well as the surgeon should place more earnestly before the patient and friends the dangers of repeated attacks of gall-stone irritation resulting in cancer of the ducts, stomach or liver.

DIAGNOSIS OF ECTOPIC GESTATION BEFORE RUPTURE, BASED ON ELEVEN CASES.

Dr. James F. Baldwin, Columbus, said that in a large number of cases an early diagnosis is entirely feasible and will be made as a routine when the attention of intelligent general practitioners is sufficiently directed to the subject. He said that while there are no pathognomonic symptoms of tubal pregnancy, the following points will usually be found in these cases: The patient gives a history of several years of sterility (many exceptions); she has missed a menstrual period, two of them (numerous exceptions); she has noticed some unusual pains in the pelvis, boring, griping, or colicky in character, these pains being situated usually in the region of an ovary. She has perhaps within a few days of the time of consulting her physician had a more or less irregular hemorrhage; perhaps has discharged pieces of membrane which she supposed indicated an abortion, and consults her physician with the idea that such is the case, owing to the hemorrhage and the pain and the suspicion of an existing pregnancy. Possibly, however, there has been no suspicion of a pregnancy, as the woman has accepted her sterility as incurable and has dismissed from her mind such a possibility.

On making a vaginal examination, if the conditions are favorable, the examiner will find on one side of the uterus, or back of it, a fusiform, quite well-defined cystic tumor, about the size of a pullet's egg or a little larger. This tumor will probably be quite tender on pressure, will be quite symmetrical in outline, and will usually be distinctly pulsating. When such a tumor is found in a woman in whom we have reasonable grounds to suspect a pregnancy; when the uterus at the same time is found somewhat enlarged, and having the feel of pregnancy, but not enlarged as much as one would expect in a pregnancy of so long continuance as the history indicates, a presumptive diagnosis of tubal pregnancy is warranted, and the matter of an operation should be carefully and without delay considered. To render the early diagnosis of ectopic pregnancy possible, it is necessary for physicians to learn to suspect it, and to examine patients with that suspicion in mind. The physician who, without making any examination, tells all middle-aged women who come to him complaining of irregular hemorrhages that they are merely having the change of life, will not likely make an early diagnosis of cancer of the uterus, and he will probably tell patients who come to him with symptoms of ectopic pregnancy that they are merely threatened with a miscarriage. He will make no further investigations, and will hence uniformly fail to make a diagnosis. The physician, however, who, having in mind the possibility of an ectopic pregnancy, thoroughly examines all patients whose history and symptoms point to this condition, will in a large proportion of cases make a correct diagnosis and by prompt intervention will achieve a signal triumph for himself and his profession.

Dr. Charles A. L. Reed said that to make a diagnosis of tubal pregnancy before the time of rupture, it is necessary to have the patient under observation constantly for a considerable length of time. He had encountered such a case about seven years ago, the details of which were narrated.

Dr. L. H. Laidley said the only diagnosis of ectopic pregnancy he had ever made was in a case of cancer of the uterus where there was no rupture. He did not suspect the existence of it until he had removed the tubes and had found indications of a developing fetus within the tubes.

Dr. Zinke, Cincinnati, thinks the diagnosis of ectopic gestation is easy in some cases if the gynecologist has certain symptoms to guide him, namely, loss of blood, either scanty or profuse, attended with pain, and a tumor, pulsating in character, found on one side of the uterus. In other instances, however, the diagnosis is very obscure, particularly in those cases in which the ectopic gestation is complicated with a normal pregnancy. Such a case was narrated.

Dr. D. Tod Gilliam said that if the gynecologist could diagnose most cases of ectopic gestation before rupture has taken place, it would prove a great boon to womankind. A distinction between tubal pregnancy and inflammatory conditions should always be borne in mind.

Dr. J. Henry Carstens does not think cases of extrauterine pregnancy are as common as the profession generally supposes. The average general practitioner with a good practice observes but very few such cases in a lifetime. He spoke of the difficulty in diagnosis, and said that when this condition was expected and operated for, something else is found.

SURGICAL TREATMENT OF UTERINE DISPLACEMENTS.

Dr. Charles A. L. Reed, Cincinnati, contributed this paper. Attention was called to a couple of modifications of technique in the management of a class of cases that is happily becoming less and less perplexing. It is not the author's purpose to discuss the relative merits of Alexander's and Mann's operations, nor to consider the ingenious technique of Ferguson. In a majority of cases of retrodisplacements that demand operation, the author believes that the intraperitoneal shortening of the round ligaments is the operation of choice. It has been his habit during a number of years to effect this by making an S-fold in the ligaments and stretching them thus folded to the parietal peritoneum along the line of Poupart's ligament. This method has yielded him better results than any which he has previously tried. He has, however, become convinced that the parietal fixation of the folded ligament is not necessary for the purpose of holding the uterus in its normal position, and that the technique devised by Mann is all that is required to accomplish this object. His application of this technique differs a little from that originally adopted by Mann, the modifications being those of convenience rather than of necessity. We give these modifications in the language of the author: ".In seizing the round ligament with hemostatic forceps for the purpose of folding it on itself, the tissues are frequently wounded. While the accident is not a serious one, it is certainly not desirable. The use of two hemostatic forceps for the purpose of effecting the fold makes the services of two hands of an assistant necessary. To obviate these objections, which though of minor importance are still objections, I have devised a forceps with four flat approximating prongs, the whole being an inch across. The prongs of the opposing blades approximate with sufficient force to hold the ligament, but not enough to induce tissue necrosis; while, when approximated, they are far enough apart to permit the passage of a medium-sized needle between them. The ligament brought up into the field of operation on the finger, is seized in its middle third by this instrument, which is then held in this position until all of the sutures are applied. These are inserted as follows: One interrupted, one fixing the loop of ligament to the cornua of the uterus; a similar suture is utilized to fix the outer fold of the ligament; a continuous suture is then passed between the prongs of the fixation forceps, its ends being obliquely tied after the instrument is withdrawn.

"A pathologic condition that often exists in cases of long-standing flexions and the persistence of which militates against the success of any fixation operation, consists of an atrophy of the concave wall and a hypertrophy of the convex wall at the point of flexure. In many of these cases, particularly when associated with diffuse fibrosis, the elongated and hypertrophied wall offers a persistent resistance to the maintenance of the normal axis of the organ. To overcome this I have, for some time, [illegible] a cu[illegible] segment from the hypertrophied wall, [illegible] on [illegible] Thi[illegible] cuneo-hysterectomy, and which is applicable in either anterior or posterior flexions. To do this the patient is placed in the Trendelenburg position. All adhesions between the uterus and bladder, or between the uterus and other organs, are carefully broken up, any rents in the serosa that may be induced thereby being carefully stitched. The uterus is then brought toward the incision by gentle, but firm, traction and an ellipse of tissue about 1 cm. wide and having a length corresponding to the breadth of the organ is removed from the convex side at the site of flexure. Care must be taken not to carry this dissection into the cavity of the uterus nor to wound either the circular artery or the anastomosing branches of the uterine artery. Should the latter accident occur, it is best controlled by en masse ligatures, passed deeply into the uterine tissue at either end of the yet gaping ellipse. Retraction of the vessels generally prevents their isolation and closure by direct ligature which, when practicable, is always the preferable method. After all hemorrhage, except mere capillary oozing, is controlled, the margins of the ellipse should be carefully approximated and closed by a continuous animal suture with two or three interrupted ones of the same material. The uterus is then dropped back, and after pausing a moment to make sure of complete hemostasis, the abdomen is closed without drainage. A further modification of this operation that I have practiced with satisfaction in anteflexion consists in stitching a reef of the posterior surface of the uterus. I have been able by these combined methods to relieve the most distressing and persistent symptoms, vesical, uterine, ovarian and neurotic, due to otherwise intractable anteflexion of the womb."

AMERICAN.

1. **Neurasthenia.**—The distinction between hysteria and neurasthenia is first noted by Eskridge; the latter is not a disease, but simply an exhausted and irritable state of the nerve centers. Its causes are numerous, but the psychic far outweigh the physical in this regard; mental depression, anxiety, etc., are more exhausting than mental work alone. Various diseases, pelvic disorders, indigestion, eye troubles, etc., and even bad teeth may have an agency in causing it. Hodge, Mosso and others have shown that it has a real pathology in cellular changes. Eskridge reviews the symptoms in detail, motor, sensory, ocular, mental, visceral, etc., and remarks as regards its diagnosis that we must differentiate between it and organic disease, hysteria, incipient melancholia and paresis, and lastly between genuine and simulated symptoms in medicolegal cases. This last is not always easy; but a slow or normal pulse-rate is not indicative of neurasthenia, and if it is not increased by exercise or pressure over alleged tender points the presence of traumatic neurasthenia is dubious. The prognosis is generally good as regards life, the chief unfavorable conditions are heredity, early appearance of the disorder, and its long duration. The danger of the drug habit in these cases must also be considered. The most important points in treatment are prevention, removal of exciting causes, etc. In the developed disease the treatment consists of rest, partial or absolute, and in many cases isolation. In the severer cases, with absolute rest, suitable diet, preferably skimmed milk, carefully regulated, is advised, and generally also isolation.

2. **Post-Operative Mental Disorders.**—Posey reports 24 cases of mental disturbances following operations on the eyes, and thinks these would be more frequently observed but for the fact that hypnotics are generally freely and promptly used on the first appearance of mental symptoms. The type is rather uniform, a mild restlessness passing soon into an active hallucinatory delirium, readily controlled by narcotics; in no case was there permanent damage. He thinks the causes are chiefly psychic, preoccupation of the patient's mind with the idea of his state and the psychic effects of the operation itself.

3. **Postcritical Temperature in Pneumonia.**—Fisher reports three cases of postcritical temperature in pneumonia in young children, which he analyzes as follows:

1. That a postcritical rise in temperature took place in all the cases, and that the temperature was somewhat uniform as to time, height, and duration.

2. That while the ratio existing between the respirations and the pulse during consolidation was reduced to an enormous extent, the ratio existing during the postcritical rise in temperature was increased.

3. That these conditions being true, there must have been some cause common to all.

4. That the rise in temperature bore a direct relation to the physical signs marking beginning resolution.

5. That the rapidity with which this secondary rise reached its highest point bore a direct relation to the extent of liquefaction.

6. That the rise in temperature was followed by an improved state of the affected area.

7. That as the condition in the affected area improved the temperature reached normal.

In conclusion he says that he believes this secondary rise to be a frequent one, depending on the absorption of a degenerated albuminoid mass containing fever-producing bodies. It is a condition which can be diagnosed, the diagnosis of which gives a great deal of satisfaction, and allays much uneasiness, not only to the physician, but to anxious parents and friends.

7. **Joint Disease.**—In the conclusion of his paper Phelps holds that the action of carbolic acid, as he employs it, is by uniting with albumin of the tissues, forming an antiseptic albuminoid or albuminate. His method is described as follows: The abscess cavity is laid open. The opening into the capsule is found and enlarged and the joint explored. If there is extensive bone disease, the incision is lengthened and the capsule of the joint freely divided for half or two-thirds of its entire circumference, the head of the bone pulled out from the socket, the curette freely used, and the joint thoroughly irrigated with bichlorid solution, one to one thousand. The joint is now filled with pure carbolic acid. It is [illegible]ed t[illegible] ain o

minute by the watch, after which the joint is thoroughly washed out with pure alcohol, and finally the alcohol is washed away with a 2 per cent. solution of carbolic acid. Instead of packing the wound or sewing it up, or introducing the collapsible rubber drainage-tube, he uses the largest glass tube that the cavity will take, which extends down to the joint and is just flush with the skin. This tube not only admits of perfect drainage, but enables the surgeon to see, day after day, just what is taking place in the joint. If further suppuration or extension of disease takes place, it is usually treated through this large glass tube by curetting and the use of carbolic acid and alcohol. Packing can be introduced through the tube to secure perfect drainage from the joint. These tubes vary in size from half an inch to two inches and a half, and they are of various lengths. A drainage-tube for a small child should be about an inch in diameter. In other words, the glass tube is fitted to the parts, as large as they will take, and one can readily see the immense advantage the surgeon has day after day if he can examine the diseased area down to the very bottom of the joint. The tube is worn until granulations fill in from the bottom of the wound. He removes diseased bone freely, but in his seventy cases thus treated he excised the head twenty times, while with the old methods he would have done this at least fifty times. His results are certainly good; he does not regard the carbolic acid, however, as a specific but as simply an auxiliary to good surgical work.

9. **Malignant Disease of the Larynx.**—Delavan analyzes and criticises the statistics of laryngeal operations for malignant disease, showing not altogether discouraging results. He reiterates, however, his earlier expressed opinion that the indiscriminate performance of capital operations on the larynx should cease, and suggests a careful scientific test by the most experienced and successful operators with the best appliances and assistance, with thorough following up of their cases. Then, he says, "it will soon be learned whether the radical extirpation of laryngeal epithelioma is a justifiable procedure or whether, as seems probable, the practical necessities of these cases must be met by means less hazardous to the life and comfort of the patient and more certain of complete and lasting success. Let us hope that the triumphs of iodid of potassium and the toxins of erysipelas may find their parallel in the successful remedy for epithelioma."

10. **Telephone Paralysis.**—Rice reports two cases of partial vocal paralysis apparently due to excessive use of the telephone, and suggests caution against its faulty use, or in case of its producing symptoms of nervous exhaustion.

12. **Snake Poison.**—This article is of considerable length, and only a few of its important points can be noticed. It describes the different kinds of venomous snakes, the various poisons, their physiological effects according to the different origins. It calls the sequela of the cobra bite an acute bulbar paralysis of the most furious and vehement type, while the poison by the viper snake has an analogy in acute ascending spinal paralysis, the last stage of which exhibits alike bulbar symptoms and inhibition of respiration. There is no question but that snake poison is both a nerve and a blood poison. It acts directly on the germicidal power of the blood, which accounts for the rapidity of decomposition. It has been an often-recommended custom to suck the wound or apply cups. He does not advise this procedure unless free scarification is first performed. Ligatures are useful in preventing absorption. This is the first recommendation in the treatment. The chances of neutralizing the poison are limited and the question is: What can we do to hasten the excretion? The kidneys are probably themselves affected, hence it is doubtful whether we should try to increase their activity. Diaphoretics have also had dubious results. It seems probable, however, that a certain amount of the poison is eliminated through the stomach; to give emetics may be a rational treatment. The author seems to think that the use of saline solution transfused into the veins is a somewhat promising measure, and a trial of artificial respiration is justifiable. Strychnin, which has been claimed to be a specific, has been extensively used, but the results are not convincing. In conclusion the author speaks of the use of immunizing the serum and its promise in the future treatment of these accidents. To sum up, the most commendable treatment, he says would be that one or more tight ligatures should be made above the wound, followed, perhaps, by deep scarifications; then injections of antivenene, if at hand. If the latter can not be had, injections should be made of a solution of hypochlorite of lime, 1 to 60, at several points near the bite and elsewhere. Stimulation, if necessary, by either strychnin or atropin or alcohol; hypodermoclysis of physiological saline solution; lavage of the stomach; artificial respiration for hours; and, not least of all, continuous encouragement of the victim, for a deep mental prostration goes together with the physical depression of the nervous centers.

13. **Erosions of the Stomach.**—Quintard reports a case of gastric erosion and sums up his conclusions, which are similar to those of Drs. Einhorn and Pariser, as follows: "1. That from time to time we see patients in whose stomach washings are repeatedly found small fragments of the gastric mucous membrane; on an average one to four of such pieces are found in a washing, their size varying from 2 to 7 cm. long and about 2 to 3 cm. wide; that the repeated finding of such pieces of mucosa in the wash water shows that we are dealing with a case of erosion. 2. That such erosions occur under varying pathological conditions, and that as a consequence the functional signs vary accordingly. 3. That the exact etiology and pathology of such erosions are at present not definitely known; that in the great majority of cases at least where such tiny fragments of mucous membrane are found in the wash water the patient gives a definite and peculiar clinical history distinct from that of round ulcer or from the exulceratio simplex described by Dieulafoy. 4. That as a consequence these cases should be regarded as a distinct class clinically and treated as such."

14. **Tuberculosis of the Testis.**—The chief point in Moschcowitz's paper is that the radical operation for removal of a tubercular testis includes also the removal of the vas deferens and the seminal vesicle. He shows that the same may be detached surgically by three separate routes: 1, by the inguinal route; 2, by the sacral route, and 3, by the perineal route. A comparison of the three methods he thinks will result favorably to the latter, as it has certain advantages over the others. Operation by the inguinal route seems to be very difficult and the extensive stripping off and not impossible injury to the peritoneum can not be an indifferent matter, and the extreme depth in which the operation has to be carried out bars an inspection and treatment of the possible infected prostate. The sacral route in any of its numerous modifications is so extensive that it must be considered complicated and dangerous.

15. **Liver and Elimination.**—Davis refers first to a former paper in which he pointed out the importance of the liver as an organ of nutrition. In his article he attempts to show that this organ is also the most important eliminative organ of the body.

16. **Talipes Calcaneus Paralyticus.**—Gibney, after reporting several cases, says that almost any appliance which is worn night and day, the management of which is taken completely out of the patient's hands, should bring good results. He has used mostly plaster of Paris and is somewhat prejudiced in its favor, but he can readily see how other dressings may be equally effective.

17. **Occupation and Tuberculosis.**—The etiology of tuberculosis is investigated by Freudenthal. He admits that statistics show that there is an increase of tuberculosis with a diminution of income. The most important thing, however, he thinks is occupation, and he has studied 1576 cases treated at the Montefiore Home in New York during the past ten years, especially noting the occupation of each, and found that tailors are particularly liable to the disease. This may be due to

their bent position, lack of proper exercise and other causes, and he expresses his opinion elsewhere that consumption is primarily a trophoneurotic affection of both a general and local nature, and that the invasion of the tubercular bacilli takes place at a later stage. He quotes Dr. Solis-Cohen as not of the opinion that the tubercle bacillus of itself originates the disease. He thinks this notion is spreading here and abroad, although not perfectly correct. In his opinion he says that occupation has an agency in the etiology of pulmonary tuberculosis in so far as it is sedentary and involves confinement within doors.

18. **Giant Cells.**—The chief aim of Warthin's article is to point out the confusion which exists in the recognition of the giant cells found in the pulmonary vessels, and the fact that at present there are no means of differential diagnosis as to whether these cells are of placental, spleen, or bone-marrow origin, and that the significance of such metastasis needs to be cleared up by further investigation.

19. **Stomach Disturbances and Post-Apoplectic Temperature.**—Winter believes that the continued high temperature of apoplectic cases, at times irregular in its fluctuations, may be dependent entirely upon the absorption of infective material in the alimentary canal and that the best treatment is the use of hydrogen dioxid. He mentions several cases where this treatment was adopted and thinks that they demonstrate positively that the temperature following the apoplectic stroke is due in part to this absorption. It has been his practice to give the drug combined with an equal quantity of chemically pure glycerin.

20. **Radical Cure of Hernia.**—In the statistics of 98 cases of hernia in his own practice Dr. Warren includes 74 of inguinal hernia, 7 of femoral hernia, 12 of umbilical hernia and 5 of ventral hernia, all operated on between 1898 and 1900. He separates them into two groups, those operated upon between 1888 and 1894 and those subsequent. There is quite a notable showing in favor of the latter; the percentage of septic operations is decidedly lessened in the latter period. He finds that silk has given better results than catgut. As regards recurrence, following the same rule as to the time of operation those subsequent to 1894 show that improved technique had an important influence upon the result. The percentage of perfect results is nearly as good as that laid down by Bull and Coley in their last article in the "International Text-Book of Surgery." The age and station in life are noticed as influencing the results. In children there is always a chance of cure by the truss, and children who have parents capable of exercising constant and intelligent care can be treated mechanically, but when the chances of such care are uncertain, or there are any complications, operation is advisable. Warren disagrees with Bull and Coley in their statement that fifty years is the age limit for operation in adults. Certain points in the technique of the operation are noticed, such as the emptying of the sac, removal of omentum, preparation of the skin beforehand, which is of great importance, as it is difficult to render it perfectly sterile, etc.

21. **Actinomycosis.**—Actinomycosis is probably, according to Porter, a less rare disease than commonly supposed. Examination by microscope is absolutely necessary for a positive diagnosis. He reports eight cases. It is practically impossible, he thinks, to make a clinical diagnosis of the disease. Recurrent abscesses about the jaw, not connected with tubercular glands, should arouse suspicion. The presence of the so-called sulphur granules in the discharge is not by any means conclusive and the microscope should be depended on. With reference to treatment, two facts, he says, speak strongly for the self-limitation of the disease in the majority of cases. 1. Though it can not be a rare affection, few cases enter the hospital with advanced actinomycosis of the jaw, and it seems therefore certain that many recover after simple incision of the abscess, and even through a natural rupture of it. 2. It is surprising to find, on microscopic examination of sections, how infrequently the colonies are found in the walls of the abscesses, though the pus contained many graules. The surrounding connective tissue probably proves an effective barrier to the spread of the disease. Many cases are cured by simple opening. The individual case and the severity of the infection must determine the choice between curetting and cauterizing and a more radical excision. Iodid of potash in doses of 20 grains three or four times a day has distinctly influenced some cases for good and should be used in connection with the local treatment.

27. **Pelvic Reflexes of the Heart.**—Robinson holds that the heart is particularly affected by diseases of the generative organs of women. He knows of no organs so manifestly disturbed in the menopause, and he figures out the mechanism with the various sympathetic ganglia and their connection with the automatic cardiac ganglia.

32. **Anatomical Relation of the Neuron to Nervous Diseases.**—Barker gives an interesting historical review of the rise and progress of the neuron theory and in conclusion offers his own views in the following: The formulation of the neuron doctrine was the equivalent of applying the doctrine of cell-units to the nervous system. The actual application to the nervous system at so late a date of a doctrine long known and generally appreciated for the other tissues of the body is explicable by the fact that it has been only recently that it has been possible to replace the mistaken conception of the extent of a nerve-cell formerly held by the true conception. If the term "nerve-cell" called up in mind the idea which we now hold of the biologic unit in the nervous system there would be no necessity for the use of the word "neuron." But until the text-books have been expurgated and the nomenclature employed by teachers and writers becomes more precise, some word other than "nerve-cell" would seem necessary. Any one who has the idea of "contact-relation" inseparably connected in mind with the term "neuron" would do well to give up the use of the word and to use "nerve-unit" or "complete nerve-cell' in its place. But for those who have never considered the theory of contact-relation as a necessary part of the neuron doctrine, but have regarded the neuron as the unit in the nervous system corresponding to the cells in other parts of the body, the term can be definitely retained and even employed with reverence on account of its historical significance.

33. **Pathologic Changes in the Neuron.**—Spiller's article is an elaborate one, which is not easily abstracted in detail. He finds that on the whole there is a tendency for the whole neuron to undergo alteration when it is attacked by disease or injured experimentally, but that one portion may be more resistant than the rest and may recover even though at first affected, although the end in union with the cell-body may finally atrophy. The earlier in life the lesion occurs the less the resistance. From these facts we have some evidence of the individuality of the neuron. The restriction of any degeneration to any particular set of the neurons is discussed at length in the light of his own and others' observation, and he finds that there is no doubt that this does exist, but that tertiary degeneration, understanding by that term degeneration of another series of neurons resulting in secondary degeneration of a series of the neurons nearer the origin of the impulses, do not seem to be very frequent. There is no positive evidence apparently of degeneration of the cells of the anterior horn from lesions of the posterior roots, and he knows of no evidence that disease of a sensory neuron ever results from disease of a motor one. The fact that degeneration may actually pass from one neuron to another does not prove that neurons do not exist. It is certainly not common for systemic disease to spread irregularly to neighboring areas.

34. **The Conception of the Nervous Diseases and the Neuron Doctrine.**—Sachs finds that the neuron theory is of "distinct assistance in the interpretation of toxic disease affecting at one and the same time the peripheral and central nervous systems, while in some instances involving only one or the other, and not both parts; it had shed some light on the perplexing questions of the relations of the

gressive muscular atrophy, and on the early morbid changes in tabes. It may be of some further help in our understanding of combined scleroses. More than this can scarcely be claimed for it; if it shall have accomplished all of this, and shall be able to stand the test of further sane criticism, it will be entitled to the consideration it has already received."

35.—See abstract in The Journal, xxxiv, p. 977.

39. **Insane Hospitals.**—Rogers reviews the development of insane hospitals and gives his ideas as to their construction and furnishings.

40. **Huntington's Chorea.**—After first reviewing the literature and opinions on this disorder with special reference to the pathologic findings, Good reports a case in detail which was observed by him in the Michigan Asylum at Kalamazoo. There was an atrophic brain with adherent thickened dura, thickening and opacity of the arachnoid, and other evidences of chronic inflammatory and irritative troubles. Marked pathologic changes were found in the cerebral cortex, the disintegration of the cells and engorgement of the vessels. During life there was a progressive dementia corresponding with some of these pathologic conditions.

41. **Paresis.**—Berkley reports a case of paresis in which death was caused during an attack of lobar pneumonia by multiple thromboses of the cerebral vessels due to changes induced by toxic products with multiplication of bacteria in the blood morphologically identical with the bacillus coli communis.

43. **Separate Provisions for Tuberculous Patients.**—Harrington's paper gives the statistics of tuberculous disease, especially pulmonary tuberculosis, in the different sections of the country, showing that while in the New England states the deaths from this cause are hardly greater than in the general population, it increases in other sections, and in the Southern states causes one-fifth of all deaths. He has made inquiries as to the separate provisions for cases of tuberculosis in insane hospitals and finds that in several states, notably in the West and middle West, active measures are being taken toward this end.

45.—**New York State Laboratory.**—Wise reviews the records of New York State as regards pathologic work in its asylums, and specially the recent differences of opinion between the director of the State Pathologic Institute and the asylum authorities. He maintains that the institution should be continued, but that its teaching function should be more thoroughly exercised than has been the case in the past.

46. **Suicide.**—The statistics of suicide in the different countries are touched upon by Styles, and he finds a marked increase with advancing civilization. While suicide, as a rule, is less common in catholic than in protestant states, the lowest figures are found in such almost exclusively protestant countries as Sweden and Denmark. He says little benefit comes from the laws making suicide an offense of any kind or from special legislation to prevent the act, while moral coercion is more or less effective.

47. **Studies in Neurasthenia.**—Pearce's article concludes from clinical and laboratory studies that neurasthenic conditions are associated with the circulation of such an irritant as uric acid in the blood. The vicious circle of disturbed metabolism being established in the toxic action on the nerve centers and the nutritional functions, the treatment should be directed to dietetic and nutritional methods, with a careful study of the individual idiosyncrasy in each case.

48. **Degeneracy.**—Everts finds that degeneracy is an inevitable consequence of civilization with its marked deviation from the original, or typical, human conditions. If by remedy we mean that the degenerate can be regenerated, there is none, but we may rest assured that providence is working in its way for the general progress of the race.

50. **Degeneracy in the Army.**—Woodruff points out the conditions of degeneracy that are observed among recruits, some of them slipping through by careless examination and becoming the black sheep of the army and the deserters. He gives a number of illustrations of this type, and in conclusion he mentions the army musicians as showing some marked variations from the average soldier. With the high musical sense there seems to be a liability to inferiority in some other ways, for they possess physical stigmata in far greater proportion than does the average soldier. They have to be managed by entirely different rules of discipline.

57. **Enuresis in Children.**—The physiology and causes of enuresis and irritable bladder in children are noticed by Bierhoff, and he considers that it is a result, as a rule, of a combination of conditions, the exciting cause being an abnormally increased irritability of the mucous membrane, most marked at the sphincter and sometimes in addition at the trigonum visicæ, or sometimes, in the male, of the prostatic urethra, and the cause of the heightened reflex irritability is to be sought either in a hyperemia or an inflammation of the vesical neck, the sphincter, or deep urethra, either singly or in combination. He has observed this condition in adults and believes that in children the cause is the same. In the normal bladder the mucosa has a low grade of sensibility and the tonic contraction of the sphincter is voluntarily inhibited, but in the abnormal hyperemia of the inflamed bladder the nerves are responsive to a far weaker stimulus, and added to this an increased nervous irritability from general systemic conditions, the effect is readily explained. He reviews the various reflex causes, etc., and their relation to treatment, in detail.

58. **Infantile Scurvy.**—Gilbert describes the symptoms and reports cases of this disease, and considers it is caused by the use of any single food, excepting mother's milk, continued for too long a time. The artificially prepared proprietary foods, of which there are so many in the market, are especially to blame. The remedy is simply fresh, wholesome food, with fruit juice.

60. **Etiology of Tuberculosis.**—McClintock reviews the theories as to the cause of tuberculosis and states the problems that are not yet fully solved in regard to it. He shows some of the difficulties in recognizing the cause that produces it, and says that we must remember in testing guinea-pigs, for example, that we are using animals very many times as susceptible to inoculation as man is. Because we have tuberculous milk, and the feeding of it in large quantities to guinea-pigs will produce the disease, it does not follow that this is the index of human danger from the same cause. We have yet no satisfactory explanation of the latency of tuberculosis. Some authorities believe that there must be an undiscovered spore-stage of the germ which may lie dormant for years, some authorities holding that this spore is the cause of all infection. He notices the recent views of Blos and Volland as to juvenile tuberculosis and the importance of predisposition. The number of those who are satisfied with the statement that the tubercle germ is the sole and sufficient cause of tuberculosis, the pure infectionists, grows less, he says, each year. He thinks that we will eventually find that some certain chemical constitution of tissue, a diathesis, if you please, is essential in the production of tuberculosis and that back of the tubercle germ lies this essential cause.

62. **Some Causes of Appendicitis.**—Walker points out that the vermiform appendix is in the first place a rudimentary organ of low vitality. It has a great absorptive power and poor nutritional facilities. The appendix being a small hollow viscus, when once inflamed it is liable to become strictured and encourage further trouble. The possibility of its becoming bent or kinked is also a danger. The great danger, however, he thinks, is the possible extension of a catarrhal inflammation from the cecum to the appendix and its subsequent invasion by more or less virulent germs.

64. **Pichi.**—Aronstam describes the botanical character of Fabiana imbricata, Ruiz and Pav, and its chemistry. He finds it contains minute quantities of: 1. A crystallizable alkaloid of bitter taste and neutral reaction, forming salts with acids, that he calls fabianin or pichin. 2. A neutral principle rich in

carbon, insoluble in water, tasteless and inert. 3. A fluorescent body analogous with esculin and classed among the glucosids. 4. A volatile oil. 5. A bitter resin on which the action of the drug depends. It is best used in the form of a fluid extract in combination with an alkaline aromatic and in doses of 10 to 40 minims every three or four hours. It is a stimulant and alterative to secretions in general, and a sedative to the mucous membranes, especially to the urethral mucosa, and has a high reputation in Chili in the treatment of urinary diseases. He has found it valuable in urethritis. It is said to expel calculi by its stimulating action on the muscular fibers of the urethra. He reports a case in which it was used in urethritis.

69.—See abstract in The Journal of July 7, p. 51.

70. **The Sac in Large Inguinal Hernia.**—The object of this paper is to emphasize one point in the technique of operation for very large inguinal hernia. What the author understands by very large inguinal hernia varies from the size of a child's head to an adult's head or larger, and the special point is management of the sac. In small hernia the sac is almost invariably removed, but in these cases it is so large, its walls so thickened, and its connection with hypertrophied tissue so much more intimate that its removal is therefore attended with danger of laceration and frequently with more or less troublesome oozing of blood or hemorrhage. Harris reports several cases in which instead of attempting to remove the sac from the scrotum he has allowed it to remain, and in two of the three there was no trouble whatever. In one there was a thrombosis, hemorrhagic insufflation of the testicle and sloughing. The first impression would be that in leaving so large a sac cysts or hydrocele would develop, but such has not been the case in his own experience or in the cases reported by Kramer. The advantages of this treatment are: 1. Saving of time during the operation. 2. Avoiding danger of sloughing of tissue. 3. Less danger of sepsis.

71. **Submersion in the Treatment of Wounds.**—The use of the hot bath in poisoned wounds, to which attention has recently been called by Fraser, is here noticed by Hodges, who claims that he has been the only American advocate of the treatment since the publication of Dr. Frank Hamilton, over twenty-five years ago. His extensive experience with the procedure, he claims, warrants the following practical conclusions: 1. Continuous submersion even for long periods—two or three months if necessary—is altogether harmless. 2. That it may be easily secured anywhere by anybody possessing an ordinary degree of ingenuity. 3. It will almost instantly limit infectious gangrene and control the resulting septicemia and spanemia. 4. It will quickly relieve the pain and discomfort of phlegmonous inflammation or cellulitis. 5. It will speedily and readily reduce temperature and pulse and overcome the consequent depression of the patient's vital forces. 6. The temperature of the bath is immaterial, except when below that of the room it more promptly reduces fever and many bacteria will not develop at this temperature, while such as do so, develop less vigorously than at a slightly higher temperature.

72. **The Diazo Test.**—Salisbury describes the diazo reaction and its clinical application and finds that it is of value in a number of diseases, especially typhoid and tuberculosis; in the latter it may serve a valuable purpose in estimating the stage of the disorder. He thinks it should be more frequently used by the practitioner.

77. **Club-Foot.**—The general belief that club-foot is incurable in the adult is contested by McKenzie, who has had experience with a number of cases averaging 26 years of age, of which he gives the particulars and illustrates a few. In the cases reported there was no operative interference other than subcutaneous cutting. The average time from the first operation until the patient was able to walk and be about was three months. From his experience he believes that neither operation on the bone nor open incision is called for to relieve the condition excepting in a very small proportion of cases, less than 5 per cent., and the result is better where there has been no cutting other than the subcutaneous one. The treatment is no longer than on patients where the open incision is made. Whatever method is adopted any deformity of the foot should be fully corrected before the relation of the foot to the leg is interfered with. In all the twenty-eight feet referred to, the result is very encouraging, and the age of some of these patients, 30 and 43 years, with satisfactory results, renders it comparatively certain that age by itself is not a serious barrier to treatment.

80. **Exploratory Incision in Obscure Brain Lesions.**—Cockburn reports several cases of operation on the brain, one of which revealed nothing especial though improvement followed. He thinks that exploratory incision might be more frequently resorted to with advantage when distinctly localizing symptoms are not present. If after all the modern remedies have been tried, all constitutional conditions excluded, and the patient fully understands the experimental nature of the procedure, he thinks the exploratory incision is justifiable.

84.—This article has appeared elsewhere. See The Journal of August 11, ¶ 16, p. 385.

85. **The Islands of Langerhans.**—The following are the conclusions in Opie's article: 1. The islands of Langerhans are composed of cells having the same origin as those of the glandular acini but forming structures which are independent of the secreting apparatus and in intimate relation with the vascular system. 2. In the splenic end of the cat's pancreas they have a definite position within the lobule, each of which contains one of these structures. 3. In the human pancreas they are more numerous in the splenic extremity or tail than elsewhere. Similar variation in their number is observed in cats and dogs. 4. Prolonged stimulation of the gland does not, as claimed by Lewaschew, transform groups of acini into islands of Langerhans.

86. **Connective Tissue in New Growths.**—White has studied the character and the distribution of various kinds of connective tissue, by different methods. His article is accompanied with handsome illustrations of the findings of some of these. His conclusions are as follows: 1. Elastic fibers are frequently present in new growths: in the stroma; among the cells; around the blood-vessels, and in breast tumors around the lactiferous ducts which have been included and invaded by the growth. 2. When present they are usually in connection with pre-existing elastic-tissue elements in the original tissue in which the growth has arisen. 3. Sarcomata present a large increase in connective tissue and possess an exceedingly fine intercellular network. 6. The digestion methods present a possible means of diagnosis between carcinomata and sarcomata in doubtful cases. 7. Uterine myomata have a very large amount of connective tissue both of a white fibrous and reticular nature, possessing a connective-tissue capsule for each muscle-cell; and would be more correctly termed fibromyomata.

88. **Congenital Moles.**—The literature on the nature of nevus cells and the transformation of moles to malignant growths has been studied by Whitehead, who reports two cases. He thinks it will serve to call attention to the fact that tumors may spring from congenital moles which present the same processes as those going on in the melanotic tumors, with the exception that they totally lack true melanotic pigment.

89. **Inorganic Ferments.**—Jones notices a paper bearing this title by Bredig and Mueller von Berneck, which points out certain analogies between the action of ferments and the contact-action of metals. In order to determine whether there was any close relation between the action of organic ferment and finely divided metals they studied the decomposition of hydrogen sulphid, etc., which reduce quite considerably the action also by finely divided metal. Jones reviews the chemical equations showing that the decomposition of hydrogen dioxid by colloidal platinum is a *monomolecular reaction, the platinum itself not entering into it. He finds a still more striking analogy* between the action of platinum and [illegible] in the action of certain poisons such [illegible]

drogen sulphid, etc., which reduce quite considerably the action of platinum on hydrogen dioxid. He thinks there has been enough done to show that this is a very promising field for investigation. and while it is impossible to say to just what it may lead, it is a step in a direction which is full of promise as possibly throwing light not only on chemical and physical, but also on biological problems.

97. **Dilatation of the Stomach.**—Robinson calls attention to a cause of stomach dilatation in visceral ptosis by pressure on the duodenum by the superior mesenteric artery, vein and nerve. He has studied this subject for several years and illustrates his paper with diagrams or sketches showing the mechanism. He has not found any records in the literature of this cause having been noticed and therefore considers it as an original observation by himself.

98.—See also abstract No. 58, above.

106. **Chronic Kidney Disease.**—Two kinds of the common, or at least commonly recommended, treatment of contracted kidney are noticed and also the recommendation of the milk diet and alkaline waters, which have been extended into regular drink cures at favorite health resorts. One point mentioned is the regulation of the allowance of albumin, especially the condemnation of red meats for this class of patients. Snyder thinks there is no basis for this, but that it has simply been handed down from one treatise to another without any reasonable evidence or argument in its support. The most important point, however, is the question as to the restriction of liquids. In nearly all the newer works there is either nothing said as to the amount of liquids to be allowed or they recommend a liberal allowance of them for the better flushing of the kidneys. After six years' careful study of the subject Snyder believes that very often patients with contracted kidneys can be helped to a very great extent by the restriction of their consumption of fluids. This is most shown in advanced stages of contracted kidney in which attacks of cardiac asthma have already appeared and there is, besides hypertrophy of the left ventricle, considerable dilatation. He believes that the practice of flooding the system with fluids in this condition is of immediate injury to the patient and mentions cases where he has seen this result. His conclusion, which he thinks entirely justified by his clinical and experimental studies, is that in the case of patients with contracted kidneys neither in the stage of relative euphoria, nor in the stage of beginning cardiac weakness, nor in chronic uremic phenomena, is elimination of the most important products of tissue metamorphosis ever impaired through lessening of the liquids to 1¼ quarts per day. In no single observation was this the case, though in a few instances there was the contrary result, viz., the increased elimination of nitrogen and urinary salts with the lessening of fluids. As regards albumin, the absolute daily amount of the urine fell off with the smaller injection of fluids and in practice the proportion of albumin is exclusively and erroneously considered. This fact is important, as otherwise one might be led through the lessening of the liquid to erroneously think that the albumin had been greatly increased.

108. **Unusual Symptom of Appendicitis.**—The special symptom here noticed by Thomas was observed by him in a boy of 16, in connection with perforation, which was relieved by operation. The symptom consisted in intense pain about an inch back of the meatus urinarius on the under surface of the penis. The mechanism suggested by the writer is that it is a reflex from the appendix transferred through the hypogastric plexus.

109. **Climate in Tuberculosis.**—Crosson's article is a statement of the advantages of New Mexico as a sanatorium for the tuberculous, and he thinks that region will be the resort of the future for the victims of this disease.

112. **An Unrecorded Case.**—Baier reports quite fully, though lacking some details which could probably have been furnished had she been the physician in charge and taking full notes at the time, the case of a clergyman whose symptoms were attributed at first to rheumatism and later to intermittent spinal inflammation, but which finally turned out to be one of intrathoracic tumor and osteomalacia. There was pressure from calcareous growths on the inside of the spinal canal, which probably was responsible for many of the peculiar symptoms observed. The patient finally succumbed from an attack of cholera morbus, and at the post-mortem, besides the lesions found, the viscera and organs were generally reported to be in a healthy condition.

The Lancet, September 8.

The Expectancy of Life in Cases of Cancer of the Breast. ARTHUR E. BARKER.—The author analyzes the statistics of operation for excision of malignant diseases of the breast and gives the following surgical axioms as those that have come to be pretty generally held and acted on in the treatment of these conditions: "1. An excision of the breast to be effectual must be early. 2. The overlying skin, subcutaneous fat, pectoral fascia, axillary fat and glands with the entire breast must be widely and deliberately removed. 3. During this dissection all division of carcinomatous tissue should be avoided, and, if inevitable, freshly sterilized instruments, etc., must be used. 4. As little direct handling of the parts to be moved as possible should take place. 5. Arrest of all immediate bleeding should be accomplished, preferably by forci-pressure, and, if not, by ligature; and subsequent oozing by elastic pressure and bandaging. Rest for the wound and the patient should be secured for at least two weeks. 6. All this extensive removal can be accomplished with but little risk to the patient in fairly early cases. 7. When the disease has infected the muscles palliation alone can be expected from surgical interference, and it is questionable whether very extensive operations involving risk from shock ought to be performed with only this end in view. Indeed, the apparently paradoxical rule—which, for my own part, I have followed of late—appears to be justified, viz., that the more localized the primary focus of carcinoma in the breast is, the more wide-reaching should be the excision on the above lines. That is to say, there is in such cases a fair prospect of complete eradication of the disease by a wide-reaching operation, and therefore it is justifiable to run some risk of shock. The converse rule appears also to have much to recommend it, viz., that the more wide-reaching the disease the more clearly should the operator keep mere palliation in view, and by limiting his operation avoid the risk of extreme shock." It seems from the results thus far recorded that the expectancy of life is improving as time goes on. Over 33 per cent. of modern cases live more than three years after the operation, but we can not call these cured, since many of them die from recurrence. Local recurrence is not so common; it has generally been in internal regions. This is another good feature, since local recurrence is most depressing, while internal generalization is often not so much so.

On the Pathology and Therapy of Angina Pectoris. THEODOR SCHOTT.—Schott first reviews the theories of angina pectoris, and says that there is generally a sclerotic change in the aorta in its ascending position at a point where it is not without influence on the spot from which the coronary vessels take their origin. This causes an inadequate nourishment of the muscles of the heart with consequent weakening—the Parry-Stokes theory—and the heart has to act against a contracted arterial system. The suddenness of the paroxysm may be directly attributable to the retardation of the circulation within the coronary vessels. A moderate distension of the cardiac muscle may easily lead to a temporary occlusion of one or more coronary vessels at the seat of an already existing constriction. In other cases a thrombus or an embolus may be the cause. He believes that clinical observations support these views and discusses the therapy of the disease. The actual paroxysms are most efficaciously relieved by the nitrites, but he suggests caution in their use. He has found the application of heat of great value in these cases, but in some cases only narcotics are reliable. Iodid—not of potassium, but of sodium

—is also advised by him. He mentions also the value of hydrotherapy and exercise, although not suited to all cases. Finally he says, "Looking, in conclusion, once more at the actual state of our therapeutic experience, we are brought to the conclusion that the results which we obtain by the application of the above-mentioned more prominent medicaments are to be explained by the lowering of the pressure of the blood and the moderation of the heart's action consequent on it. Differing therefrom are the causes which insure success in the balneological and gymnastic treatment, because it is obtained by the exercise of a tonic influence. By strengthening the heart's muscle, as well as by acting on the cardiac nerves, the distressing symptoms of the angina pectoris are either removed or reduced; in other words, *ex juvantibus*, it is shown that the Parry-Stokes theory is based on a real and solid foundation."

British Medical Journal, September 8.

A Discussion on the Indications for the Intranasal Treatment in Diseases of the Ear.—McBride calls attention to a form of deafness occurring in adults which is gradually increasing. In advanced cases the patient hears better in a noisy place. The tuning fork is well perceived by bone conduction, and tinnitus is common. The drum membrane may be somewhat drawn in or normal, and there are sometimes patches of thickening or dark atrophic areas. There also may be normal membranes or a slight red shade, and occasionally the only abnormality detectable is a slight irregularity in the outline of the malleus. In all these cases there may be a degree of Eustachian obstruction, and sometimes the tube is pervious. Many of the patients say they hear worse when they catch cold. He has been in the habit of examining the anterior and posterior nares of these patients, and has usually found gross nasal lesions. Two types are distinguishable: 1, those in which the anterior and posterior nares are either normal or somewhat anemic, with a very sharp differentiation of parts, but without any swelling or congestion; 2, those in which some congestion of the whole tract, including the Eustachian orifices, exists; possibly, some other nasal abnormalities. He thinks that we can separate the two types, viz., so-called sclerotic, and catarrhal. In the former type operating on the nose may do no harm and will hardly benefit. In the catarrhal form it is better to operate on gross nasal lesions or adenoids if they exist. In certain persons he believes that there is a tendency to catarrh of the upper respiratory tract, involving the middle ear, while in others the ear escapes. In certain doubtful cases he believes that the presence or absence of redness about the Eustachian orifices may be a useful indication as to whether or not an operation on the anterior nares is desirable. A slight obstruction may affect the ear by acting as a focus of irritation or causing diminished air-pressure in the postnasal space.

Baber discusses the diseases of the nasal cavities as bearing on ear trouble and their treatment, and remarks that it is astonishing to what an extent the nasal cavities may be obstructed and hearing be very little affected. The removal of nasal growths, even if small, is indicated in chronic non-suppurative middle-ear diseases.

Dundas Grant summed up his remarks by saying that there is a causal association between nasal obstruction and some forms of disease of the middle ear, especially the moist catarrh; but not the typical sclerotic catarrh. In some cases of nerve deafness good results may follow the improvement in nerve tone produced by removal of nasal obstruction. In operations in the nose all precautions should be taken which diminish the possibility of the occurrence of suppurative inflammation of the middle ear. In doubtful cases nasal operations should be avoided, unless there are other indications apart from the affection of the middle ear.

Others who took part in the discussion were Drs. Scanes Spicer; Herbert Tilley, who stated that in his experience the intranasal operations for removal of obstruction in cases of so-called dry catarrh were almost invariably failures; Drs. Walter Jobson Horne, Patrick Watson Williams, Richard Lake, etc.

A Discussion on the Pathology and Treatment of Toxic Paralysis of the Larynx.—Dr. Watson Williams stated that while the present state of knowledge hardly warrants definite generalization, it seems probable that the majority of cases of toxic laryngeal paralyses have their foundations in peripheral neuritis, a view which has been recently expressed by Semon. This would afford an explanation of the varying localization of the paralysis in different territories supplied by the recurrent laryngeal nerve. Thus, excluding the purely myopathic paralyses, toxic paralyses are due to inflammatory generation of the neuron, that is, in its widest sense, neuritis, and may be conveniently divided into two distinct pathogenic groups: 1. Infective neuritis, commonly occurring in the course of diphtheria and less frequently observed in typhoid fever, typhus fever, scarlatina, morbilli, influenza, rheumatism, tuberculosis, syphilis, cholera and malaria. 2. Toxic neuritis, most frequently due to lead-poisoning, but also reported to have occurred in poisoning by arsenic, copper, antimony, phosphorus, alcohol, atropin and morphin. He noted the different cases of laryngeal paralysis as observed, and remarked that while laryngeal paralysis of toxic origin has been reported as resulting from much the same poisons and infectious diseases known to cause paralysis in other regions, we must accept with caution many of the cases recorded, such as where the condition has not been verified by actual laryngoscopic examinations, or where the history does not definitely point to this one sole cause. The treatment of these laryngeal paralyses may be summed up as follows: 1. The resort to appropriate general treatment of the infective disease when that is the cause of the paralysis; and measures directed to the removal of the poison in the circulation and tissues in the case of organic or metallic poisons. 2. Intralaryngeal applications of the faradic or galvanic current, combined with the internal exhibition of strychnin in considerable doses, either by the mouth, or directly into the affected muscles, when feasible. 3. The relief of dyspnea and threatened asphyxia in cases of bilateral abductor paralysis by intubation or tracheotomy—measures which have frequently been necessary in diphtherial and typhoid laryngeal paralysis.

Bulletin de l' Academie de Medicine (Paris), August 28.

Technique of Tracheotomy. Moure.—With a high incision for tracheotomy there is liable to be difficulty in removing the tube later, as subglottic inflammation and mechanical immobilization of the parts may interfere with the resumption of normal breathing. Moure states that the trouble is due to the high incision, which should never be made on the cricoid cartilage, but always lower down, preferably on the second ring of the trachea. The tube should be removed at the earliest possible moment.

Neuropathic Hemorrhages of the Air-Passages. Lancereaux.—A large number of so-called spontaneous epistaxes have a purely dynamic origin in some vasomotor disturbance. Hemorrhages in the pharynx and bronchi may also occur in adolescents or adults, simulating the hemoptysis of tuberculosis, while in fact the lungs are intact. The subjects are usually persons with a predisposition to gout or rheumatism, and a cerebral hemorrhage may occur later. Lancereaux describes several instances in which a hemorrhoidal or menstrual discharge was substituted by a hemoptysis. The treatment should aim to diminish the tendency to hemorrhage and modify the nervous excitability, which is the true cause, by hydrotherapy and muscular exercise. Absolute repose and opium, ergotin or quinin may be indicated. One of the best means of arresting the attacks is a nauseant emetic, which constricts the vessels of the respiratory passages and rarely fails to produce the desired effect.

Nord Medical (Lille), September 1.

Laryngeal Tuberculosis. Bommier.—Pulmonary tuberculosis is accompanied by laryngeal symptoms in about one-third of all cases. Sulphur baths and the seashore [illegible] a tendency to aggravate the latter. Spraying is [illegible] l and is frequently distressing. The intense rea[illegible] ows surgical intervention or cauterization is [illegible] d by th benefit. Total, absolute repose of the throat is imperative. The patient should change his profession if need be, and communicate exclusively in writing. General measures should be supplemented by the external application of boiling water or iodin and inhalation of the steam from a boiling mixture of 30 grams cinnamon, belladonna and opium in 100 of eucalyptus. In the ulcerative stage, lactic acid is perhaps the best for topical applications, but as they must be energetic and repeated four to eight times a day, it is preferable to have the patient apply di-iodoform himself. This is done by spreading the powder on a paper and auto-insufflating it through a glass tube. The end inserted in the throat is bent, 1 cm. from the end, at an angle of 100 degrees, the other end bent at 145 degrees, 4 cm. from the tip.

Revue Medical (Montreal), August 21.

Reduction of Inverted Uterus. M. T. BRENNAN.—A case is described in detail, showing the advantages of this method in certain conditions. After a median laparotomy, the rigid, constricted cervix was slit on one side, and the internal wall of the uterus grasped with forceps two inches below the incision. Gentle traction was then applied until the forceps had pulled this portion of the wall through the constricting ring. An assistant then held the forceps while a second pair was applied an inch below the first, and this portion was gently pulled out in the same way and given to an assistant to hold while a third forceps was applied. By this means the entire uterus was pulled through the ring and restored to place. If possible, slitting the ring should be avoided, to reduce the danger of infection. The incision should be sutured at once and a stitch taken over each of the small wounds caused by the forceps. In the instance described, the results were all that could be desired. The patient was a primipara, 30 years of age, and the inversion had occurred subsequent to normal delivery.

Semaine Medicale (Paris), September 5.

Rapid Induced Abortion. DOLÉRIS.—No statistics of induced abortion can compare with those of skillful instrumental evacuation of the uterus, preceded by dilation of the cervix, if there is time, and if not, by lateral incision. Doléris asserts that curettement, well done, with a broad, fenestrated, blunt and rounded curette, supplemented by swabbing, is not dangerous; the complete evacuation of the uterus is accomplished in a few minutes; there is no fear of hemorrhage as in more protracted operations; the asepsis can be complete, which can never be the case with digital evacuation. There is little or no pain and no anesthesia is required. Chloroform may be dangerous in the grave conditions which demand prompt, artificial delivery. He cites several instances showing the immediate benefit derived from this rapid abortion, induced and entirely completed in a few minutes by the operator himself, with the speedy recovery of the patient. He sutures the incision in the cervix at once as soon as the curettement and swabbing are completed. When a few hours' delay is possible, he commences by inserting one or two large laminaria tents, preparatory to dilating with Hegar's bougies.

Centralbatt f. Chirurgie (Leipsic), September 8.

Operations Without Contact of the Fingers. KOENIG.—The problem of how to render the hands aseptic is solved by Koenig in one word, "Don't." He has become convinced that all methods of sterilization are unreliable and that the only means to insure absolute asepsis is to avoid direct contact of the tissues with the fingers. With the exception of abdominal surgery, he finds that instruments can take the place of the fingers in nearly all operations. The handles must be made longer than at present, and the number of retractors, etc., multiplied. With practice it becomes easy to work without direct digital contact, and to train the assistants in the same technique. If it is necessary to compress a vessel, for example, the assistant should first wrap his finger in sterile gauze.

Deutsche Medicinische Wochenschrift (Leipsic), September 8.

Diagnosis of Esophageal Stenosis. G. HOLZKNECHT.—One or two grams of subnitrate of bismuth are stirred in 100 grams of water and sipped by the patient. He is then placed in front of the fluorescent screen, the rays passing from the right side of the thorax in front obliquely through to the left side, which allows the esophagus to be examined without overlapping shadows. The bismuth is deposited over the walls of the esophagus when arrested by a stenosis, and outlines the shape of the organ and of the normal portion below the stenosis. The bismuth may be swallowed in a tablet and its course traced, as it is arrested by the stenosis, and then suddenly passes rapidly on. If a few scraps of dry bread are eaten first, the tablet test is still more conclusive. By these means the existence of stenosis can be determined, with its localization, degree and length, without annoying the patient by the application of sounds.

Hematologic Investigations. E. BECKER.—The blood was examined in seven different diseases, including syphilis and lead-poisoning, and the findings are here given in detail, with Becker's conclusions. The information thus derived served to differentiate pneumonia from typhoid fever in several instances by the intense neutrophile leucocytosis. Another case of supposed typhoid fever, in a young man who had been shot in the left thorax a year before, was differentiated by the intense leucocytosis noted, which suggested an abscess in the old wound. Ten days later a tumor became evident below the spleen.

Muenchener Medicinische Wochenschrift, September 1.

Cocainization of the Spinal Cord. A. BIER.—As much as 4 cg. of cocain have been injected into the subarachnoid space by some surgeons, and Bier—the original proposer of the method in Europe—protests with horror against such dosage. He has seen accidents, headaches and vertigo follow the use of less than 5 mg., and warns against ever using more than 15 mg. as the maximum. He also protests against assuming that this method of spinal analgesia is ripe yet for general adoption. He has been engaged during the last year in trying to find some substance less toxic than cocain for injections, and has succeeded for animals, but not yet on man. He hints that he has found a means of rendering cocain injected into the subarachnoid space no more toxic than when used elsewhere, which is in itself a great gain, and puts an end to the by-effects of spinal analgesia. He states that he has also succeeded in extending the action of cocainization until operations on the entire trunk and arms can now be performed with it. He trusts that he has succeeded in evolving a truly practicable method, but does not consider it sufficiently tested as yet for promulgation, which will follow later. [Nicoletti, of Naples, reported at the International Medical Congress that no anatomic alterations of any kind could be discovered in the nervous elements of animals killed after experimental anesthesia with cocainization of the spinal cord. The phenomena noted indicate that the cocain has a first vasoconstrictor and then a vasodilator action, and he attributes its analgesic effect to this property. He found that other vasomotor substances have the same effect as cocain in these conditions, and he was equally successful in obtaining analgesia with quinin, antipyrin and ergotin. Pitesci reported that he had used this method on 125 patients and noted symptoms of slight intoxication in 83 and a serious syncopal condition in a few instances, which persisted for several days and required ether and caffein.—ED.]

Neutral Red Test of Vitality of the Phagocytes. J. PLATO.—Ehrlich's neutral red stain colors albuminous matters taken up in a living cell by phagocytosis, while the cell itself is not stained. The red tint is proportionate in its intensity and duration to the vitality and functional capacity of the cell, of which it proves, therefore, an excellent test. As the phagocyte gradually dies, the reducing property of the cell becomes increased and the red stain of the enclosed particles disappears. The disappearance of the stain can thus be accepted as an indication of the waning vitality of the cell. Living gonococci taken up by guinea-pig leucocytes swelled up and were destroyed at once, confirming the natural immunity of animals to the gonococcus infection, while the cocci remained uninjured in human leucocytes. The various microorganisms stain with different and characteristic tints.

Comparative Anatomy of Adrenals. O. Aichel.—Modern research tends to establish that the suprarenals were formed originally from the primitive kidney, and that the adrenals found in man in the vicinity of the testes, and in the broad ligament in the female, are normal formations developed from the kidney, and able to substitute the suprarenals in case of need. Nothing has been learned, or is likely to be learned from comparative anatomy, in respect to their functions.

Pregnancy and Ovarian Tumor. R. Mond.—Ovarian tumors usually increase in size during pregnancy, and have been known to grow during the puerperium. Judging from published statistics, the best *moment for intervention* as far as the mother is concerned, is from the second to fourth month of gestation, but for the continuation of the pregnancy, between the third and fourth month, ovariotomy is the only rational treatment. Mond had occasion to treat a case seen for the first time when the tumor had attained a weight of fifty-seven pounds. With the tumor, fetus and fluids, the small, slender primipara had been carrying a weight of approximately sixty-nine pounds. She died four days after an apparently successful laparotomy.

Optic Neuritis in Chlorosis Simulating Cerebral Tumor. A. Engelhardt.—A young woman, with pronounced symptoms of cerebral tumor, was observed at intervals during a year, a large part of which was spent in the hospital. At the autopsy the discovery was made that, except for unusual anemia and dryness, the brain was normal. The optic nerves were very much degenerated, and on recalling all the symptoms, the conclusion was evident that the case had been one of chlorosis and secondary optic neuritis. The chlorosis had been vaguely suspected during life, but had been so overshadowed by the assumed brain tumor that treatment had been considered superfluous. The patient probably died of direct inanition, as she had refused all food during the last few weeks and, owing to the completely erroneous diagnosis, no attempt had been made to feed her artificially.

Wiener Klinische Rundschau, September 2.

Influence of Adenoids on Morbidity. A. Goldschmidt.—The writer has been making a study of the various affections that have been cured as the result of removal of adenoid vegetations. Besides countless cases of deafness, throat and ear affections, he has found a number of instances of the cure of hay-fever, idiocy, intense stuttering, recurring headaches, aprosexia or inability to concentrate the attention, and has himself observed a severe case of chorea rapidly subside after the vegetations had been ablated. Dobberke also cured a case of epilepsy in a patient 19 years old, who had had no recurrence at the date of his communication. Enuresis is frequently noticed in connection with the vegetations, has been cured by their removal in about half the cases on record, and improved in most of the rest. The difficulty in breathing and coughing enhances materially the tendency to hernia. Lauffs has reported the retrogression of a prolapsed anus consecutive to ablation of the vegetations in the throat. The disturbance from them has in some cases simulated a meningitis or psychic deafness, and the removal has in others been followed by a return to normal of retarded development. Hemophilia, anomalies in the arteries, and acute phlegmasia of the upper air-passages contraindicate operation.

Grafts of Skin from a Chicken. D. DeFrancesco.—An explosion had produced a deep defect in the leg of a young man, which Francesco lined with small scraps of skin taken from the side of the breast under the wing of a spring chicken. The grafts included the derma and epidermis, and nearly all healed in place. The defect was completely lined with this skin in three sittings. It retained its specific vitality for a while, evidenced by the production of one small atrophied feather, but soon healed into apparently normal human skin.

Suture of the Liver. G. S. Segale.—The method described aims to supply a mechanical support for the threads on each side of the wound in the liver tissue. Six to a dozen long, ebonite or ivory beads are threaded on catgut. Each bead is slightly pointed at one end, which fits into the hole in the next bead. They thus form a comparatively solid bar when fitted close together. One of these bars is applied on each side of the wound, and a long stitch taken through the parenchyma embraces the bar on each side. The ends of the thread forming the loop-stitch are tied over one of the bars. As many of these stitches are inserted as may be required. The bars of beads hold them firm until the catgut is absorbed, when the beads separate and soon become encapsulated. Extensive tests on large animals have established the harmlessness of the method, the complete surgical success, the perfect restoration of function and the rapid encapsulation of the relics of the suture-material.

Brazil Medico (Rio Janeiro), August 15.

Neurasthenia and Tuberculosis. Guimaraes.—Tuberculosis as an etiologic factor in neurasthenia has not been awarded the attention it deserves. Guimaraes describes some personal cases that confirm this view, and states that there is a heredo-tubercular neurasthenia, similar to that already established for syphilis.

Klinitchesky Journal (Moscow), June and July.

Mechanical Treatment of Cardiac Dropsy. S. I. Schwartz.—The toxic substances contained in the ascitic fluid are taken up into the organism when absorption follows the use of medicinal measures for the cure of ascites or cardiac origin. The sudden removal of the entire amount may also be the cause of sudden death in these cases. For these and other reasons Schwartz urgently advocates the general adoption of Fürbringer's simple and effective drainage with a fenestrated rubber tube, which gradually removes the fluid without taxing the heart or organs in any way. He adds that immobilization is indicated, supplemented by other measures, to reduce the task of the heart as much as possible. If it is impossible for the patient to recline, as much of the body as possible should be supported.

July.

Multiple Cutaneous Sarcomatosis. V. V. Ivanoff.—A patient was received at Pavloff's clinic with evidences of severe infection complicating or complicated by multiple cutaneous sarcomatosis, first noticed two months previously. Death ensued in fifteen days. The acute, tempestuous course of the affection in the second period may have been due to the rapid generalization of the sarcomatous tumors, or to some unknown influence exerted by the sarcomatous process. They all proved to be typical round-celled sarcomata, with extensive mitosis. Ivanoff is convinced that the skin was secondarily affected, although the cutaneous manifestations then assumed the predominance. Possibly the skin—as the point of least resistance—vicariously substituted some other organ, the kidneys, for instance. The patient had suffered from nephritis during her last pregnancy. The tumors invariably commenced in the reticular layer of the corium. No micro-organisms could be cultivated from the blood during life, nor from infarcts in the kidneys, spleen or lungs after death.

Treatment of Aneurysms With Gelatin. L. E. Golubinine.—There have been fifty-six cases of aneurysm treated by Lancereaux's method of subcutaneous injections of a gelatinized solution, according to the published reports. The most favorable results were attained by Geraldini, whose five cases were all improved, and by Stoicesco, who had only one failure in six cases. In this article, all the cases on record are tabulated, including Futcher's nine, in only one of which there was improvement. The author himself has been even less fortunate, as he could not discern any improvement in his eight cases. Nevertheless he is strongly convinced that the method deserves more general application, as even the twenty cases on record in which improvement has been noted constitute a proportion of 35 per cent. out of the total of fifty-six, and this is certainly encouraging. There was subjective improvement in a number even when they were not objectively benefited; the distress and pain ceased in a number of instances. He urges further study of the method and of the action of gelatin on the circulation, both in health and disease.

Revista Medica (Mexico), September 1.

Paroxysmal Tachycardia Due to Tenia. E. F. MONTANO.—The patient in the case described was affected periodically with intense dyspnea, distress, and pulse 112. Aortic insufficiency had been diagnosed, but digitalis only aggravated the symptoms, which were finally traced to reflex action from the presence of a tenia.

Nordiskt Medicinskt Arkiv (Stockholm), August 9.

Apparatus for Thorough Sterilization of Milk. I. JUNDELL.—That tubercle bacilli are not killed by the usual methods of sterilizing milk in creameries has been demonstrated by the discovery of living bacilli in market butter made according to the most approved modern methods. Jundell ascribes this failure in thorough sterilization to the fact that the bacilli are not exposed long enough to the high temperature required to destroy them all. He has invented a contrivance to supplement the ordinary apparatus, which, by retarding the circulation of the milk through it, enables the action of the heat to be prolonged and accomplishes the desired end without injury to the milk. It consists of a cylinder fitted with a number of alternating horizontal discs nearly filling the lumen. The milk thus follows a zigzag course through it. Tests with animals inoculated with milk infected with enormous quantities of bacilli and then sterilized in this manner, showed that not one of the bacilli had remained alive. Jundell uses it with the "G. Salenius radiator," which enables the butter to be made at once from the cream without further delay or manipulation.

Localization of the Motor Oculi Nucleus. G. AHLSTROM.—Examination of the brain of a man who had had his left eye enucleated several years before his death—the right eye being normal—showed that all the corresponding nuclei were intact except the left one of the median pair of small-celled nuclei which, with all its medullary fibers, was completely atrophied.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Sept. 5 to 12, 1900, inclusive:

Edward T. Comegys, major and surgeon, U. S. A., previous orders directing him to act as medical supply officer at Nagasaki, Japan, amended so as to direct him to establish a medical supply depot at Taku, China.

Charles H. Fischer, acting asst.-surgeon, leave of absence extended.

Deane C. Howard, captain and asst.-surgeon, U. S. A., member of a board convened at Fort Hancock, N. J., to devise plans for the extension of the water-supply and for the disposal of liquid excreta at that post.

George Newlove, acting asst.-surgeon, from Fort Leavenworth, Kan., to Newcastle, Del., for annulment of contract.

John L. Phillips, captain and asst-surgeon, U. S. A., from Fort Columbus, N. Y., to accompany recruits on the transport *Buford* to Manila, P. I., and for subsequent duty in the Division of the Philippines.

Jefferson D. Poindexter, captain and asst.-surgeon, U. S. A., to accompany the command that may be detached from Fort Reno, O. T., to make a test of the emergency ration.

Merton A. Probert, acting asst.-surgeon, from temporary duty at Columbus Barracks, Ohio, to San Francisco, Cal., to accompany troops to the Philippine Islands.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy for the week ending Sept. 15, 1900:

Asst.-Surgeon C. A. Crawford, detached from the *Eagle* and ordered to the *Dixie*.

Surgeon M. F. Gates, detached from the naval hospital, Norfolk, Va., Sept. 12, and ordered to the *Atlanta*, Sept. 15.

P. A. Surgeon A. M. D. McCormick, ordered to the naval hospital Norfolk, Va., for duty, when detached from the *Montgomery*.

P. A. Surgeon L. Morris, detached from the *Baltimore*, when put out of commission, and ordered home and to wait orders.

Pharmacist J. Pearson, detached from the *Wheeling*, and ordered home and to wait orders.

Asst.-Surgeon W. E. G. High, detached from the naval hospital, Yokohama, and ordered to the *Oregon*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ending Sept. 13, 1900:

Surgeon Preston H. Bailhache, granted leave of absence for nine days from Sept. 14.

Surgeon Fairfax Irwin, to proceed to Boston quarantine for special temporary duty.

Surgeon W. P. McIntosh, to proceed to Biloxi and Ship Island for special temporary duty.

Surgeon J. J. Kinyoun, to proceed to Victoria, Port Townsend and Astoria Quarantine, for special temporary duty.

P. A. Surgeon C. P. Wertenbaker, to proceed to Galveston, Texas, for special temporary duty.

P. A. Surgeon B. W. Brown, granted leave of absence for two months, from Nov. 1.

Asst.-Surgeon J. F. Anderson, to proceed to Liverpool, England, for special temporary duty.

Asst.-Surgeon Edward Francis, relieved from duty at New York City (Stapleton), and directed to proceed to the immigration station and report to Surgeon L. L. Williams for duty.

Asst.-Surgeon L. P. H. Bahrenburg, relieved from duty at the immigration station, and directed to proceed to Liverpool, England, reporting to Asst.-Surgeon J. F. Anderson at U. S. Consulate for duty.

Acting Asst.-Surgeon R. E. L. Buford, granted leave of absence for one month from November 3.

Acting Asst.-Surgeon S. Gomez, granted extension of leave of absence for ten days from Sept. 19.

Acting Asst.-Surgeon J. A., Moncure, directed to proceed to Brunswick quarantine, and assume temporary charge of station for thirty days from Nov. 3.

Sanitary Inspector Lea Hume, to proceed to Galveston, Texas, and report to Surgeon Peckham for special temporary duty.

Hospital Steward S. W. Richardson, granted leave of absence for twenty days from Oct. 1.

Hospital Steward G. C. Allen, relieved from duty at Delaware Breakwater, and directed to proceed to Mullet Key Detention Camp and report to medical officer in command for duty and assignment to quarters.

Hospital Steward E. T. Olson, relieved from duty at Mullet Key Detention Camp, and directed to proceed to Washington, D. C., and report to Bureau for duty.

APPOINTMENT.

Malcolm McKay reinstated and appointed senior hospital steward.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Sept. 15, 1900:

SMALLPOX—UNITED STATES.

Alaska: Cape Nome, Aug. 18, 3 cases.

Colorado: Jefferson County, Aug. 28-Sept. 1, 11 cases; Las Animas, Aug. 28-Sept. 1, 1 case.

Kansas: Wichita, Sept. 1-8, 1 case.

Louisiana: New Orleans, Sept. 1-8, 2 cases.

Minnesota: Minneapolis, Sept. 1-8, 1 case; Winona, Aug. 28-Sept. 4, 3 cases.

Ohio: Cleveland, Sept. 1-8, 2 cases; Dayton, Sept. 1-8, 1 case.

Texas: Eagle Pass, in Mexican portion of town, Sept. 7, 1 case.

Utah: Ogden, Aug. 1-31, 2 cases; Salt Lake City, Sept. 1-8, 1 case.

West Virginia: Wheeling, Sept. 1-8, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, Aug. 18-25, 2 cases.

Belgium: Antwerp, Aug. 18-25, 1 case.

Brazil: Rio de Janeiro, July 13-30, 38 cases, 10 deaths.

England: Liverpool, Aug. 18-25, 6 cases; London, Aug. 18-25, 1 case.

India: Bombay, Aug. 1-14, 6 deaths; Calcutta, Aug. 4-11, 7 deaths; Karachi, Aug. 5-12, 1 case, 1 death.

Mexico: City of Mexico, Aug. 26-Sept. 2, 4 cases, 5 deaths.

Russia: Moscow, Aug. 11-18, 6 cases; Odessa, Aug. 18-25, 1 case; St. Petersburg, Aug. 11-25, 96 cases, 11 deaths; Warsaw, Aug. 11-18, 10 deaths.

Switzerland: Zurich, Aug. 11-18, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, July 13-20, 10 deaths.

Colombia: Barranquilla, Aug. 19-26, 1 death; Panama, Aug. 27-Sept. 1, 3 cases, 1 death.

Cuba: Cienfuegos, Sept. 8, 1 case; Havana, Aug. 2-Sept. 1, 249 cases, 23 deaths.

CHOLERA.

India: Bombay, Aug. 1-14, 695 deaths; Calcutta, Aug. 4-11, 35 deaths.

PLAGUE.

India: Bombay, Aug. 1-14, 105 deaths; Calcutta, Aug. 4-11, 52 deaths.

Philippines: Cebu, July 14-21, 1 case; Manila, July 14-21, 4 cases.

Turkey: Constantinople, on S. S. *Niger*, from coast of Asia Minor, Aug. 27, 1 case.

Original Articles.

ASEPTIC MINOR GYNECOLOGY.

WITH DEMONSTRATIONS.*

AUGUSTIN H. GOELET, M.D.

Professor of Gynecology in the New York School of Clinical Medicine, etc.

NEW YORK CITY.

It is my purpose to submit to my colleagues, both in gynecological and general practice, some of the fruits of my observations and to suggest some improvements in technique, the outcome of personal experience, which will, I hope, prove useful. Progressive men are ever ready to improve their methods, hence suggestions are always acceptable. We may all learn something from each other; some detail that one may lose sight of may be suggested by another's methods. The general practitioner often does excellent work in our line, and we may gain some points from him. I shall hope, therefore, to have a full discussion of the subject from that side of the house also.

It is easy enough to be clean in every-day gynecological work. It is either a matter of taste or habit. Yet, you know very well, cleanliness is one of those good habits for which some never acquire a taste. One who is clean as a matter of taste is more to be trusted than one who is obliged to acquire it as a habit. Like all good habits, it is hard to acquire, and is then seldom proficient. To be strictly surgically clean, one must be naturally so inclined. An acquired habit is not often unfailing unless, perhaps, it is a bad habit.

Would you permit a man with habitually dirty finger-nails, or who is careless about his linen, to examine a member of your own family? I should not, if he was the most distinguished gynecologist in the land. If it was unavoidable, I should want him to wear rubber gloves, though he washed his hands, and I should want to furnish the gloves, fearing, if he used his own, he would bring them wrapped in his handkerchief.

Nowhere is cleanliness more important than in every-day gynecological work, both for the protection of the patient and the physician himself. Patients have been infected not infrequently by a failure of proper aseptic precaution, as we all know. Physicians themselves have been infected while examining patients, when they have not taken proper precautions. The genito-urinary specialist runs less risk than the gynecologist, because the necessity for precaution is constantly before him to suggest it. Let not the physician think he will offend his patient by methods to attain asepsis in simple gynecological examinations. On the contrary, it pleases her to see that she is taking no risk of contamination because the physician is taking none himself.

As evidence of the imperfect attempt at asepsis in some instances, I will cite one or two incidents. I have seen men prepare for abdominal operations, and after scrubbing and disinfecting their hands, run their hand down in their pocket, pull out a pen-knife and clean the finger-nails, then put on a sterile gown and proceed to operate. With these men cleanliness is not a matter of taste. An attempt has been made to acquire it. I know men who make a great fuss about asepsis and in their preparation for an operation they remind you very much of a slow horse that is making a great effort to get over the ground, and the casual observer would think he was making good time, but really he is slow, very slow. Such men are dirty, really very dirty. I have often overheard nurses criticise their methods because they could see that with all their fussing they failed in asepsis.

The importance of cleanliness in every-day gynecological work can not be over-estimated. It always reverts to the benefit of the physician, as well as to the patient, and inspires confidence. If the patient sees that her attendant is particular for himself as well as for her, she may feel safe. Those who are themselves clean and particular will certainly be favorably impressed, and those who are not may profit by it as a suggestion. It is just as easy to be clean in routine office-work, and it requires no more energy than to be unclean. Everything should be done in an orderly and methodical manner and everything about should bear the mark of precision. Careless, slipshod and untidy methods actually consume more time, because details are not carried out in their proper order; many require repetition, and one may interfere with the other.

Arrangement of the Examining Table.—The examining table should be arranged ready for use, with a fresh, clean, white cover, and pillow with clean case. A fresh, clean napkin should be spread over the pillow for every patient. This should be removed and replaced by a fresh one in her presence after she leaves the table. A clean sheet, neatly folded, should be in readiness to cover the patient. At the foot of the table there should be placed a clinical air-cushion, which I show you. It has the following advantages. It is only twelve inches deep, which permits it to be used on the table for office examination, when the patient's clothing is not loosened about the waist, since the cross-bar of the air-cushion is below the waist line, when it is adjusted in proper position. The downward curve of the cross-bar is useful for the same reason. It is only fifteen inches across the widest part, so that the buttocks rest on, instead of between, the arms of the cushion. The stiffening between the lower ends of the lateral arms of the cushion prevent it and the flap from becoming wrinkled up. The strap is to fasten it in position on the table so that it will not slip around, or it may be utilized for strapping the cushion to the patient for operative work.

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

This pad is used to protect the table and the clothing of the patient from getting wet. Over this may be spread for each patient a fresh square of white rubber sheeting. After being used, these squares are washed and sterilized.

Arrangement of Instruments required on Side-Table, with Absorbent Cotton, Gauze, Tampons, etc.—The instruments needed should be selected from their cases, where they are kept when not in use, and placed in a flat pan and covered with some antiseptic solution that will not injure or tarnish them. This should be done beforehand and the dish covered with a clean towel to conceal them from view, since some nervous patients have a dread of instruments. All instruments should be kept brightly polished and should be replated when they begin to show wear. This can now be done at so little cost that no one need neglect this little item. The aphorism that a workman is known by his tools is quite true, and should be borne in mind. The tray or dish containing the instruments should be placed on a low table conveniently to the right of the physician as he faces the foot of the table. All things likely to be needed for the examination, as sterile absorbent cotton wads for sponging, gauze and cotton prepared for tampons with strings attached, or prepared wool for same, are placed in separate glass jars with covers, on a lower shelf on the same table holding the instruments. On the same shelf should be placed such remedies as may be needed, such as glycerin, iodin, and a solution of iodin in glycerin, 1 part to 32, which is to be preferred to other mixtures with glycerin, as boroglycerin or ichthyol and glycerin. This should be placed conveniently at hand before beginning the examination or treatment of the patient.

Under this table should be placed a deep receptacle—a deep cuspidor, for instance—for depositing waste cotton wads after they have been used. This receptacle should be deep and have a rather contracted mouth or neck, so as to conceal from view what is thrown into it.

Reservoir and Irrigating Apparatus.—A reservoir containing an antiseptic solution for irrigation should be placed conveniently upon a door-frame or window-frame, and should be arranged on a slide, with pulley for raising and lowering for convenience in refilling and to get the required elevation. This reservoir, for office work, where it can be permanent, is constructed preferably of a large glass percolator, of two-quart capacity, with rubber tubing, eight or nine feet long, attached. This tubing should have a large caliber, so as to convey a stream of considerable volume. The necessity for a wide-mouth reservoir, such as a percolator, is that it may be more readily washed inside.

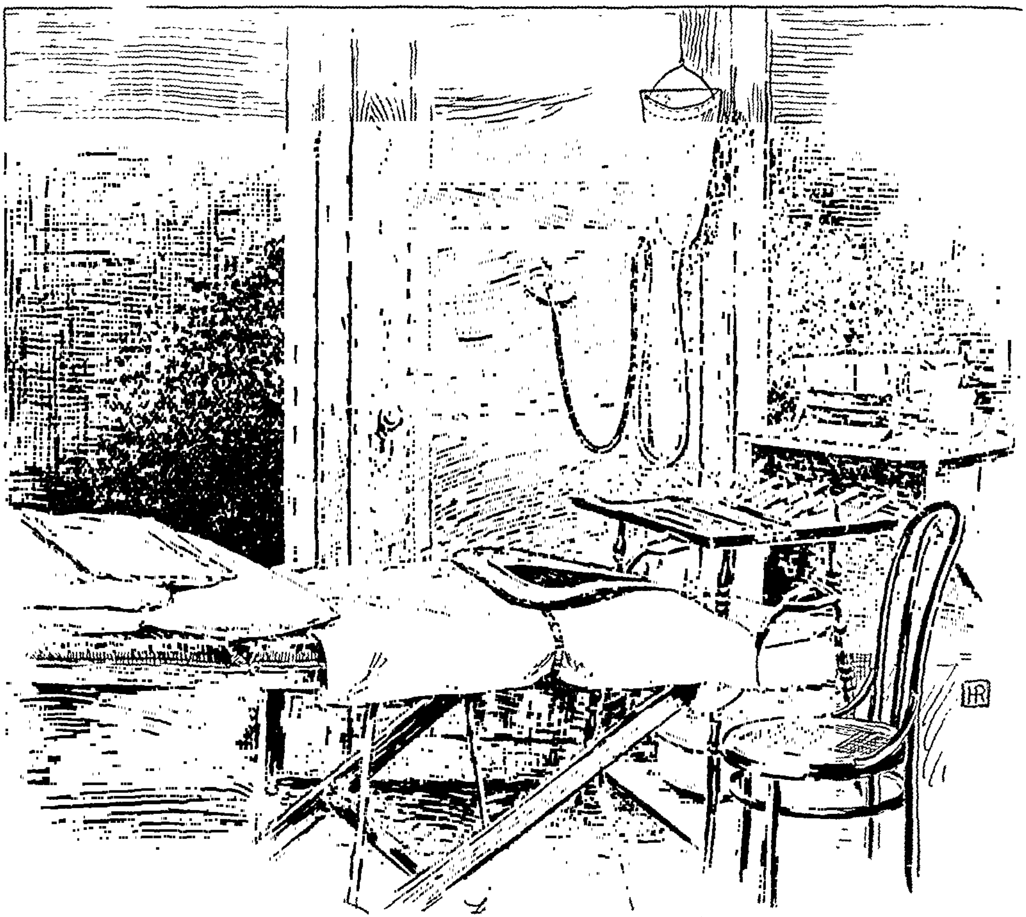

Fig. 1.—Interior of physician's office arranged for aseptic gynecological work.

Necessity for Washing and Sterilizing the Hands.—While the patient is being placed on the table by the nurse the physician washes his hands, for no examination should be made with unclean hands. If he is not so fortunate as to have a nurse to assist him, he places the patient in position on the table first and washes his hands afterward. This is essential, as the hands will become soiled in handling the clothing or shoes, which he may be obliged to touch in getting the feet into right position.

The necessity for sterilizing the hands before making a vaginal examination can be appreciated if the fact is recalled that infecting germs exist on the hands of every individual under ordinary conditions and even after ordinary washing. The staphylococcus is always present, as shown by actual bacteriological tests, and very often the streptococcus also. A suggestion as to the method of washing the hands may, therefore, not be amiss. It is well known that ordinary soap does not clean the hands, nor does ordinary washing. Scrubbing with a stiff brush and a reliable antiseptic liquid soap is essential. I have employed for this purpose, with much satisfaction, a liquid soap—synol. It does not roughen or injure the hands, but, on the contrary, makes them soft. This soap should be kept in a receptacle over the basin, preferably of glass, with a contrivance that will permit the necessary amount to escape into the hands by pressing a button attached to a lever. Thus, there is no chance of contamination of the whole when a small quantity is needed. The soap should be well rubbed into the hands and around the fingers and nails, by rubbing them together, then it is washed off by a stream of warm water from the faucet, then with more soap and a nail-brush, the hands, fingers and nails are scrubbed thoroughly. Before the scrubbing is finished the nails should be cleaned, preferably with a flat, dull-pointed stick. Then they are again scrubbed, and finally the soap is rinsed off under a stream of warm water. The stream is preferably regulated by foot pressure which controls both the hot and cold water, so as to avoid touching the handles of the faucet in turning it on. I have found, by actual bacteriological tests, that this will positively destroy both the streptococcus and staphylococcus on the hands with five minutes' scrubbing.

Method of Placing the Patient on the Table.—The manner of placing the patient on the table is important. She should be directed to place her back to the foot of the table, and while the nurse or physician stands in front of her holding the sheet spread out between them, so as to conceal her movements perfectly, she is directed to pull up her skirts well behind and sit back on the edge of the table with the skirts free above it. Then she lies back on the table, the sheet is thrown over her, covering her completely, and the feet are lifted into position upon the steps, which should project beyond the foot of the table some seven or eight inches, so that the buttocks may come to the edge of the table. The rubber cushion being in position on the table, the buttocks are now resting on this. Either she or the nurse now draws aside the drawers, which are usually split up the back, thus getting them out of the way, outside of the inflated rim of the air-cushion on each side. The bare buttocks are therefore resting on the cushion, and there is no risk of wetting the clothing.

Antiseptic Irrigation of the Vagina.—Unless inspection of the vagina is necessary, before making a digital examination, or unless it is necessary to take specimens of vaginal secretions for microscopic examination, the nurse should now proceed to irrigate the vagina and vulva with an antiseptic solution. If there is no nurse present, this, though very embarrassing to both, must be done by the physician. I wish to say a word as to the method of irrigating the vagina to secure cleanliness. The usual method is most ineffectual. To do it perfectly it is necessary to distend the vagina and its folds and to permit the solution to escape with a gush. In order to accomplish this readily I have had made a vaginal irrigator with shield. It consists of a hard rubber or glass nozzle, with slits in the end instead of holes, so as to permit the solution to escape more rapidly. This vaginal nozzle is inserted through the opening in the shield, to the back of which is attached the tubing from the reservoir. This shield has a concave surface three inches wide by five inches long, which fits the vulva. It is covered with soft rubber with a raised rim around the circumference. The vaginal nozzle is inserted and the shield pressed up against the vulva snugly. The water from the reservoir is permitted to flow into the vagina until it becomes distended, then the shield is withdrawn a short distance and the water is permitted to escape with a rush. This maneuver is to be repeated until the reservoir is exhausted. The shield serves the double purpose of compressing the vulva and preventing the escape of the solution so as to distend the vagina, and at the same time protects the hand holding it from contact with the escaping solution. This is the only absolutely reliable method of cleansing the vagina. Each shield is furnished with two of the soft-rubber covers, so that one may be in use while the other is being sterilized.

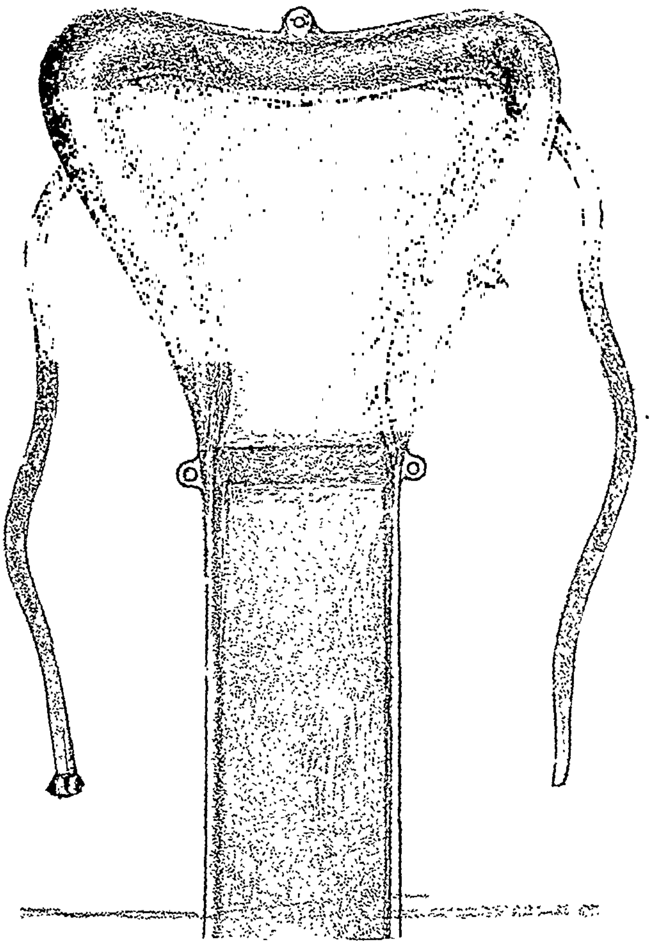

Fig. 2.—Clinical air-cushion for office table or operating table.

The antiseptic employed for this irrigation should be one that is effective without being irritating. I prefer a 1 per cent. solution of the antiseptic soap which I employ for washing the hands, and have found it most satisfactory, on account of its soapy character, in removing the secretion that sometimes adheres quite tenaciously to the vaginal walls and its folds.

Lubricant for Finger and Speculum.—The lubricant employed for the examining finger and instruments is most important, both from the standpoint of cleanliness and comfort of the patient, as well as for the physician. I have abandoned all forms of grease, because they adhere to the parts and are not easily removed, and because they can not be removed from the hand without hard washing and scrubbing. The soap used [illegible] washing the hands I [illegible] convenient [illegible] agreeable. It is easi [illegible] hand by ply placing it under a stream of water. It is removed from the vulva by wiping with a damp cloth or absorbent cotton. The same lubricant is used for the speculum. Besides being convenient, it possesses the additional advantage of being antiseptic.

Method of Making Digital Examination of the Vagina.—If a suspicious vaginal discharge is encountered, however, it is wiser to employ rubber gloves or rubber finger cots, when a digital examination of such cases is required. A digital examination should be made with one finger, since just as much can be felt by employing one properly, and it will reach just as far, if the knuckles are not doubled up. The outside fingers should be straightened out and made to slip between the folds of the buttocks. In this manner the reach of the index finger is much increased. The insertion of two fingers into the vagina, besides being unnecessary, is most unpleasant, and even disagreeable, to the patient. Both hands should be used alternately for palpating the appendages, since the palmar face of the finger-end is more acutely sensitive and the touch is more reliable when the finger and hand are straight, than when bent over awkwardly to palpate the opposite appendage. Therefore the index finger of each hand should be educated, and a physician should be able to palpate equally well with either.

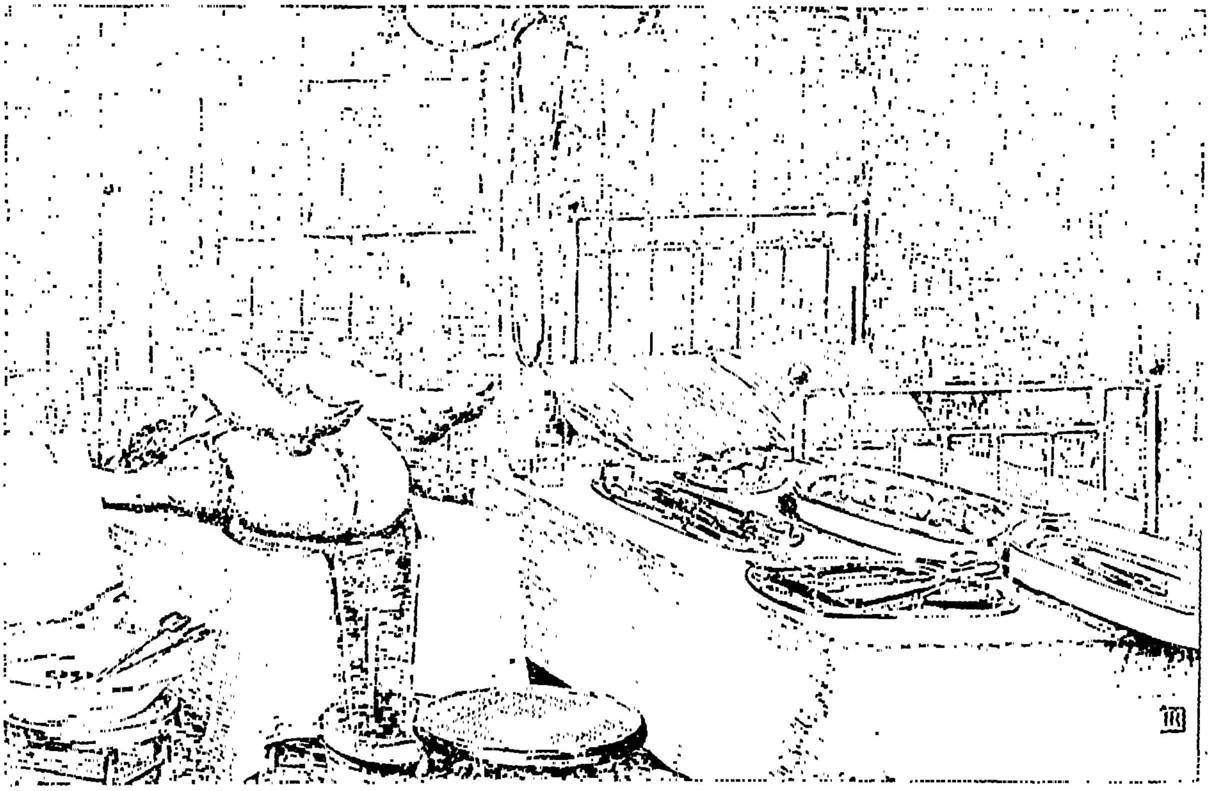

Fig. 3.—Emergency case in connection with operation in private house.

Method of taking Specimens of Secretion for Microscopical Examination.—When it becomes necessary to take specimens of vaginal secretion for microscopical examination, which is most important, since we should know the character and significance of every discharge that is encountered in this line of work, though it is often neglected, a sterile speculum is inserted into the vagina, preferably a simple perineal retractor. This is lubricated on the outer side and inserted deeply into the vagina, the end of the beak passing into the cul-de-sac behind the cervix. A loop of platinum wire fastened in a glass handle is sterilized by passing it slowly several times through the flame of an alcohol lamp or Bunsen burner. With this a specimen is taken from the urethra by inserting it within the meatus and turning it around or gently pressing it against the sides. Another similar sterile platinum loop is selected and another specimen taken from the vaginal wall or side of the cervix at the cervico-vaginal fold. Still another is inserted well into the cervix after the visible secretion at the external os has been wiped away with a pledget of sterile absorbent cotton in the grasp of a dressing forceps. As each specimen is taken, it is deposited on a clean cover-glass and teased out into a thin film with the platinum loop. Then it is placed under a bell glass to dry. When dry it is fixed on the cover-glass by passing the reverse side quickly through an alcohol flame or Bunsen burner twice. I will not go into the details of staining and mounting these specimens, as it is understood by most of you, and those not familiar with it can readily find it described elsewhere.

Uterine Irrigation.—Besides irrigation of the vagina, which is done solely for the purpose of securing cleanliness, and seldom by the physician as a therapeutic measure, irrigation of the uterine cavity is frequently necessary, both for the purpose of securing cleanliness and drainage of the cavity, and also for therapeutic purposes. For this purpose I employ a clinical double-current irrigator. It is small enough to be inserted through the cervical canal in most instances where irrigation is required. In conditions requiring irrigation, the canal is usually larger than normal, though it is not invariably so. Where it does not enter readily, a piece of rubber tubing may be slipped over the outside, insulating it to within two and a half to three inches of the end, and converting it into an electrode temporarily, there being an attachment at the outer extremity for connection with the cord from the battery. By using this connected with the negative pole of the galvanic battery for a few moments with a moderate strength of current (10 M.), it will slip by the constriction. Where there is much constriction in the canal, it is best to continue the current during the entire irrigation, which will facilitate subsequent drainage by relaxing the canal.

There is considerable advantage in having the outer tube or canula as long as it is in this instrument, because it conducts the outflow outside of the vulvar orifice, where it may be emptied into a basin held under it. The outer tube broadens from a point two and a half inches from the point to the exit, which obviates blocking of its caliber. The inner tube, which conducts the in-flow, terminates at the point of the instrument, and the opening is a lateral split similar to a gas-tip. This is for the purpose of projecting the liquid from the point of the irrigator tube, and the split is to permit it to escape laterally if the end impinges against the fundus.

I have found that irrigation of the uterus is the most satisfactory method of treatment for endometritis, both where curettage is necessary and when it is not. After curettage it is particularly useful to remove debris, clots and secretion, which will collect in the cavity and prove a source of irritation if not removed. When medication of the surface is necessary, it is certainly the most satisfactory and least objectionable method of making an application, since an application thus made is most thorough to the whole surface and none of the solution is left behind in the cavity to provoke irritation.

Cleansing of Instruments.—After instruments have been used, either for operative work or for simple examination of the female genitalia, they should be thoroughly cleansed and sterilized before being used again. They should be placed immediately in a 2 per cent. solution of the antiseptic soap, where they are allowed to remain for five minutes. They are taken out of the solution and scrubbed with a stiff brush if they have come in contact with blood or pus, particularly the parts where there are serrations and about the locks. Double-bladed instruments, such as forceps, dilators and scissors, should be taken apart and all parts thoroughly washed. Scissors blades and scalpels are dipped into the soap full strength and wiped off thoroughly with a bit of gauze. When instruments are tarnished, they should be scrubbed with the finest grade of sapolio on a bit of gauze. When this does not brighten the surface or remove roughness, they should be repolished or replated. After the instruments have been carefully washed in this manner, they are placed in a sterilizer partially filled with a 1 per cent. solution of the synol soap and are boiled for three minutes. They are then laid away in a case on glass shelves. Cutting instruments, scissors and knives are not boiled with the other instruments, but are immersed in a boiling solution of the soap separately for two minutes.

In office work, a sterilizer may be kept boiling in a convenient place and the instruments may be placed in it each time after they have been used, but they should be first washed.

When instruments are required for immediate use and time can not be spared for sterilization by boiling, they may be quickly sterilized by placing them in a pan and pouring over them a small quantity of alcohol, which is then ignited. After the alcohol has been permitted to burn for half a minute, if there is too much alcohol to burn out in that time, water is poured over them from a pitcher and the flame is extinguished. Burning alcohol is a very hot flame, and the temper of instruments would be destroyed if submitted to it for too long a time, hence it is not well to let it burn for more than half a minute.

When not in use, instruments should be kept in a closed case, free from dust, on glass shelves. They should be cleansed and sterilized before they are put away as described above, and if one should be taken out and handled it should be sterilized before it is put back into its place; thus instruments are kept always ready for use. It is wiser, however, to boil them for two minutes again immediately before they are used, because dust may settle upon them from the opening of the doors of the case containing them.

Asepsis in Examination at the Patient's Home.—Asepsis is quite as important when patients are examined or treated at their homes. If the physician will go prepared for it, it is as readily attained here as elsewhere. Everything that may be needed to secure perfect asepsis should be taken with him in his bag, including antiseptic liquid soap, sterile absorbent cotton, gauze, sterile nail brush, etc.

The average practitioner does not, perhaps, possess the necessary gynecological instruments that may be needed in cases which he may be compelled to treat, and, as a rule, his outfit is exceedingly meager. If he knew just what he would want, he would, undoubtedly, possess himself of them. Recognizing this, I have suggested to Messrs. Knauth Bros. to make up this aseptic gynecological emergency case with instruments. I have endeavored to select those instruments most essential and to omit those that are superfluous in order to economize space and weight.

Aseptic Gynecological Emergency Case with Instruments.—The case consists of two aseptic white enameled oblong or square basins which fit together, forming a bottom and top, and the instruments are compactly arranged on three metal trays, which may be lifted out without touching the instruments. These basins are to be used as aseptic trays to hold instruments during an operation or examination. Being already clean, it is only necessary to take from the trays such instruments as will be required and place them in one of the basins and cover them with an antiseptic solution. Then proceed with the work in hand.

GYNECOLOGICAL EMERGENCY CASE.

First or upper tray contains: 5 curettes, one sharp and four dull, of different sizes; 2 uterine irrigators, one, the larger, for use in operations, and one smaller clinical irrigator for use in office.

Second or middle tray contains: 1 uterine dilator, 1 needle forceps, 1 angular tenaculum forceps, 1 combined uterus dressing forceps and placental forceps, 1 uterine packing forceps.

Third or bottom tray contains: 1 long-handled, sharp-pointed, curved scissors, 2 broad-ligament clamps, 1 vaginal speculum, 1 scalpel, 1 tenaculum, 1 shaving knife, 1 metal case of one dozen assorted needles, 1 metal box for dusting powder, 1 glass receptacle for liquid antiseptic soap, 1 glass receptacle for absorbent cotton, 1 glass receptacle for absorbent gauze, 1 sealed tube of assorted ligatures containing chromic and plain catgut and silk.

The outer leather case holds, besides the instrument case, a clinical air-cushion, a portable rubber reservoir with tubing (9 feet) and with vaginal irrigating nozzle and vulva shield, and a simple leg-holder strap.

On the first tray there are two double-current irrigators; one, the larger, for use during operation after the cervical canal has been dilated; the smaller, f[illegible] clinical work without previous dilatatic [illegible] ca[illegible]

This case is placed, for con[illegible]

in a leather outside case with [illegible] been space allowed for packing away a three-quart rubber reservoir with pulley attached and tubing, vulva shield and vaginal nozzle and also a clinical air-cushion and leg-holder.

This irrigating apparatus can be placed high against the door-frame or window-frame, as a hook with screw accompanies it. There is also attached a pulley for raising and lowering it for convenience in filling and to obtain readily the required height for the work in hand. The rubber reservoir is made with wide mouth to permit the inside to be washed out. It can be rolled up with shield and tubing complete so as to occupy a very small space. The rubber air-cushion can also be rolled up in a small package, small enough even to be carried in the pocket.

With a case of this kind complete, the practitioner who is compelled frequently to ride long distances in the country will be able to cope with any ordinary gynecological case that he may unexpectedly encounter.

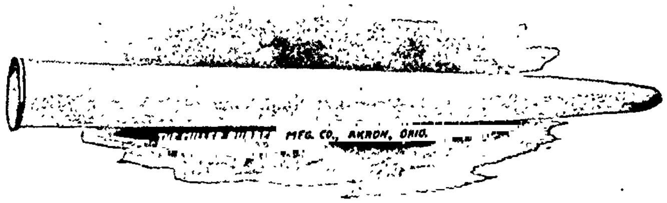

Fig. 4.—Aseptic rubber cover for sponge or laminaria tent.

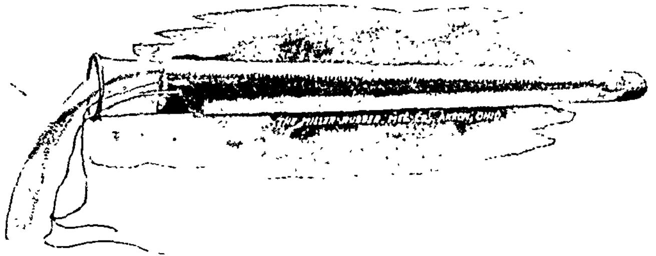

Fig. 5.—Aseptic tent cover, showing tent inserted with gauze around it ready for insertion into the canal of the cervix.

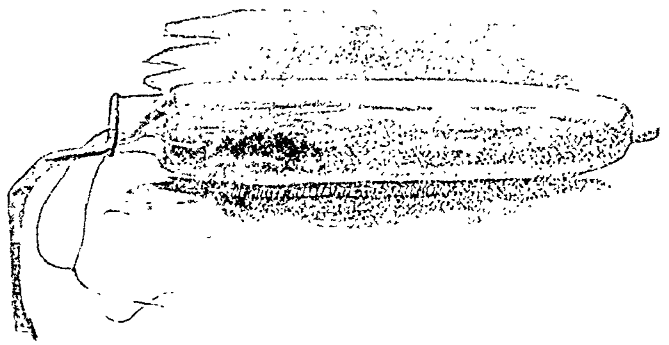

Fig. 6.—Showing aseptic tent cover with expanded tent within after it has been removed from the cervix.

The price of the case complete is so reasonable that it is certainly within the reach of every practitioner.

In making examinations or doing minor operations at private houses, the bed or couch should never be used. A kitchen table is easily obtainable in every house, and this can be readily converted into an examining table. This should be placed conveniently near a window and covered first, either with a blanket folded several times or a thick quilt. Over this is placed a fresh, clean sheet, which is folded over at the corners and pinned down with safety pins. The rubber air-cushion is placed in position at the foot of the table and everything is ready for work. On a smaller table or chair placed to the right of the physician, as he faces the foot of the table, are placed the trays containing the instruments to be used. Then the irrigating reservoir is filled and the hook screwed into the window-facing, preferably to his left. Before beginning there should be placed in readiness an extra pitcher of the solution for refilling the reservoir when it is exhausted, so there may be the least possible delay during the procedure.

Where slow, gradual dilatation of the cervix by sponge or laminaria tents is required, I have succeeded in accomplishing it in a perfectly aseptic manner by employing the sponge-tent cover made of rubber. These have been made for me by the Miller Rubber Mfg. Co., of pure gum, very thin, and they stretch easily. Hence, they offer the least possible resistance to the expansion of the tent. The method of using them is as follows, viz., a narrow strip of sterile absorbent gauze is folded over the point of the tent and down along each side, one end being left longer than the other. The gauze is now wet by dipping it into water. The cover, previously sterilized, is then slipped over the tent covered with the strip of gauze, the long end of which is left hanging out of the mouth of the cover. The tent is grasped in a pair of forceps by its lower end outside of its cover and inserted into the cervical canal. The vagina is then filled loosely with absorbent gauze which is made thoroughly wet. The capillary action of the gauze strip over the tent within the cover takes up the water from the gauze in the vagina and wets the tent, causing it to expand. Thus the tent expands inside of the cover and does not come in contact with the canal. Therefore a perfect aseptic, gradual dilatation is secured.

The physician's first duty is always to his patient, and her interest and security should be kept constantly before him. She must, therefore, be impressed with the importance of what is being done and must under no consideration be permitted to think any detail unimportant, or that she may with impunity neglect herself or miss appointments. Above all things, the case must not be dismissed nor must the patient be permitted to discontinue treatment until cured. She must be made to realize that relief of symptoms does not necessarily constitute a cure, and that the physician is the only one competent to decide this point. He must have her entire confidence, to be successful. Without this he would better not undertake the case. Her confidence can not be gained by incompetent and imperfect methods.

DISCUSSION.

Dr. J. M. Duff, Pittsburg—This has been a very important paper, one especially directed to the general practitioner. I want to call attention to one thing that I think the Doctor did not elucidate so as to bring out the best results, that is with regard to washing out the vagina. If you take the trouble to experiment, you will find that if you flush out the vagina and clean the vulva, and then go to work with your hands afterward, you are going to carry germs into the vagina. Hence, the important thing is to get the vulva clean. The normal secretions of the vagina are germicidal in themselves. If you do not sterilize the cervix before you introduce instruments into the uterus, where you have a catarrhal endometritis without the presence of pus-producing germs, you are very liable to carry them in and produce a septic condition. No matter whether or not we have a leucorrhea, it is a well-established fact that we do have latent germs in the cervix which can be carried up and infect the uterus. I may have misunderstood the Doctor, and if I have he did not bring this point out plainly.

Dr. L. H. Dunning, Indianapolis—I do not quite understand whether the essayist recommends his technique as a routine practice in general office work, or not. If so, and he had twelve patients, it would require one hour to scrub the hands and another hour for scrubbing the vagina, and if the doctor has only two hours to spend in his office, there would be absolutely no time left for treating more than one patient. It seems to me that in applying tampons to the uterus, where the cervix is not entered, it will not be necessary to adopt all of his technique. I am under the impression that we can disinfect the vagina just as well by scrubbing as by irrigation and in one-half the time. If I desire to make an irrigation of the uterus I should disinfect by scrubbing with antiseptic soap and sterile cotton, using the Sims' speculum. We can do better in ten minutes than by irrigating half an hour, and the method is a much more cleanly one.

Regarding the technique for the ordinary application of the tampon in a private home, I think that if we have the nurse prepare everything for us before leaving the office and have the patient properly cleaned before we get there, it will be unnecessary to adopt this technique. The point of objection is the time it takes. I am sure that I could not get through with half my work if I had to go through all this preparation. The method I have resorted to is to have my nurse prepare my bag, sterilize two sets of instruments wrapped in sterile towels, so that I can make two visits. I instruct the patient on a previous visit how to prepare herself, and as soon as I arrive she takes the proper position and a very little time is lost in treating the case. After having treated two cases I return home for another outfit.

Dr. J. Wesley Bovee, Washington, D. C.—I consider it almost an absolute impossibility to sterilize the hands by a five-minutes scrubbing with antiseptic soap or anything else. You may make a culture and find them negative, but the hands are not sterile nevertheless. I should suggest the use of the rubber glove if we want to be particular, which for my part I am not. I do not believe that we can scrub the vagina and vulva sufficiently well for sterilization without an anesthetic. In the second place, I believe that the vaginal secretion is usually able to take care of the vagina. We do not need so much scrubbing if the ordinary well-washed hand is passed through the vulva widened by the fingers of the other hand. This is readily realized by recalling the many normal opportunities for such infection. If we went through all this technique in minor gynecology, we certainly would not have sufficient time to do our work, if we have more than one patient. Furthermore, you go to the house of one patient and before you can see another you must go home and sterilize your instruments.

Dr. William H. Humiston, Cleveland—I was very much interested in Dr. Goelet's paper. I yield to no man in carefulness in making examinations. I do not believe, however, that it is necessary to follow absolutely Dr. Goelet's instructions in making an examination. As Dr. Duff has stated, the danger from infection is not from the vaginal secretion, but from what exists on the vulva. I clean thoroughly the external parts. The ordinary office treatment of the uterine organs is harmful. I have yet to see the first case of any gravity successfully treated by ordinary office treatment, but I do meet with many cases which if they had been properly and aseptically treated early while the condition was a simple one, would not have gone on to the condition where they required active surgical interference. I had a physician come to me a short time since wanting to know how I could explain a certain case. A patient came to him with a leucorrheal discharge and suffering from dysmenorrhea. He treated tentatively for a time, but she did not improve. Finally, he concluded to curette the uterus a little at a time every third day, in his office, permitting the patient to walk home afterward. Within a week patient had a chill, high fever and an active pelvic inflammation. On examination, he noticed a marked change, the uterus being fixed and the roof of the pelvis as hard as a board. He wanted to know what to do. You can readily understand that he converted a simple condition into a complicated septic process by not instituting proper aseptic treatment and operation. These cases should be treated thoroughly. If after an examination a chronic condition is found, I do not believe that the case can be cured by office treatment. It requires a minor operation with hospital facilities. Then you can anesthetize, cleanse the vagina and vulva, which can not be well done without the aid of a brush, and you avoid many perils of careless office treatment with non-sterilized instruments. My office work is limited almost exclusively to examinations; further treatment, if necessary, is given in the hospital.

Dr. M. F. Porter, Fort Wayne, Ind.—In the cleansing of the vagina, or any part, I am of the opinion that we oftentimes do harm with the stiff brush. A few bacteria will not do very much damage in the presence of an intact covering. It is this idea that has led me to use something soft, like gauze pads or sponges, in cleansing the vagina and vulva. Then, I have the satisfaction of knowing that when I am through with my cleansing process, if I have not obtained an aseptic condition, I have at least not increased the number of infection atria. I do not believe that any amount of douching or distension, or both, will leave the vagina clean. I simply want to enter my protest against the use of a stiff brush. Another point in connection with aseptic technique: The doctor has referred to the fact that all of us are occasionally guilty of lapses in our technique. One of the best ways to rid oneself of these is for the doctor himself to have it distinctly understood by all those around him that the humblest individual is not only free but is invited to call the operator or his assistant's attention to any lapses which may occur. Each one of my assistants and nurses is told when he comes to work for me, that if he sees me about to err in my aseptic technique, he is at perfect liberty to call my attention to it and I thank him for doing so. None of us are perfect and we must never forget it.

Dr. Goelet, closing the discussion—I have learned considerable from this short discussion. One thing I have learned particularly is the necessity for such a paper as this. Asepsis of the vulva can be accomplished only by scrubbing, but for ordinary office work such an irrigation as I have described is sufficient. My paper is upon minor, not operative, gynecology. With this douche we also cleanse the vulva and when necessary to have it especially clean, I ask the nurse to scrub it. My portable rubber reservoir I use for work at the patient's house, where irrigation is required. As to cleansing the hands I agree that it is a very difficult matter to free the hands absolutely from germs, but I have had bacteriologic tests made of the hands after scrubbing them for five minutes with the antiseptic liquid soap mentioned, and all cultures taken after such scrubbing have remained sterile in every instance. There should be no objection to the time required for cleansing the hands. I am surprised that such objection should be raised. It takes nearly five minutes for the patient to get ready and to put her in position on the table, and while the nurse is preparing the patient, you can be scrubbing your hands. You owe this to your patient. Besides, such methods are going to bring more patients than slip-shod methods. There is no doubt about that. Women appreciate cleanliness in their physician.

I regret that there was not more said about the sponge-tent cover, as I have found it very satisfactory, although I do not restrict myself to that method of dilating the cervical canal.

Auto-Intoxications in Tropical Climates.—*Crespin* describes a hepatic form of typhoid fever common in Algiers and attributes the gravity of infections in tropical climates to insufficiency of the liver. The high temperature and the high hygrometric condition create a uniform medium unfavorable for the play of the reflexes. Consequently the emunctories, and especially the liver, are deprived of the excitations necessary for their normal functioning and hence remain torpid. On these grounds he has been administering liver extract in several cases of infections in his tropical practice, and has been highly pleased with the results; the hemorrhages and the delirium in particular rapidly improved. He recommended this organotherapy for further experiences at the International Medical Congress.

RESECTION AND ANASTOMOSIS OF THE DIVIDED URETER.*

HOWARD A. KELLY, M.D.
BALTIMORE, MD.

I desire to lay before the Section on Gynecology several matters in connection with resection of the ureter; and I shall take the liberty of including under my title not only those cases in which a piece of the ureter is sacrificed and the ends brought together—uretero-ureterostomy, resection in the stricter sense of the term —but those cases as well in which the vesical end of the ureter is sacrificed and the upper end is anastomosed directly into the bladder—ureterocystostomy—cases which for practical purposes may be included in the same category.

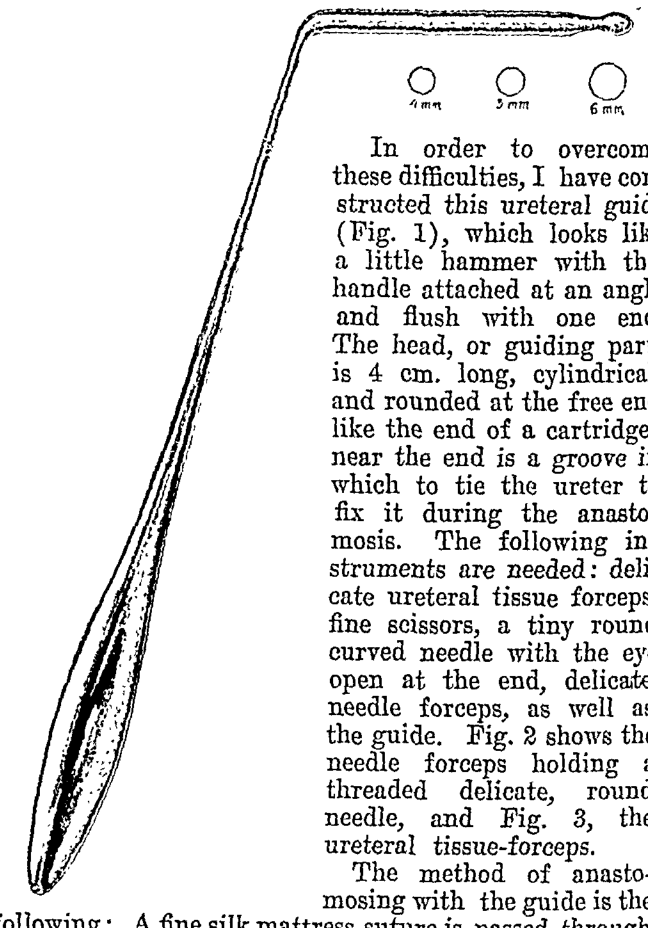
The importance of my subject is enhanced by two factors, measured by the importance of the ureter as an emunctory, and by its liability to injury in the course of an abdominal or of a vaginal operation. The difficulty in the way of a successful performance of a ureteral anastomosis can only be appreciated by one who has tried for the first time to secure accurate apposition of structures so delicate without unduly injuring the tissues and without allowing the silk sutures, which must be used, to appear on the mucous surface to form nuclei for the subsequent formation of calculi. I take it that a ureteral anastomosis is about as difficult and as delicate a piece of surgical work as we are called on to execute upon the human body, fully as delicate as the most difficult operation on the eye.

Injuries of the ureter requiring anastomosis are almost exclusively surgical, that is to say, they are produced in the course of operations when they can often be detected at once and immediately repaired. It is a fact of the utmost importance for the successful anastomosis of the injured ureter that the injury is almost invariably confined to the pelvic portion of the ureter, and if any part is sacrificed the loss is limited to the pelvic end. The injury is, for the most part, involuntary on the part of the operator, as when he cuts a ureter for a blood-vessel, or unwittingly picks it up, as I did recently, along with the ovarian vessel at the pelvic brim and ligates and divides it there. In other instances it is torn out of the pelvis with an adherent ovarian cyst, myoma, pyosalpinx, extrauterine pregnancy, or tubercular mass. A voluntary sacrifice is made when the ureter passes through a carcinomatous mass in the broad ligament.

It is my desire to-day to throw some light upon the important practical question, how to deal with a divided or a resected ureter. In the first place it is important to make sure that the ureter is a live one. Occasionally the disease which necessitates the pelvic operation has so completely occluded the ureter that it is dead, and if brought out into the surface of the body no secretion escapes from it. This has happened in some five cases which I have collected from the literature; one of the first was a patient of Schröder's, in which the divided ureter was sewed into the abdominal incision but no secretion ever escaped from it. One of the last was a case of Dr. Fullerton, also seen by Dr. C. P. Noble, in Philadelphia, with the view of determining the functional value of the ureter. I would pass my hand into the abdomen and see if the patient had a normal kidney on that side. If it proved to be atrophied or sclerotic I would then not go to the trouble of making a delicate anastomotic operation.

There are two ways of anastomosing the injured ureter: 1, anastomosis of the ureter into itself—uretero-ureterostomy; and 2, anatomosis into the bladder—ureterocystostomy.

Uretero-ureterostomy is to be preferred when both ends are accessible, and when there is no obstruction between the lower end and the bladder, and when the lower end does not have to be sacrificed as in extensive carcinoma. Anastomosis into the bladder is the best way to restore the continuity of the urinary tract when the lower end of the ureter has been destroyed, is blockaded, or is inaccessible. Anastomosis of the ureter into itself is best adapted to joining the divided ends in the posterior part of the pelvis, between the pelvic brim and the broad ligament. The success of an anastomotic operation depends on the accurate union without injury of the delicate ureteral structures; and this is rendered difficult by their flaccidity and sometimes by the difference in caliber.



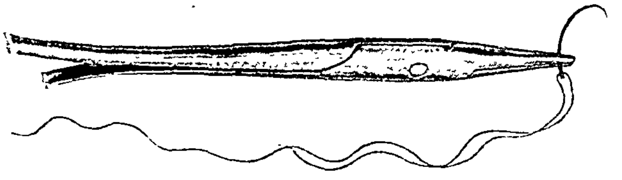
In order to overcome these difficulties, I have constructed this ureteral guide (Fig. 1), which looks like a little hammer with the handle attached at an angle and flush with one end. The head, or guiding part, is 4 cm. long, cylindrical, and rounded at the free end like the end of a cartridge; near the end is a groove in which to tie the ureter to fix it during the anastomosis. The following instruments are needed: delicate ureteral tissue forceps, fine scissors, a tiny round curved needle with the eye open at the end, delicate needle forceps, as well as the guide. Fig. 2 shows the needle forceps holding a threaded delicate, round needle, and Fig. 3, the ureteral tissue-forceps.

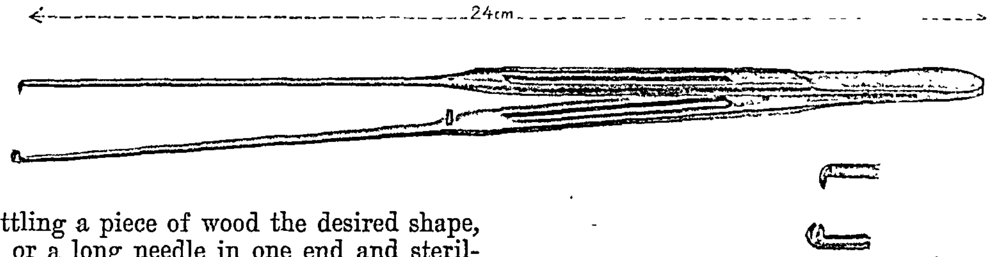
The method of anastomosing with the guide is the following: A fine silk mattress-suture is passed through the under surfaces of the cut ends and tied, bringing them snugly together. A longitudinal slit is then made in the upper part of the ureter 2 cm. distant from the end, just large enough to admit the guide easily. The rounded end of the guide is then pushed through the slit into the ureter down through its open end and well into the lower end, where it is loosely tied behind the swelling at the head to hold it in place during the passage of the rest of the sutures (Fig. 4). The end-to-end anastomosis is now completed by passing fine silk sutures, either interrupted or mattress, with the sides very close together, at intervals of from one to one and a half millimeters, including all the coats except the mucosa. During the suturing, the ureter can be rotated from side to side by moving the handle of the guide. At the completion, the string tied around the lower end of the guide is cut and the guide withdrawn. The success of the suturing may now be tested by injecting water with a syringe through the cut and seeing it flow freely down toward the bladder without leakage at the junction of the ends. The slit is next readily closed by three or four fine mattress sutures of silk as after any other simple ureterotomy.

---

*Presented to the Section on Obstetrics and Diseases of Women, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

I have the guides made in three sizes. When there is a marked difference in caliber between the upper and lower portions of the ureter, I use the larger size to dilate the smaller end and to facilitate the exact end-to-end approximation. There is a good deal of just complaint about the multiplication of special instruments, but no instrument is *de trop* which facilitates a difficult and a delicate operation. The surgeon who rarely has to do these operations can easily extemporize a guide by whittling a piece of wood the desired shape, fixing a thread or a long needle in one end and sterilizing this very satisfactory makeshift and using it as above described.





The anastomosis of the ureter into the bladder is effected in a similar way. A hole is made in the top peritoneal surface of the bladder and the guide slipped in and the right or left vesical cornu pushed out in the direction of the divided ureteral end, and an opening made at the nearest point, just large enough to admit the ureter. The end of the guide is then slipped well up into the ureter and tied, and the ureter, with its lower end slit up for at least half a centimeter, is drawn well into the bladder and stitched on all sides to the muscular vesical wall. After this the guide is removed and the abdomen closed with a small gauze drain in event of leakage.

The following cases are ureteral anastomoses I have made in the Johns Hopkins Hospital for a variety of injuries:

Case 1.—Cancer of the cervix, involving the ureter on the right side; vaginal operation. The anterior portion of the ureter was deliberately sacrificed with the uterus and the upper end anastomosed at once into the bladder. Recovery; anastomosis perfect,

Case 2.—Ureter involved in a cancerous ovary in a woman 72 years old. Deliberate sacrifice of the ureter from the pelvic brim forward. Ureter stitched into bladder. Recovery; no leakage.

Case 3.—Cancer of the cervix, abdominal operation. Ureter involved; sacrificed. Anastomosis into the bladder. Recovery; no leakage.

Case 4.—Ureter attached to a large fibroid tumor involving ilium, cecum and vermiform appendix. Resection of 9 cm. of ureter, ends brought together. Some leakage at first; afterward perfect recovery.

Case 5.—Ureterovaginal fistula and vesicovaginal fistula; anastomosis of ureter by abdomen into bladder. Recovery; leakage from vesicovaginal fistula.

Case 6.—Ureter involved in malignant ovarian tumor. Enucleation with removal of almost the entire pelvic ureter; anastomosis into the bladder. Death on the third day from unknown cause. Autopsy not allowed.

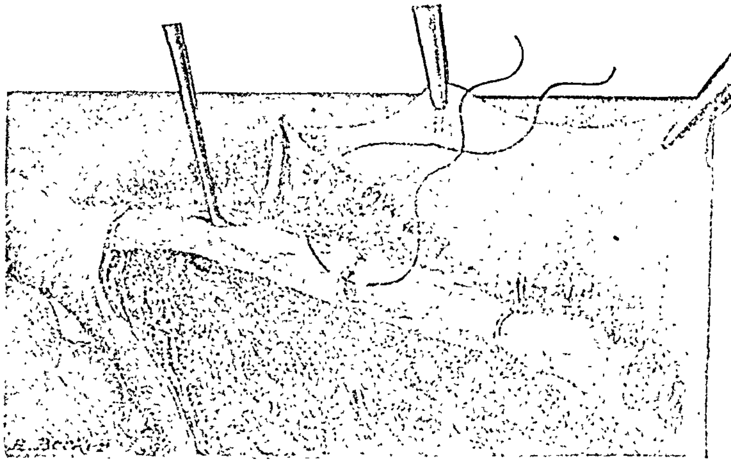
These operations were all done by the older free-hand method, and I have not yet used the guide on the living subject.

Case 1.—Ureter imbedded in a mass of carcinomatous tissue. Divided 2 cm. from bladder; resected and upper end implanted into the bladder; recovery. (Gyn. No. 6831.) Mrs. S. L., white, aged 35 years.

Diagnosis: Carcinoma cervicis uteri, extending laterally into the broad ligaments well onto the lateral walls of the pelvis, and anteriorly well out into the perivesical tissue.

Operation: 1, Thorough curettage of the cervix, removing as much as possible of the friable carcinomatous tissue. 2. Catheterization of the ureters. 3. Abdominal hysterosalpingo-oöphorectomy. 4. Ureterocystostomy.

After removing the uterus, tubes and ovaries a distinct carcinomatous nodule still remained on the right side, extending well out to the pelvic wall and upward to the bladder. After some dissection the ureter was found markedly displaced, running downward from the bladder and then sharply curving on itself to run directly upward, being entirely surrounded by diseased tissue. It was found impossible to dissect out this nodule without injuring the ureter, so it was at once severed 2 cm. below the bladder. The nodule was then thoroughly and most carefully dissected out.



Implantation of the ureter into the bladder was accomplished in the following manner. A sound was introduced into the bladder and pressed firmly down upon the bladder wall a little anterior to the orifice of the ureter; the bladder wall was then incised just over the sound; next, the lower end of the ureter was split for .5 to 1 cm. down its lumen to avoid constriction. This end was then introduced over the sound and passed into the bladder. The next step was to very accurately approximate the bladder wall around the ureter, the end of which was now standing erect inside of the bladder. Approximation was neatly and accurately accomplished by passing catgut sutures through the outer portion of the bladder surface, then just lightly catching the surface of the ureter, catgut sutures only being employed. The first few of these sutures were passed just at the edge of the bladder [illegible] then into the ureter; the [illegible] t [illegible] ner hold o [illegible] and a larger bite into the ureter at a greater distance on its surface from its point of entrance into the bladder.

The patient made a perfect recovery, with no leakage from the bladder.

Case 2.—Ureter surrounded by carcinomatous tissue and resected from the pelvic brim to the bladder. Anastomosis of upper end of ureter into bladder. Recovery. (Gyn. No. 7372). Mrs. M. F., white, aged 72 years.

Diagnosis: Cystoma of both ovaries. Carcinomatous degeneration of the right cystoma.

Operation: 1. Abdominal hysterosalpingo-öophoro-cystostomy. 2. Ureterocystostomy.

Removal of the cystomata with the tubes and uterus was extremely difficult—slow and painstaking—on account of numerous exceedingly dense adhesions to the small intestines and the rectum on all sides. When the left cystoma and the uterus were tied off and freed they still remained attached to the cystoma on the right side, which was also gradually freed, but was found to contain at its base a cancerous mass extending down in the broad ligament to the ureter, which it surrounded. The tumors and the uterus were then removed in one mass and the remainder of the operation directed toward the removal of the cancerous tissue in the broad ligament. This was slowly enucleated by tying on all sides in the sound tissues and removing the ureter with it from the pelvic brim forward to its vesical portion. The ureter was then implanted into the bladder in the following manner: The bladder was separated anteriorly from its attachments to the anterior abdominal wall sufficiently to throw it well back and allow the ureter to reach it near the fundus. On the right side of the pelvis an opening was made through the peritoneum, where it was reflected from the bladder onto the pelvic wall; the ureter was carried through this and thence into an opening made into the bladder, where it was securely stitched by several small silk sutures. The junction of the ureter and bladder was in this way made extraperitoneal. The opening into the peritoneum was about 3 cm. from the point of entrance into the bladder. The connective tissue and the bladder wall were stitched over the point of junction of the ureter and bladder, thus reinforcing the line of original sutures. The implantation of the ureter in this manner puts it on considerable tension.

Result was excellent. No urinary fistula nor any sign of leakage from bladder.

Case 3.—Ureter embedded in carcinomatous tissue; its lower 5 or 6 cm. resected; upper end implanted into bladder. Recovery. (Gyn. No. 7510.) Mrs. S. C., white, aged 56 years.

Diagnosis: Carcinoma cervicis uteri. Bicornuate uterus with left rudimentary horn, left tube absent.

Operation: 1, Curettage of cervix uteri. 2. Catheterization of ureters. 3. Hysterosalpingo-öophorectomy.

The operation was begun by the abdomen on the left side. The first ligature was applied at the junction of the round ligament and the ovarian ligament, the ovary being left behind. Dissection was continued along the wall of the pelvis until the ureter was exposed and bared to its entrance into the bladder, 5 to 6 cm. The vesical peritoneum was then pushed well down; the ureter was pulled gently toward the pelvic wall and the dissection continued toward the vagina beneath it, all vessels being tied as they were reached. The right side was begun in the same way. On reaching the ureter it was found passing through the carcinoma. It was dissected free up to its entrance into the growth, where it was cut off. The dissection toward the right pelvic wall was continued apparently outside of the carcinoma. The vagina was now entered anteriorly and the enucleation continued around the vagina, leaving a cuff of vaginal wall on the uterus on all sides. The uterus, with its carcinomatous extension, was then removed. A long clamp was pushed into the bladder *per urethram* and an opening made by cutting down on it from above. The end of the ureter was split for about 5 cm. A silk suture was then passed through the ureter and through the bladder opening and the bladder wall at a lower point and the end of the ureter drawn into the bladder. It was sutured here with fine silk sutures. Peritoneum was brought over both ureters.

Result excellent. No leakage from bladder.

Case 4.—Ureter, terminal portion of ileum and vermiform appendix and commencement of large bowel inseparably attached to a large abdominal fibroma. Resection of 9 cm. of ureter, 16 cm. of ileum, 14 cm. of large intestine, and removal of vermiform appendix. Recovery with a persistent ureteral fistula. (Gyn. No. 7521.) M. P., negress, aged 33 years.

Diagnosis: Large solid abdominal tumor, extremely vascular, having inseparable attachments to the bowel and the ureter. (It was found by microscopic examination to be a fibroma.)

Operation: An attempt was first made to shell the tumor out of its capsule, but the bleeding was so profuse on incising it that this plan was abandoned. The only remaining plan of procedure was to remove the entire tumor with the adherent portion of the bowel and ureter. The vermiform appendix was seen on the under surface of the tumor, on the upper surface the head of the cecum and ascending colon spread out with the lower end of the ileum. The portion of the intestine removed includes the terminal 16 cm. of the ileum and the proximal 14 cm. of the large bowel. The portion of the ureter removed measures 9 cm. in length. The ends of the intestines were next united by end-to-end anastomosis without the aid of bags or LaPlace forceps, three preliminary sutures bringing the ends into approximation; next a row of mattress fine-silk sutures and a few intermediate Lembert sutures. The mesentery, which well supplied the intestine with blood at the point of anastomosis, was united by sutures. The ends of the ureter were next united by end-to-end anastomosis. The upper end was much larger than the lower, the ureter being dilated above the tumor and atrophied below it. The lumen of the kidney end of the ureter was at least twice the size of the bladder end. Suturing was difficult and the approximation was, on account of the difference in size of the lumina, not as satisfactory as could have been desired. After completing the anastomosis, pressure on the ureter above caused a distension above the point of union. The ureter was also quite tensely stretched, owing to the removal of so large a section of it. A gauze drain was placed in contact with both anastomoses and brought out of the lower angle of the wound.

The patient made a good recovery, but was discharged with a persistent ureteral fistula.

Case 5.—Ureterovaginal and vesicovaginal fistulæ, surrounded by dense scar tissue. Division of the ureter just in front of the uterine artery and closure of the vesicovaginal fistula. Recovery, with persistence of vesicovaginal fistula. (Gyn. No. 7569.) L. C., white, aged 46 years.

Diagnosis: 1. Adherent, myomatous uterus. Tubes and ovaries also adherent. 2. Ureterovaginal fistula. 3. Vesicovaginal fistula.

Complications: 1. Scar tissue involving the vaginal opening of the ureter. 2. Periureteritis.

Operation: (Twenty-four days prior to the present operation the patient had been operated on for complete laceration of the rectovaginal septum and at the same time an unsuccessful attempt was made to close the ureterovaginal fistula.)

After removing the uterus, tubes and ovaries in the usual manner, from left to right the stump of the cervix was grasped with tenaculum forceps and pulled up and to the right. The ureter was exposed just below the pelvic brim by pulling open the layers of the broad ligament. It was about two and a half times its normal size and injected, not white. The ureter was caught and dissected out by carrying the finger under it and pushing on down and freeing it forward without detaching it from the peritoneum. In this way the vessels crossing the ureter were brought up into view and tied without risk of involving the ureter. The ureter was then tied well forward just in front of the uterine artery and divided back of the tie. The bladder was now opened for 5 cm. in the median line and its interior inspected. It was found healthy and the vesicovaginal fistula was seen out by the left pubic ramus, 8x3 mm. The bladder was opened in the left cornu at a point near the ureter by introducing forceps and pushing the wall out at this point and cutting down on the forceps. The ureter was incised for 7 mm. and then drawn into the bladder by fine forceps passed in through the incision above and out of the hole made for the ureter. The ureter was then sewn into the bladder opening with fine silk, grasping all but the mucosa in the bladder wall and ureteral wall.

The vesicovaginal fistula was closed by denuding the mucosa and uniting with fine catgut.

The incision into the bladder above was closed with a line of catgut sutures. A finger was thrust under the peritoneum on the left side, making a hole down to the ureteral anastomosis for an extraperitoneal gauze drain. The peritoneum was united over the ureter and the bladder and peritoneum closed entirely.

There was for a short time after operation some leakage from the bladder, a small amount of urine escaping through the abdominal incision via the drainage tract. This fistula closed entirely before the patient was discharged from the hospital.

A vesicovaginal fistula persisted after the operation.

Case 6.—Ureter involved in a malignant tumor, resected above the pelvic brim; implantation of the upper end of the ureter into the bladder. Sudden death from unknown cause on the third day after operation. (Gyn. No. 7653.) Mrs. R. D., white, aged 67 years.

Diagnosis: Left cystoma ovarii with malignant disease at its hilum extending into the broad ligament.

Operation: 1, Hysterosalpingo-öophorocystectomy. 2. Ureterocystostomy.

When the cyst on the left side was brought out it was found to be anchored fast, the left broad ligament being infiltrated with a mass of dense nodules. It was impossible to expose the broad ligament and see the vessels, so I lifted up the sigmoid and cut the peritoneum over the pelvic brim on the outer side and dissected it up and exposed and ligated the ovarian vessels first 3 cm. above the pelvic brim, then on the ovarian side and cut between the ligatures. The left round ligament was then enucleated from the pelvic connective tissue, clamping the left uterine cornu and all bleeding vessels and lifting it up *pari passu*. The ureter, which was adherent to its under surface, was cut on the front of the broad ligament and posteriorly above the pelvic brim. The anterior end was about half the size of the posterior, small and delicate, and retracted out of sight, being found only at a later stage—after opening the bladder and passing a catheter down the ureter from the vesical end—when it was tied to prevent any possible reflux of urine. The entire uterus and the right lateral structures were removed.

The next step was the anastomosis of the ureter into the bladder. I did not try to bring the two ureteral ends together, as the front end was so small and restricted, and moreover the bladder could be brought farther back than could the vesical end of the ureter.

The bladder was loosened and pulled back on the left side until it touched the posterior brim of the pelvis. I then opened the bladder by an incision 5 cm. long in the median line anterior to the peritoneum. The urethral and ureteral orifices were seen and there was no disease in the bladder. The portion of the bladder which could be displaced farthest back toward the ureter was found anterior to the left vesical cornu. An artery forceps was pushed through at this point, catching the ureter and drawing it into the bladder. It was split 5 mm. and turned open and caught with four mosquito-forceps, and then sutured from the vesical side, catching the whole thickness of the ureter and the mucosa and submucosa of the bladder. In this way was accomplished a perfect attachment of the ureter without any narrowing of its lumen, which opened trumpet-like into the bladder. The incision into the bladder above was closed. The bladder was then drawn up and attached to the pelvic brim and to the sigmoid.

After operation there was some leakage from the bladder, as indicated by the escape of urine via the pelvic drain.

The patient died suddenly on the third day after operation from an unknown cause. Autopsy was not allowed.

DISCUSSION.

Dr. L. H. Dunning, Indianapolis—I was very much interested in the paper of Dr. Kelly, because it brings up so clearly a subject which confronts us occasionally in our operative work. I can see how the advice will be of assistance to us. Two years ago, I encountered a case such as he described, but I was not provided with special instruments for the purpose of bringing the ureter into the bladder. I finally resorted to a very simple method, which enabled me to effect that purpose with very good results. The ureter in this case was displaced by a pelvic cellular abscess occurring seven weeks after confinement. It was carried over the top of the abscess and accidentally torn in the operation. I introduced a uterine sound into the bladder through the urethra, carrying it to the point nearest the severed ureter, cut down on it, carried it through, reaching the ureter, into which I introduced the sound. Then, I gradually drew the ureter into the bladder, and fixed it there without any stretching. That little device of carrying it over the end of the uterine sound is what made our operation easy. I encountered a case a short time ago, in which I desired to graft the end of a torn ureter into the bladder, although subsequently I was glad I did not do such grafting. It was a case of cancer of the uterus, with suppuration of one tube and ovary. During the operation we injured the ureter, and four weeks afterward, when the patient had recovered from the operation I desired by abdominal section to fasten the ureter into the bladder. I washed out the ureter a few times, hoping to clean out the pus which had accumulated there, in order to prevent infection of the kidney. We found the pelvis of the kidney already infected so that I desisted from doing anything more to the ureter. I think extirpation of the kidney was in that instance the proper procedure. It was accomplished with the most happy results.

Dr. J. Wesley Bovee, Washington, D. C.—I did not hear all of Dr. Kelly's paper, but we all know the careful, scientific work that Dr. Kelly has done in this regional anatomy and pathology. The subject is one of considerable interest to me as I have spent much time on it in the last few years, having had a few cases of this kind. Many times this operation is necessary for cases other than accidental injury during the operations. A large proportion of injuries follow childbirth, as ureterovaginal fistula; a certain proportion are due to congenitally abnormal openings, abscesses rupturing into the ureter, tuberculosis and diseases of the ureter itself. I think there have been about 80 cases of ureteral anastomosis into the bladder, about equally divided between those due to injury and those due to disease.

Of the various operations I think uretero-ureteral anastomosis is the best. The next best is the switching of the ureter into the bladder; the next, into the vagina; the next, into the bowel, which is a much discussed question at the present time, and lastly, switching the ureter to the surface of the body. In the latter, infection is positive, whereas in implantation in the bowel there may not be any infection. The experimental work with the latter method is probably not as satisfactory on dogs as on the human being, owing to the small size of the dog's ureter. Then, too, we have no control over the animal after operation such as we would have over a patient. I think the extraperitoneal method of attaching the ureter to the bladder is better than the intraperitoneal, as it is practically a minor operation. The only danger, as Dr. Kelly mentioned, is the too great tension on the ureter. Pozzi found that in one of his cases ten months after an operation for hernia, the ureter was very markedly distended and at the junction of the bladder it was very much contracted. If there is too much traction on the ureter the caliber is decreased at the bladder junction.

Another point is to make the anastomosis as obliquely as possible. It is impossible to establish a condition anything like the normal, because of the little muscular structure running from the ureter to the orifice of the urethra, tending to pull down the mouth of the ureter as the bladder expands. About two years ago, in a case of cancer of the uterus, I found the ureter passing through a cancerous mass, and I removed the lower inch and a half, transplanting it into the bladder. That was a case of injury to the ureter and of transplanting it into the bladder by election. The patient is still alive and free from trouble. Dr. Polk, of New York, and Krause have performed this operation for the same purpose.

Dr. Kelly, closing the discussion—In anastomosing the ureter in the bladder I follow one of two plans. I either bring the ureter in opposition with the vesical opening by using one of my guides, or I draw the ureter well into the bladder by means of a pair of alligator forceps suggested by Sänger for this purpose. The forceps are inserted through the urethra, and then through the bladder wall, and so used to pull the ureter into the bladder, when it is held and sutured there. I have a guide on the end of the forceps, in the form of a long tongue, which projects into the ureteral lumen, thus preventing any contraction of the ureter. The statistics are so meager that it is desirable to have all cases recorded, and I am sure there are many.

LESSONS FROM A FIRST SERIES OF ONE HUNDRED CATARACT OPERATIONS.*

F. T. ROGERS, M.D.
PROVIDENCE, R.I.

The man who fails to study his case records, and thus gain confidence by reason of his successes and profit by his failures, does not take advantage of the best way of perfecting his medical education, begun in college; he is at his graduation but ready to learn. The successful physician is one who appreciates this fact and finds in each case fresh instruction, in each success added confidence, in each failure a warning of incomplete preparation.

It is neither because I can add to the sum of human knowledge by a recital of personal experiences, and instruct this Section concerning the technique of cataract extraction, nor gain personal glory or added notoriety that I report these cases, but because during six years of attendance at these meetings I have not heard adequately discussed the results of cataract extraction from a beginner's standpoint.

Masters of operative skill have reported their cases by hundreds. We are wont to listen with admiration to their recital of good results, but aside from the incentive to renewed exertion we gain little practical good. I am speaking to-day to the younger element, the tyros of operative skill, in the hope that profit may result to them from the discussion of evident mistakes and the bad results obtained just as I have personally gained by a study of these records.

I am at the start impressed by one fact, that a certain proportion of the bad results I have obtained has been due to the poor selection of cases. The young man beginning operative work is apt to allow his judgment to be warped by his desire for another operative case. The eagerness to operate overcomes the possibility that a successful result will not be obtained, and when but moderate vision is secured it may be due to the fact that the vision was not there as well as to some fault of the operator.

I am convinced that not enough attention was paid to the general condition of the patient, and that the ideas advanced before this Section three years ago by Dr. Knapp in regard to the effect of any systemic disturbance on the ultimate result were not sufficiently impressed on me at the time. The existence of bronchitis, nephritis and rheumatism in patients undoubtedly influenced the healing process, although prior to the operation this did not seem important.

If, however, we operate upon patients to benefit them and not to gain a record for perfect vision, even partial success is to be desired if it ameliorates the condition and improves in any degree the vision of the patient. The operator who can change total blindness to even ability to get about, is deserving of some credit. As an evidence of this I cite one case:

Case 52.—Mrs. M. W., 64 years of age, suffered, in 1896, from acute glaucoma of the right eye, for which an iridectomy was done five days after the onset of the disease, when the patient was first seen; but the resulting vision was nil. L. V. was at that time 0.5 with +1.50. Two years later glaucoma of the left eye occurred, for which an iridectomy was done within twenty-four hours with relief of pain and slight improvement of vision; but within a month the lens became opaque and the patient totally blind. There was good perception of light but poor projection and I decided to operate for possible relief after a frank statement to the patient of the possibilities of failure.

An easy extraction with dense capsule and a secondary discission gave her an ultimate vision of 18/200 with +13, and her later years have been rendered happier, at any rate. Although by current rating this operation can not be classed a success, to my mind it is one.

The series includes operations upon the following:

Senile cataracts of varying degrees of maturity	92
Traumatic cataracts	2
Congenital cataracts	5
Soft cataract	1

The preparation of the patient has included the careful cleansing of the lids, lashes and brows with soap and water and a solution of bichlorid 1 to 5000, and in hospital cases the application of a bichlorid poultice for twelve hours before operation. When any secretion was noted on its removal the operation was delayed until the existing trouble had been treated. Cocain was used in all cases except four congenital cataracts, and just before operating the eye was flushed thoroughly with a warm solution of boric acid. The instruments were sterilized either by steam or formaldehyde and placed in absolute alcohol, and all dressings were rendered sterile by steam. I have no knowledge that any eye was lost by reason of carelessness in the preparation of either patient or instruments.

The after-treatment was in the ordinary room or ward and with a subdued light, but without darkening it; with few exceptions all dressings during the first week were done by myself. The results in acuity of vision were as follows:

Vision of 1.0, 6 cases; vision of 0.9, 7 cases; vision of 0.8, 14 cases; vision of 0.7, 12 cases; vision of 0.6, 7 cases; vision of 0.5, 14 cases; vision of 0.4, 9 cases; vision of 0.3, 7 cases; vision of 0.2, 3 cases; vision of 0.1, 8 cases; count fingers, 3 cases; light perception, 4 cases; nil, 5 cases. Total, 100 cases.

This shows an average vision of 0.502 and, if 0.1 be assumed as useful vision, 88 per cent. of successes, 3 per cent. of partial success and 9 per cent. of failures.

The operative procedure was: Simple extraction, 18 cases; extraction with iridectomy, 66; extraction following preliminary iridectomy, 8; needling, 7; suction, 1; total, 100.

Concerning the method of operating, I am convinced that difficulty in making a clean corneal section has been increased and the success of the operation endangered by insufficient illumination. Once, I have been obliged to withdraw the knife and postpone the operation on account of inability to see the blade distinctly when introduced into the anterior chamber. I believe that a routine practice of illuminating the field of operation by a condensing light, electricity in the hospital and an acetylene light in private houses, is a decided help to success. Outside of special hospitals it is difficult to gain skilled assistance and the surgeon is compelled to rely on himself. It has happened in my earlier cases that, while the fixation forceps were held by an assistant, interest in the operation frequently distracted his attention from his own duties so that undue pressure was made with the forceps; hence for several years I have not used an assistant but, holding the fixation forceps myself, I am able to make counter-pressure against the knife and thus aid its introduction and exit.

---

*Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

A conjunctival flap was made in twelve cases, but there was so frequently a hemorrhage which obscured the field of operation that I have not lately used it save when accidentally made. In a large majority of cases the knife has, just before the completion of the section, been turned outward and the exit made in clear cornea about one millimeter from the sclerocorneal margin. Although such a section, it is stated, is more likely to entangle the iris and more liable to primary or secondary infection, it has not proved so in my experience. I have found the flap to close accurately, prolapse of the iris has been less frequent and I have seen no reason to discard the practice save that it is not advised in the books.

After the corneal section I remove the speculum, and make the cystotomy while holding the upper lid by pressure over the orbital arch. My losses of vitreous—seven cases—all occurred with the speculum in place. The accident has not occurred when the lid has been held.

Cystotomy has been made by the semicircular and crucial incision, and I am unable to detect any difference in the ease of extraction or the resulting condition of the iris and capsule. Simple extraction was done in but eighteen cases, the combined operation in sixty-six cases, and I am led to prefer the method with iridectomy for the following reasons:

1. In one sense it simplifies the operation, rendering it easier to expel the lens and soft cortical matter through the large coloboma, and lessens the frequency of secondary cataracts.
2. There is less danger of prolapse of the iris.
3. The clean excision of the iris is no more likely to cause inflammatory action than the traumatism to which it is subjected by the expulsion of the lens in simple extraction.
4. It requires less skill and delicacy of touch, and thus lessens the danger of complications.
5. With care in replacing the angle of the excised iris and any bits of capsule, there is no greater danger of incarceration in the lips of the wound.
6. It does not materially affect the mobility of pupil.
7. While the cosmetic effect is not so perfect as in the simple extraction, the upper lid so completely hides the coloboma that, even if the cosmetic effect was the desideratum instead of acuity of vision, there would be little in favor of the simple method.
8. Visual acuity is nearly the same; according to Gayet it is the same. In my cases the average vision in the cases of simple extraction is 0.48 and in the combined operation is 0.47. The proportion of complications in the two methods was as follows:

	Uncomplicated.	Prolapse of Iris.	Iritis.	Visual Acuity.
Simple operation; 18 cases	10 cases. 55 per cent.	5 cases. 27 per cent.	5 cases. 27 per cent.	.48
Combined operation; 66 cases	37 cases. 57 per cent.	1 case. 1.5 per cent.	14 cases. 21 per cent.	.47

The combined operation has its drawbacks: It is prolonged, more painful and possibly increases the danger of infection, although with the means at our command this is reduced to a minimum, but to the average man it is safer and gives as good or better results.

The ideal operation is the one with the preliminary iridectomy, and in eight cases where this was done there was uncomplicated healing in seven. Personally I am of the opinion expressed by many authorities that had I a cataract requiring operation I would have a preliminary iridectomy; one can hardly give better advice to a patient than that which he takes himself.

Artificial ripening of the lens was done in five cases, and was in every case entirely satisfactory. Preliminary iridectomy with gentle massage of the cornea sufficed to render the lens mature in from three to six weeks, and the extraction was invariably easy and satisfactory. The resulting vision was 0.3, 0.5, 0.9, 0.5, 0.7.

The suction operation was done once, with resulting perfect vision. The needle operation was done seven times with resulting vision of 0.3, 1.0, 0.9, 0.5, 0.6, 1.0.

Secondary discission was done in twenty-seven cases with a maximum increase of vision of 0.8, a minimum of 0.1 and an average of 0.4. Following the secondary operation there developed in four cases a mild iridocyclitis, in three a severe attack, but in all there was in time a complete subsidence of all inflammatory action.

Failure to obtain useful vision occurred in twelve cases. Of these, three are able to get about with difficulty, four have bare perception of light, and in five the eye was lost. This unfortunate termination occurred as follows:

Case 6.—A female patient, 65 years of age, was operated on at St. Joseph's Hospital. The modified Graefe operation was made without difficulty, and until the sixth day recovery was uneventful. She was treated in the open ward and on the evening of the sixth day a new patient was admitted and placed in the next bed. During the night a large psoas abscess was evacuated and the bed and bedding were well soaked with pus. Forty-eight hours later there was swelling of the lids, chemosis of the conjunctiva, and, in spite of treatment, panophthalmitis developed and phthisis bulbi resulted.

Case 38.—Simple extraction in a woman of 60 years. On removing the dressings on the second day there was found beginning panophthalmitis, and the eye was lost. I have no knowledge of the source of infection, save possibly this, that the operation was done in the presence of a number of physicians who were visiting the hospital and one had come directly from a case of puerperal septicemia.

Case 66.—Modified Graefe operation was made on a man of 75 years and in poor health. The operation was smooth, and aside from slight iritis there was an uninterrupted recovery but no vision. Examination showed almost complete detachment of the retina; it probably did not occur after the operation and it was an error of judgment to operate the case, although it may have occurred at the time of the extraction of the lens.

Case 89.—Female, aged 71 years, underwent a smooth operation and perfect convalescence until the eleventh day, when there was noted a slight puffiness of the lids with beginning chemosis of the conjunctiva. The dressings, solution of atropin and droppers were taken immediately to the state laboratory and were pronounced sterile, but the eye was lost in forty-eight hours. Examination of the purulent discharge showed a small rod-like bacillus of great activity which rapidly affected the culture-medium, but gave no intimation of the source of infection.

Case 94.—Male, aged 84 years, had the wound infected on the second day, and ten days later enucleation was done. This case was undoubtedly infected by the unclean fingers of the patient, as he tore the bandages from the eyes and rubbed them violently the first night and was so unruly that no covering could be kept on the eye.

Of the four cases resulting in perception of light two may be designated as accidents pure and simple.

Case 9, was a simple extraction of soft cataract. The operation was done in a boarding-house and the patient was on the third floor. During the night while the attendant was asleep he arose from the bed and went down the three flights of stairs to an out-house in the yard. Returning in apparent safety he miscounted the stairs and turned into the room on the second floor just under his own, and groping his way he deliberately crawled into bed with a man and his wife. Aroused from sound sleep by this unwelcome intruder the occupant of the room seized the patient by the collar, marched him to the door and calmly kicked him downstairs. The next morning I found the wound open and a large hernia of the vitreous. Recovery was slow but without useful vision.

Case 26.—On the seventh day while making an uneventful recovery, a fly crawled into the nose of the patient and caused a violent attack of sneezing. The wound was opened with loss of vitreous and a resulting iridocyclitis, which resulted in a blocked pupil and although two attempts were made to improve the vision by discission and an iridotomy the result was not favorable.

In Cases 20 and 60, iritis of a severe type on the fifth and sixth day produced a tedious convalescence and blocked pupil.

Case 91.—Male, 69 years of age, was referred to me by another oculist with a request that I operate on him in the hospital. The patient was not seen until on the table, when I found a large fleshy pterygium on the cataractous eye. Although my judgment was against operating, I finally did so, making the corneal section somewhat obliquely so as to avoid the pterygium. A severe keratoiritis developed and the ultimate vision was for large objects.

Case 88, was a hospital patient of exceedingly filthy habits, and there was an infected wound. Hot fomentations and the persistent use of pyoktanin checked the destructive process so that the eye was saved, but without useful vision.

Similar infection of the wound occurred in two other cases, one in private and one in hospital practice: The first was infected by the finger of the patient on the tenth day and, although the wound was infiltrated and the cornea like ground-glass, faithful and persistent use of hot fomentations and pyoktanin finally controlled the process and gave an ultimate vision of 0.8. The second case was infected on the fifth day and the vision for a week reduced to bare perception of light. Under the same treatment the vision finally gained was 0.6. Various minor accidents occurred which were annoying to both patient and operator, but did not materially affect the ultimate vision.

From a careful study of these cases and from experience gained in my first hundred operations on the lens, while perhaps not befitting me to give advice to others, I am able to draw the following conclusions which will at any rate guide me in future operative work:

1. More attention should be paid to the general condition of the patient, and the presence of any systemic disturbance should influence the prognosis.
2. All operative procedures on the crystalline body should be done under the best possible illumination.
3. Providing that it is large enough, the exact site of the corneal section does not materially influence the result.
4. The combined operation is the safest and the easiest for the operator of limited experience.
5. The most frequent complications, iritis and iridocyclitis, should be combated by the early instillation of atropin, and their existence does not necessarily prevent an ultimate good result.
6. Discission of the capsule can be done with comparative safety and materially increases the acuity of vision.
7. Infection of the wound does not in all cases destroy the sight, and careful and assiduous treatment may save an apparently doomed eye.
8. The experience gained in the first series of operations has, besides improving the technique of operation, impressed me profoundly with the possible dangers which may arise and will prevent me from advising operative procedures so freely as I have done in the past without a frank statement to the patient of the possible outcome.
9. For some reason, which I hope will be brought out in the discussion, I have had more iritis in these cases than I should, but whether due to defective skill in operating or insufficient care in the after-treatment I am unable to decide.

DISCUSSION.

Dr. E. E. Holt, Portland—I have been very much interested in this paper and I think we should all welcome reports of cases carefully taken down and the deductions made from them. When I began practice 25 years ago I found no satisfactory book for making records of eye cases and I devised one so that I could have a record of all cases, but I have made but few compilations therefrom, which is contrary to the resolve I made early in my practice. When I mention, however, that I have founded an eye and ear institution and begged and handled several hundred thousand dollars to build it and carry it on I think you will excuse me. I find, however, that in the records of the Maine Eye and Ear Infirmary I have operated some 500 times for cataract and in my private practice I think I have done as many more, so my experience is based on about a thousand operations for cataract.

In opening the discussion on this paper I am reminded that in the American Ophthalmological Society, when we have listened to a paper on cataract, it is passed by without discussion because members say there is so much to be said and no one is willing to undertake to start it. I shall confine my remarks to my personal experience.

In the preparation of a case for cataract operation I like to get acquainted with the patient and have him under observation at least a week before I operate, see that the bowels are all right and have him take certain baths and remedies that may be indicated. I have the face washed and all parts adjoining the face cleansed in bichlorid, and the conjunctival cul-de-sac washed out with a 1 to 5000 solution of bichlorid for a week or more before operation. I also look after the lachrymal sac, syringe it out with antiseptic solutions if need be, and examine the nasal cavity and mouth to remove all possible foci of infection. I like to use some weak mydriatic in order to examine the lens, to estimate its size and determine as well as I can how large a corneal section I shall make. I admit this is very difficult to determine in some cases, as we find some larger lenses than we anticipate. In my early career I operated with ether and did the modified Graefe operation with an iridectomy. For the last ten years or more, however, I have done the simple operation without iridectomy as a rule.

making the puncture and counter-puncture just at the corneal margin, and I like to make a small conjunctival flap, for I think I am less likely to get prolapse of the iris. In changing over from operating with iridectomy to operating without it I found that I had to learn a new technique, and one of the most essential points to observe is, after making the cystotomy, to make pressure on the lower border of the lens to tip the upper part forward and prevent its sliding up under the iris. In my early career I always practiced on the mask with pig's eyes before attempting an operation, and I think that it is very important for the young operator. I am sure I performed more than a thousand operations on pigs' eyes before I did many cataract operations on the human eye. The young man has plenty of time to do it and it gives him confidence in his hand and forearm, and when he has to operate he will do the operation very much better. I was very much pleased some time ago when I saw a book written on that subject, though I can not recall at this moment the name of the writer.

I used to wash the anterior chamber out when there was any amount of cortex left. I should not hesitate to do that now, although I think there is apt to be some irritation from it, but I do not find the occasion for it as I used to. I think the normal-salt solution sterilized is better than the pure water for this purpose. In dressing the eye I have for a long time been putting cotton over the eye and using isinglass plaster to hold it in place. Fifteen years or so ago I used a shield made of wire and also of pasteboard, but I abandoned them, for in my practice I thought I got more prolapses of the iris when I used them than when I did not. They are apt to become irritating to the patients and they make efforts to move about, causing spasms of the muscles, and, by the way, I think prolapse of the iris is more frequently caused by muscular contractions and spasms than by external violence.

When Dr. Ring brought out his eye shields I tried them, but I again abandoned them for the same reason I had before.

Dr. R. L. Randolph, Baltimore—I hope this paper will elicit some discussion as to the technique to be pursued in these cases. I have long maintained that the eye is endowed with natural powers that make it unnecessary to use bichlorid douches before the operation. While I am not prepared to say that its use in Dr. Rogers' case had anything to do with the iritis, I do not think he would have had any more iritis if he had abandoned the use of the bichlorid. I think the eye, more than any other part of the body, is endowed with antibacterial properties, and I make it a rule to use no bichlorid solution whatever. In the first 100 cases I reported I did use it; in the second 100 cases reported a few years ago, I used nothing, but simply sterilized my instruments and used sterile cocain. I would like to ask Dr. Rogers if he sterilized his cocain in these cases.

I am surprised to note the number of cases where he was successful in maturing the cataract. I have tried in ten cases, but succeeded only in one. Lately, I have abandoned cocain also in these cases and never use anything but holocain.

Dr. W. B. Marple, New York—I should think it would be interesting in connection with Dr. Randolph's remarks to know from the different gentlemen here whether or not they irrigate the eye before operation. Since Dr. Randolph's paper of a few years ago, I have used nothing but the sterile salt solution, and I would like to know if there are many who use no irrigation at all. Irrigation with some sterile non-irritating solution seems to me to be in many respects of decided advantage.

Dr. Albert E. Bulson, Jr., Fort Wayne—Aside from the general interest which a paper on cataract operations excites, this paper becomes of interest because the essayist recounts his failures and successes, with reasons therefor.

The point which I wish to make in discussing the paper is that, with the average operator, a preliminary iridectomy is usually unwarranted. It has always appeared to me to be an unnecessary risk to open the eye twice for the purpose of removing an opaque lens. The average ophthalmologist does not exceed fifteen or twenty cataract operations a year, and as every one of these cases must of necessity carry its weight of praise and blame, and as it is practical results which all patients desire, it behooves the operator to secure the best possible results as a minimum risk. In spite of the most exacting efforts to have an aseptic operation, occasions will arise in which infection alters what otherwise might prove to be an ideal result, and opening the anterior chamber twice paves the way for such a complication. I have never felt that the results with preliminary iridectomy averaged any better than the results with iridectomy at the time of extraction, and the patient certainly objects to two operations when one may be fairly stated to do as well.

I believe the combined operation for the average ophthalmologist to be, not only the easiest, but the best for securing practical results. It is usually attended with fewer complications, and but few patients will complain of the cosmetic effect, the main desire being to get vision, and it is this which brings out their praise.

Dr. J. L. Thompson, Indianapolis—These reports appeal to most of us because there are very few of us now that see as many cases as Knapp, or the Baltimore physicians, and very, very few of us get more than twenty-five cataract operations a year. I feel that one of my failures used to be due to the manner in which I used the speculum. That seems to bother a good many of the beginners. I used to open it very widely, but now I open it just as little as possible, to give enough room to work on the eye. Of course, I began when there were no antiseptics in use. In regard to cleaning the wound, I notice, if you go to Knapp's clinic, for instance, the great pains he takes to clean the wound and to put the iris back just as carefully as possible, but the beginner feels that he had better leave well enough alone, and he does not want to work over the eye too much.

I do not recall one case I ever lost where I made a preliminary iridectomy. We have so many cases where just a plain extraction of the cataract is out of the question on account of the small cornea; the deeply sunken eye, the shallow anterior chamber, etc. I would like to advise the beginner to learn to use both hands and to do an iridectomy.

Dr. Lucien Howe, Buffalo—I want to call attention to one point in regard to the difficulties with an assistant, and the necessity of having some one who rotates the eye or fixes it without pressing on it. Some years ago I presented a small pair of autofixation forceps, and I want again to call your attention to the advantage of not having another brain to depend on, but in having one's own fingers only involved in the operation. The little forceps on the speculum fixes the eye perfectly, and acts as our third hand.

YELLOW FEVER; ITS NATURE AND CAUSE.*

EUGENE WASDIN, M.D.
Surgeon U. S. Marine-Hospital Service.
WASHINGTON, D.C.

From the earliest history of yellow fever in our country there have been evidences of its having been imported from some foreign place, usually the countries to the southward within the tropics. This importation has usually taken place during the prevalence of warm weather in the spring, summer or fall months, and could be traced to one of the intertropic endemic centers. During cold weather, the disease would disappear either entirely or to a great extent.

Its continued presence, however, from year to year in some of our southern cities, and its recrudescence with the advent of the warm weather of the spring, following its epidemic presence during the summer, induced numbers of prominent observers to believe that this disease was indigenous to our southern latitudes, and, like malarial infections, depended on unsanitary conditions.

The cessation of the fever following the institution of an adequate system of maritime quarantine protection for our southern seacoast cities, against such importation, was the convincing argument that is was essentially exotic. The continuance of an epidemic invasion of these latitudes depended invariably upon the continuance of heat and moisture, so much so, that close, humid and sultry weather became known as "yellow fever weather," for under such conditions the disease propagated more rapidly and became more fatal; while on the other hand, dry, temperate weather has been known to induce a cessation of the disease before the advent of colder weather. The appearance of the cold season has invariably been followed by a marked diminution in the number of cases at any center, endemic or epidemic; and those instances recorded of this disease, during cold weather, in temperate latitudes must have depended upon some special feature of exposure. As a matter of fact, they have been recorded in cities of the Northern States where the first hint of winter is sufficient to determine the almost perfect closing of houses against cold, and therefore, the enclosure of the specific organism in an atmosphere sufficiently warm to allow the propagation of the disease from person to person. In southern latitudes this barricade against frost is not nearly so complete, and it is not unusual for such communities to be caught unprepared for winter; within the infected homes, therefore, the germ is as much refrigerated as it would be out-of-doors. Isolated recrudescences, however, indicate that through special agencies the organism may pass safely through the season of frost, and produce the disease, under conditions of increased temperature. These deviations from the normal history of yellow fever are so infrequent that it is evident they depend upon such special influences.

---

*Presented to the Section on Practice of Medicine, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Within the tropics the disease is endemic under similar atmospheric conditions to those which determine its epidemicity, i. e., heat, moisture and unsanitary environment, the presence of témoines contributing to its endemic duration. In such centers the advent of cold weather, scarcely ever so frosty as 40 F., is followed by a notable cessation of yellow fever; and it is a clinical fact that during such seasons of cessation, as in the city of Havana, the cases which do occur are well marked and frequently have a fatal termination.

Such is the natural history of this scourge of the tropics, bête-noire of the southern states contiguous to them; it is that of an acute infectious malady, dependent upon an etiologic entity which exhibits a marked susceptibility to changes of temperature, this susceptibility finally causing the disappearance of the disease.

Yellow fever has also presented a uniform complex of symptoms which has served to distinguish it clinically from the other infections. Its onset may be either precipitate, or heralded by a series of prodromes such as are common to these infections. The course and termination of the disease do not seem to be in direct sequence to the onset; the precipitate cases becoming benign, and the mild onset frequently followed by the gravest symptoms.

In a characteristic case the temperature rises to its maximum within the first twenty-four to thirty-six hours; the pulse rising at first in proportion to the temperature. This, however, does not continue and there ensues a remarkable reduction of the pulse-rate, at the same time that the temperature continues to rise, or remains at its acme.

This is the first symptom in yellow fever that is of intrinsic value in the diagnosis of the disease. It was clinically recognized by early observers, but it was not until the introduction of the clinical thermometer enabled the elder Faget to accurately chart the temperature range, that this remarkable phenomenon was fully recognized to be of diagnostic importance. Faget established *avec l'aide de la montre et du thermomètre* the law of the non-correlation of the pulse and temperature, and it has been recognized, by all conversant with the disease, as of inestimable value in its diagnosis.

The prodromal symptoms of the infection, such as cephalalgia, rachialgia, pain in the eyeballs, the slight yellowing of the conjunctiva and scleræ, can be of only slight differential value. However, with the undoubted presence on the clinical chart of the phenomenon of Faget, the case assumes a more serious aspect, and the diagnosis will probably be confirmed by the later symptoms.

The next clinical feature of importance is also connected with the temperature chart. Upon the second or third day of the disease, it is usual for the temperature to decline, and there is a more or less marked remission, at times an intermission, of fever. There is no fixed time for the appearance of this fall in the temperature, but it is so confidently anticipated by clinicians of epidemic and endemic centers, that its non-appearance has often caused them to diagnose the malady as an infection of an allied nature.

The fall in temperature may be of one or two degrees, or it may reach the normal, or pass below it. Under all circumstances it is accompanied by a notable alleviation of the distressing symptoms, the patient entering a period of comparative calm, which may last from one to many hours. Indeed, it is possible that convalescence may be established at this stage, but in the characteristic type under consideration it is soon followed by an exacerbation of the temperature, which may rise even higher than during the "first paroxysm," and an exaggeration of other symptoms. The patient enters now upon the "third stage" of the disease, or into the "second paroxysm" of the fever, the paroxysms being separated by the "period of calm," or "second stage" of the disease.

This phenomenon presenting the two accessions of temperature, with a decline, the period of calm, separating them, has been recognized by southern clinicians as the most characteristic of all the symptoms of yellow fever; and it may be recognized, as outlined here, in all cases lasting from three to eight days. These variations of the temperature forming the three periods, or stages, of the fever have heretofore been regarded as inexplicable from a clinical standpoint, although many clinicians have advanced theories which did not satisfactorily account for them.

Among the clinical phenomena should be mentioned the "black vomit" encountered in this disease with such constancy as to name the disease in some countries "*vomito negro;*" also that phenomenon encountered postmortem, the extreme steatosis of the liver cells, which transforms the organ into a friable, yellow tissue incapable of performing its functions, and from which arises the icterus, or yellow skin, giving the well-known name to the disease. Other organs are involved but in them there is no special change characteristic of the malady.

Cases of yellow fever have been divided into three classes or varieties, the ephemeral, the grave, and the *siderante* or fulminantly fatal cases. The first class comprises cases exhibiting a slight toxic attack, ending in recovery in from two to three days or less. They are with difficulty diagnosed because of their resemblance to other infections of less gravity, and have been likened to a "slight cold." To this class belong the acclimatization fevers of the tropics. The second class embraces all grave cases of the type already described as presenting the characteristic symptoms. The third class are those rapidly fatal cases in which death ensues before the appearance of many of the characteristic symptoms, but in which acute fatty degeneration of the liver is always found, together with a most pronounced paralysis of the vasomotor constrictors, as evidenced in the marked visceral congestions and the intravisceral hemorrhages. These are the clinical and pathologic peculiarities which, with the natural peculiarity of the disease mentioned above, must be correlated with the phenomenal powers of the organisms said to be the cause of the disease.

THE CAUSE OF THE DISEASE.

Since the bacterial origin of yellow fever became a probability through the discoveries of Koch, Fränkel, Löffler, Eberth and others in the domain of the acute infections, there have been numerous organisms announced as its cause. In 1885 Domingo Freire, of Brazil, and Carmona y Valle, of Mexico, announced the discovery of the infecting organism, and in 1887 two announcements were made from Havana, by Finlay and Gibier, who isolated totally dissimilar organisms from the cadavers of yellow-fever patients.

The proofs advanced in support of these claims were not convincing, and during 1888-9 the question was thoroughly investigated by Dr. G. M. Sternberg, of the army medical corps, who was detailed to this duty through the Surgeon-General M. H. S. His report[1] was made in 1890, in which he stated, after careful and exhaustive research into the merits of these claims, that "among the micro-organisms encountered there is not one which, by its constant presence and special pathogenic power, can be shown to be the specific cause of the disease," and further, that with the most approved facilities at his command he had not been able to discover an organism in the blood of those ill from yellow fever, and expressed the decided opinion that the infectious germ, if a bacterium, would require for its detection other aids than those which he had employed. Incidentally, he suggested the possible etiologic value of his bacillus "X," isolated at Havana, since it had proved pathogenic to animals, with the production of the morbid anatomy found in men dead from the disease.

These observations of Sternberg made a profound impression on the professional mind of this country, and, without doubt, acted as a deterrent to further investigation. Indeed, I recall the personally stated opinion of one of the most distinguished bacteriologists of the day, that the disease, in view of that report, was scarcely one of bacterial origin, but that the cause might be a plasmodium, and he suggested freezing the bodies of victims of this disease, immediately after death, in order that section might disclose the pathologic conditions unchanged, and possibly also the infecting cause. When, in 1897, Giuseppe Sanarelli published the account of his work in yellow fever[2], there at once arose a murmur of surprise and incredulity, so fully had our minds been imbued with the value of the statements made by Sternberg in 1890. Dr. Sternberg himself at once assumed the defensive, and antagonized the statements of Sanarelli as casting reflections upon his own work, and he insisted upon the identity of his bacillus "X" and the bacillus icteroides, assumed by Sanarelli to the cause of yellow fever.

This was the state of affairs when the epidemic outbreak of the disease in Mississippi and Louisiana in the fall of '97 enabled the Surgeon-General of the Marine-Hospital Service to detail officers from his own corps to investigate its etiology. For this purpose he detailed P. A. Surgeon H. D. Geddings and myself to the isolation hospital of the city of New Orleans, and later, at the direction of the President, to Havana, Cuba.

The results of the work of that commission were embodied in a report[3] to the President through our Surgeon-General, dated July, 1899. The conclusions arrived at by the commission, as therein stated, are as follows:

1. That the micro-organism discovered by Prof. Giuseppe Sanarelli, of the University of Bologna, Italy, and by him named "bacillus icteroides," is the cause of yellow fever.
2. That yellow fever is naturally infectious to certain animals, the degree varying with the species; that in some of the rodents local infection is very quickly followed by blood infection, and that, while in dogs and rabbits there is no evidence of this subsequent invasion of the blood, monkeys react to the infection the same as man.
3. That infection takes place by way of the respiratory tract, the *primary colonization in this tract giving rise to the* earlier manifestations of the disease.
4. That in many cases of the disease, probably a majority, the primary infection or colonization in the lungs is followed by a "secondary infection," or a secondary colonization of this organism in the blood of the patient. This secondary infection may be complicated by the coinstantaneous passage of other organisms into the blood, or this complication may arise during the last hours of life.
5. There is no evidence to support the theory advanced by Professor Sanarelli that this disease is primarily a septicemia, inasmuch as cases do occur in which the bacillus icteroides can not be found in the blood, or organs in which it might be deposited therefrom.
6. That there exists no causal relationship between the bacillus "X" of Sternberg and this highly infectious disease; and that this bacillus, "X," is frequently found in the intestinal content of normal animals and of man, as well as in the urine and the bronchial secretion.
7. That, so far as your commission is aware, the bacillus icteroides has never been found in any body other than of one infected with yellow fever; and that whatever may be the cultural similarities between this and other micro-organisms, it is characterized by a specificity which is distinctive.
8. That the bacillus icteroides is very susceptible to the influences injurious to bacterial life, and that its ready control by the processes of disinfection, chemical and mechanical, is assured.
9. That the bacillus icteroides produces *in vitro* as well as *in vitam*, a toxin of the most marked potency; and that, from our present knowledge, there exists a reasonable possibility of the ultimate production of an antiserum more potent than that of Professor Sanarelli.

Does the bacillus icteroides, therefore, fulfil the demands of modern bacteriology; and does it offer an explanation of the clinical and natural history of yellow fever?

In the report of 1899 the Commission affirms the isolation of this bacillus from the blood of 13 of 14 patients in whom the disease was clearly recognized, that is to say, in whom the typical phenomena of the disease were present, or in 92.85 per cent.; in those dead from the disease it was isolated from the blood and organs in 85..7 per cent. Sanarelli had predicated his discovery of the cause of the fever upon the presence of the bacillus icteroides in about 55 per cent. of his cases living and dead[4].

Our cultures thus isolated were pure, and in no instance was a contaminated culture allowed to enter our computations. These cultures were each retained and are still in evidence. Introduced into animals susceptible to them, they each produced illness and death, the morbid anatomy being similar to that of man dead of the disease.

The organism is always [illegible]d i[illegible]se artifi[illegible] fections, as it is in the [illegible] in ma[illegible] tributed by the blood-c[illegible]

Moreover, the cl[illegible] an[illegible] troduced into animals [illegible] the ease, and furnish the pathologic changes peculiar to it. Sanarelli made use of the soluble toxins of the germ in an experiment carried out upon some nine imbeciles, otherwise healthy, who were under the care of a civic institution. Of these helpless ones nearly all reacted to the intravenous injections of the toxins; in a few there were evident signs of profound toxemia with symptoms of the disease; and in at least one case death must have ensued, the autopsic findings being those of yellow fever.

It would appear therefore that the bacillus icteroides would require no further proof of its pathogenicity; that its etiologic rôle is patent, since it has fulfilled the demands of bacteriology as laid down by Robert Koch.

After the Report of 1899, and just prior to its issue, there were a number of voices raised against the acceptance of the bacillus icteroides as the cause of yellow fever, mainly because of its close cultural relations to many other organisms known to be infectious in their nature[5]; and because of its behavior in the presence of changes of temperature[6].

Taking the experimental work of Sanarelli under consideration, during my work in Havana, I soon became convinced that he had fallen short of proving his position in regard to the etiology of the disease, and that the contention of Sternberg, in favor of the specific influence of bacillus "X," was a very valid one, since bacillus "X" was frequently isolated from the yellow-fever cadavers at our disposition, and at times from the living blood, and since this bacillus, and its toxin, acted upon animals in artificial infection in a manner strikingly like that of the bacillus icteroides. But Sternberg seemed to have lost faith in his organism, and withdrew it from further consideration before I had fully determined, by experimentation, its lack of specificity.

All that Sanarelli had proved in his mémoirs was the presence, in one-half of his cases, of an organism not before described in yellow fever; that it possessed powers pathogenic to animals by artificial infection; and that its toxins had proved toxic to man and animals, the lesions produced resembling those of yellow fever.

These facts were applicable to the peculiarly motile, highly pathogenic organism of the colon group, found freely by us in cases of the disease, and which corresponded perfectly to Sternberg's bac. "X." I was therefore compelled to attempt a differentiation of these bacilli. They were both pathogenic in animals; were they infective to them also? Introduced into their tissues, or into their blood, the reactions were very similar; they produced acute sepsis, with a profound influence upon the vasomotor constrictors, the paresis of which was, in all cases, followed by intense congestion of the organs, especially the cavernous ones, in which lack of support tended to free hemorrhages, notably the stomach—"black vomit"—and the intestines—"black stools." The parenchyma of the organs suffered from fatty degenerations, and necrosis. The onset of symptoms and death seemed to be in direct ratio to the amount of culture injected; there could scarcely be determined any cycle of disease in the case of either organism.

The differentiation of the organisms could only be accomplished by a series of experiments with susceptible animals naturally exposed to their infective influence, and to do this I exposed white mice, susceptible to most infections, to bacillus icteroides, and bacillus "X," in pure culture, as well as to a common colon organism, and that of Havelberg, who had announced its discovery some time before. The same conditions were maintained for all the mice thus exposed, the organism being placed in their grain. In a given time—8 to 10 days—all the mice, 19 of them, exposed to the bacillus icteroides became infected, and all died except one, which recovered after a severe illness. Of those exposed to bacillus "X" not one sickened or died. Those exposed to bacillus coli communis, and to the bacillus of Havelberg remained perfectly well.

From those infected by bacillus icteroides, it was determined that its incubation took place within five days, the usual incubative period of yellow fever; and that its cycle was that of the septic type of the disease in man, or of 5 to 8 days' continuation. The autopsies in these cases were typical of those in man. Of other animals, guinea-pigs resisted the natural infection, which was a surprise in view of the active reaction of this rodent to artificial infection. Rabbits reacted readily to natural infection, and in case of death gave characteristic autopsies. They developed the fact, however, that in them the blood does not become invaded; that is, that the colony of bacillus icteroides remains entirely local to the lung tissue, and sepsis does not take place. Dogs react readily also to the inhalation of the bacillus icteroides, and are invincible to the germ placed in their food, or in the small intestine beyond the acid stomach. In them also there is no secondary invasion of the blood, absolutely no sepsis, the necropsies presenting typical pathological appearances. Monkeys are susceptible to the inhalations of bacillus icteroides, and present a picture of suffering from symptoms of yellow fever very similar to that of man. In this animal the secondary invasion of the blood on the third day of the disease was demonstrated by careful planting of minute quantities of blood daily from the commencement of the symptoms. There were no deaths in monkeys; all of those infected recovered.

Altogether 44 animals were subjected to the infective influence of the bacillus icteroides, exhibited naturally. Of these 34 reacted, showing acute symptoms of disease, and 23 died, a mortality of 67.5 per cent. Recoveries took place among dogs, white mice, rabbits and monkeys, which demonstrates that the domestic animals may enter as a factor in an epidemic of the disease.

During my experimental work we were honored by a visit, at our laboratory in Havana, from Dr. Sternberg, who said to me, while passing through our animal room, that the strongest argument against the acceptance of the specificity of any one of the organisms advanced as the cause of yellow fever, was the fact that no one of them, during experiments in laboratory, had ever communicated this disease by natural infection to the animals of those laboratories; and he asserted that, whenever such infections should occur, the lesions being characteristic, and the organism recovered, he would accept that organism thus demonstrated as the cause of yellow fever, and such demonstration as the proof of its specificity.

In that same room, shortly afterward, I had nine cases of this disease occur among the animals, naturally caught, from the introduction into the atmosphere of the adjoining room, of the bacillus icteroides. Eight of these animals died; one recovered; from the necropsies I recovered the bacillus icteroides in pure culture from 50 per cent., almost as large a number of cases, and as large a percentage of isolations, as those used by Sanarelli in forming his assumption as to the value of bacillus icteroides in the etiology of the disease. These spontaneous infections occurred in dogs, mice, guinea-pigs and rabbits. The first infection, that of rabbit "S. S," was noticed on April 16, 1899, the only known exposure being that of the insufflation of dog "A," in the adjoining room, on April 7, with the bacillus icteroides in lycopodium powder. Granting 3 to 5 days as the incubating period of this bacillus, we have the disease lasting in this rabbit from 6 to 8 days, and ending in death on the seventeenth. In all these animals the disease was accompanied in the pregnant female by miscarriage, and in the normal female by flooding. Necropsies gave the characteristic morbid anatomy of yellow fever.

I therefore maintain that Sternberg, who has assumed the rôle of censor in this disease, should now be thoroughly convinced, since my work has been crowned with the results which he demanded, and since our commission has proved what Sanarelli did not, that the bacillus icteroides is constantly present in yellow fever, and is the cause of the disease. Sanarelli, in a recent issue of the *Medical News*,[7] has acknowledged the work of the American Commission, as a confirmation of his own, and he uses its results in formulating several conclusions which were not possible with the information derived from his experience alone.

But the work of that commission was far more important than this. It constitutes the only proof of the specificity of the bacillus icteroides, and without such demonstration the bacillus icteroides would have no better claim to our consideration as the cause of yellow fever than the organisms of Sternberg, Havelberg, or the commoner colons, that of an artificially pathogenic microbe.

The close cultural and biologic relationship which exists between bacillus icteroides and some others, infectious to animals, but not to man, as the micro-organism of American hog-cholera, the hog-cholera of Bavaria, that of the peripneumonia of calves, and that form of colon frequently isolated from the summer diarrhea of children, and also known in acute mucoenteritis epidemic among young pigs, has been noted for some years, and recently resulted in the assertion of one observer that the bacillus icteroides is of the hog-cholera group, and therefore of secondary importance if found in yellow fever in the septic stage. According to this observation the bacillus icteroides, when fed to our domestic pigs, gives rise to disease, and autopsy discloses the characteristic lesions of hog-cholera in their intestines.

This has not been my experience with the most virulent bacillus icteroides, for with a most perfect environment against possible contamination with the bacillus choleræ suis, I was unable to infect the hog in Havana with the icteroides, and later, under conditions equally free from suspicion of contamination with cholera suis, Geddings, upon a group of pigs and controls had a similar experience. *Bacillus icteroides in pure culture, and in an* environment free from bacillus choleræ suis, does not produce hog-cholera.

When the observations noted above were called to my attention they interested me greatly, not that the conclusion arrived at by the observer was thought to be correct, but the question at once arose in my mind of the possible mutations of these specific organisms with changing environment. Could it be possible for bacillus icteroides to give rise to yellow fever in man and to cholera in the hog? Could environment thus influence results? In so far these observations were of immense interest, but my experience and those of Geddings seemed to properly dispose of the question, and to determine that, however closely allied these organisms might be, the specificity of each one seemed an inherent quality, to be developed under certain environment, and that this quality is immutable. The same observer has questioned the power of bacillus icteroides, as known in the laboratories of the milder latitudes, to produce constant toxic results, advancing its failure to produce "fatty degeneration" of the liver, when injected under such conditions, as an argument against its specificity. As a matter of fact, the bacillus icteroides, like many other infective pathogens, exhibits at times a most marked quality of septicity, and in proportion as the organism is septic it loses its toxic quality, and consequently the manifestations of toxicity, the fatty liver and renal epithelium, become merged into a condition characteristic of sepsis; that is to say, these organs present then more the appearance of the changes of typhoid fever, with necroses of their parenchyma rather than fatty degeneration. The more acute the intoxication in this disease, typified in the siderant cases, the more typical the fatty degenerations, and the reverse is equally true. We therefore can not expect the same results from this bacillus under conditions which we know will cause its attenuation, as those which we encounter constantly under conditions most favorable to the development of its peculiar powers. An instance in man—cited in the report of the commission,[8] that of Private Patrick Smith, 8th Infantry U. S. Army, who died of yellow fever at Havana, after an illness of nine days—presented a condition of sepsis or blood invasion by the bacillus icteroides, the most marked that I have ever known. His necropsy revealed a chronic malarial cachexia, upon which a pronounced anemia had depended, and modified changes in the stomach, the intestine and the liver; these modified changes, partaking of the nature of typhoid sepsis, were accepted by some of the attending physicians as diagnostic of typhoid fever, but evidently there was lacking an adequate conception of the quality of septicity in the bacillus icteroides, from which had arisen these modified changes.

There has been made one other, and apparently the most formidable, argument against the bacillus icteroides as the cause of yellow fever. Novy has shown that the bacillus was not killed by exposure to temperatures below the zero mark, but that after such exposures it gave rise to a septic condition when injected into animals. He therefore concluded that the bacillus could have no etiologic relation with this disease, since epidemics of yellow fever have always subsided and disappeared upon the advent of a temperature of the frost-line, or about 40 Fahrenheit.

Having had no experience with this bacillus under other than tropic and semitropic conditions of temperature, I could make no comment at the time of his publication, but at this time I can say that his position was only apparently well taken, *for the bacillus icteroides*, although not killed by exposure to extreme cold, is most profoundly influenced by temperatures at and below 40 Fahrenheit. Having had the opportunity during the past fall and winter months to observe these conditions, I tested carefully the facts of the case. While specially engaged at the Institut Pasteur, in Paris, in the matter of the possible production of a serum, curative and preventive, in this disease, I made a series of vaccinations in animals with the "sérum anticoli," of M. Lesage, and with the "serum antipneumoniæ in calves," of M. Fehrenbach, against virulent cultures of the bacillus icteroides which I had taken with me. Details of these observations are in the addendum.

During the months of September and October these serums seemed to afford but little if any protection to the animals used, vaccinées and controls dying nearly at the same time. With the advent of the colder weather, however, it was noted that the serums were more potent and now protected the animals, but at the same time it was noticed that the controls, inoculated subcutaneously, did not succumb, the points of inoculation presenting nodules of accumulated leucocytes, something unusual in my experience with the germ in the tropics. At this time I determined to test the influence of cold and heat upon the infecting quality of the germ, since cold had so materially attenuated its pathogenicity; for this purpose I exposed white mice to its infective influence at different degrees of temperature. From the same group of mice, six were selected and two were placed in each of three cages. In each cage there was placed grain mixed with an equal quantity of the same culture of bacillus icteroides, originally obtained from the blood of Patrick Smith, which had always proved extremely virulent. One cage was then placed in an incubator temperature of 25 C., or 77 F. One other was placed in laboratory room temperature of 18 C., or about 65 F., and the remaining cage in the open air in an outbuilding, one side of which was entirely open. The temperature in Paris during this outdoor exposure averaged 5 C., or about 40 F., and at times was below zero, ice and snow being present, the record of temperature having been taken from the daily Paris edition of the New York *Herald*.

In the cage at 77 F., one mouse become infected and died on the ninth day, about the usual period in these animals; and one died on the thirteenth day, much beyond the usual period of eight to ten days. In the cage placed at 65 F., one mouse died on the fourteenth day, and the other on the eighteenth day after exposure, or in twice the usual period of time. Two other mice, placed in a fourth cage and exposed to this temperature of 65 F., died on the nineteenth day after their exposure. In the cage placed in out-of-door temperature, the mice at no time, under daily examinations, gave the slightest evidence of disease, and when last examined, two months after their exposure, were perfectly well. To summarize, mice are extremely sensitive to the infection, developing acute septicemia, with death in all cases of my own except one. The mice exposed at summer temperature, 77 F., died in very nearly the time noted in the tropics. Those at 65 F. sickened and died, but at periods of twice the usual length in these animals. The mice exposed at and below 40 F., the "frost-line," with us, did not become infected and remained well. Details are given below. Beside this attenuation of the germ, as shown when inoculated into animals, I found that the attenuated germ does not produce a potent toxin, even when grown at 37 C.; for mice and pigs resist large quantities of the soluble toxin produced when injected into their tissues.

The bacillus icteroides was thus shown to attenuate rapidly in the presence of cold, losing its toxic, septic and specific qualities.

During the prevalence of extreme cold in Washington last winter, my confrère, Geddings, remarked that animals inoculated subcutaneously, and intravenously, with the bacillus icteroides, in order to revive the organism by its passage through them, failed to succumb to it, and as it was desirable to employ the most virulent germ in his work, he was nonplussed. At this time, in a note from Paris, I stated my observation in regard to the influence of cold upon the bacillus icteroides, when, acting upon this information, he placed the inoculated animals at incubator temperatures, with the result that they succumbed and furnished the virulent organism desired. Nothing can be clearer than this demonstration, and it is in consonance with the many different results obtained by observers in different latitudes with this bacillus.

Reverting now to the natural history of yellow fever, I can most positively assert that the most striking of all of its natural phenomena, its endemic and epidemic cessation with the advent of cold, is thus readily explained by my discovery of this peculiar biological phenomenon while investigating the life history of the bacillus icteroides—the loss of its toxic, septic and specific qualities in the presence of a temperature below 5 C., or 40 F.

As to the clinical phenomenon of the "double paroxysm," separated by a more or less well marked interval, or "period of calm," I believe that this can be explained by the consideration of the mode of infection in yellow fever. It has long been conceded that the disease is air-borne and not water-borne; and because of the marked lesions of the liver and intestinal canal, the primary colony of the causative organism has been thought to be in the intestinal tract. Sanarelli but dimly realized the truth, and so did not profit by it. He assumed that the bacillus icteroides, entering the body, perhaps by way of the respiratory tract, in some occult manner reached the spleen, there to lay *perdu* until finally, late in the disease, it invaded the blood, producing with other organisms a "secondary sepsis."[9]

This is not true; my observations in the natural infections in animals limit the colony primarily to the respiratory tract. In dogs and rabbits it is totally limited to this tract, there being in them no invasion of the blood from the primary colony. In man and the monkey this secondary invasion takes place some time after the appearance of the symptoms of intoxication from the primary colony.

My observations, therefore, have convinced me that the bacillus icteroides is always first colonized at some portion of the respiratory tract; that the intoxication arising therefrom produces the early symptoms of the disease, the "first paroxysm" of the fever; that the injury sustained locally sooner or later permits the passage of the germ into the circulation, with those evidences of sepsis termed the "secondary paroxysm," which has been attributed by the earlier authors to an invasion, from the changed intestinal canal, of bacillus coli communis and other organisms; and that this secondary invasion is due to the development of an inherent quality in the bacillus icteroides, that of septicity.

The interval of calm is due to the profound impression of the commencement of this second intoxication, from the bacillus in the blood-stream, upon the nerve-centers. This depression, amounting to shock, sometimes ends in death, but if the patient rallies the temperature again rises and sepsis is shown by its chart. It is an uncertain quantity, this interval of calm between the two toxic periods, the first intoxication arising from the primary colony, the second from the lung colony plus the influence of the colony invading the blood; the first a pure toxemia, the second a septicemia.

Should death take place during this primary toxemia the body will be found to be sterile, Sanarelli agreeing with us that the *foudroyante* cases are sterile, excepting the local colony in the lungs, a fact which he did not realize.[10] This explanation correlates the three periods of the disease, the first intoxication lasting from 2 to 4 days, when, if septicity develops, the blood colony becomes a factor in the secondary, septic, or "third period," lasting from 3 to 5 days longer, the "period of calm" being of several hours' duration, or so slight as to barely merit the name. Thus, too, will be explained the three great varieties of yellow fever. Why should there be three varieties of this disease? Because this bacillus exhibits *par excellence* the dual qualities of toxicity and septicity; if the toxic property is alone developed after an infection, cases of the first and third variety are produced. That is to say, an intense toxemia, resulting in death, is the *siderante* or third type, while the multitude of benign or ephemeral cases, in which only a slight toxic result is noticed, constitutes the first variety. Between these are possibly the majority of cases of diagnosed yellow fever of the second variety, those giving the marked clinical peculiarities mentioned above, and in all there is the phenomenon of the "second paroxysm," "septic invasion," or "third stage" of this peculiar disease.

In regard to the want of correlation between the pulse and temperature I can quote Dr. Bernard E. Baker,[11] of Charleston, as noting this phenomenon as due to the soluble toxins of the bacillus icteroides.

In regard to the role which domestic animals and vermin encountered in domiciles may play in the retention of yellow fever in their systems after their infection on shipboard, or during the prevalence of the disease on land, and its convection by this means to new areas, which may then become infected, I can but introduce the ready susceptibility of mice, dogs and rats to the infecting influence of the bacillus icteroides, and the marked reactions obtained by Sanarelli in his artificial infections, or inoculations, in the horse, in cattle, and in the ass. Domestic animals are therefore susceptible, and if infected, many of them may recover. In all of these the disease, as in man, is accompanied by intravisceral hemorrhages, and, except in the dog, in which there is no blood invasion, the dejecta, as well as any bronchial secretion, may contain the germ, from which the disease may recur in the infection of a resident of the domicile. This mode of entrance from shipboard and from house to house bears the aspect of improbability, but the well-known instances of this fact in the history of plague demand for it respectful consideration in connection with yellow fever. I am reminded also of the fact that during my stay in New Orleans in '97 and '98, I heard well-founded rumors of the presence of some disease at that time frequent among cattle and horses, which resembled epizootic, and which was attributed to yellow fever. I have not had an opportunity of subjecting the greater animals, horses and cattle, to the bacillus icteroides, and can not state the facts as to their natural reaction to the germ.

In at least one variety of animal extremely reactive to artificial infection, guinea-pigs, I have not succeeded in inducing a natural infection, although there was one case of natural infection among our animals, and this may apply to horses and cattle.

The danger from infection through animals, especially the rodents, has been illustrated on many occasions of yellow-fever outbreak at points ashore, and adjacent to the nearest landing place of such rodents swimming from an infected ship. Moreover, the recrudescences of the fever, even after quite cold winters, could be attributed to an attenuated form of the disease lasting among these animals during the cold months, and the propagation of the germ in virulent form with the advent of hot weather.

Such convection and propagation of yellow fever deserves the careful consideration of sanitarians in an equal degree as in bubonic plague. I therefore submit to your intelligent body these facts—elicited in my efforts to clear away the obscurities surrounding this American disease, and although it was the fortune of my friend, Dr. Sanarelli, to first see the germ and name it, it has remained for America, the United States, to furnish the indubitable proofs of the value of the Italian discovery, and further to establish the scientific explanation of this disease which more than any other has occupied our attention. Incidentally also to the establshment of the fact that the infecting pathogens vary in their pathogenic results with the varying preponderance of their two great qualities of toxicity and septicity; and that a proper recognition of the latter will serve to elucidate a number of heretofore obscure problems incident to these infections.

ADDENDUM.

Experiments to test the value of certain serums, known to be protective against the specific organism from which they were produced, on the animals subjected to the influence of closely allied organisms.

The serums used were those termed "*anti-coli*," perfected by M. Lesage, of Paris, France, and the "anti-peripneumoniæ" of calves, perfected by M. Fehrenbach in the Institute Pasteur, and the organism the bacillus icteroides obtained from cases of yellow fever in Havana, Cuba.

Oct. 26—A full-grown guinea-pig was vaccinated with 2 c.c. serum *anti-coli*, and in 2 hours was given subcutaneously .25 c.c. of a 24-hour bouillon culture of bacilli icteroides. A control pig of the same size was given, under the skin, .25 c.c. of the same culture at the same time. Oct. 27, both pigs were ill. Oct. 30, the control was found dead. Oct. 31, the vaccinée was found dead. Autopsy gave hemorrhagic conditions and light colored livers, the blood contained the bacillus icteroides in large numbers.

Oct. 28, a large rabbit, 2000 grams, was given .25 c.c. of a bouillon culture of the bacillus icteroides, 72 hours old, in the ear vein, two hours after 4 c.c. of the *serum anti-coli* had been given in the other ear vein. A control of the same size was given .25 c.c. of the same culture by the ear vein. Oct. 30, both control and vaccinée were found dead.

Nov. 2, two large guinea-pigs were vaccinated on four successive days with 1 c.c. of *serum anti-coli*. On the fourth day they were also inoculated with .5 c.c. bouillon culture of the bacillus icteroides, 72 hours old. Two controls of the same weight were given only the .5 c.c. of the culture of bacillus icteroides.

Nov. 6, one vaccinée was dead, no autopsy. Nov. 7, the control was dead, no autopsy. Nov. 8, the other control was dead, no autopsy. Nov. 11, the other vaccinée was dead, the autopsy showing that it had been dead some time. There was an ulceration of the skin at the site of the inoculation 2 cm. long by 1 wide, the peritoneum being laid bare, and covered by a cheesy layer of pus, the margins well defined. The abdominal incision was carried carefully around the ulcer and the peritoneum turned back exposing its inner surface at the site of ulceration. There was no peritonitis, the intestines retaining their brilliance. The outline of the ulcer was seen as a raised border of infiltration on the inner surface, and from this raised border I carefully made cultures on slant agar-agar. The liver was much engorged, with fatty and necrotic areas. The spleen was slightly enlarged. The stomach contained 50 c.c. of fluid containing black flakes of blood; its walls were congested and extravasation had taken place. The kidneys were congested; the heart was full of fluid blood. From all organs cultures were made and in forty-eight hours were sterile; the culture made from the inner surface of the peritoneum gave the bacillus icteroides in pure state.

Conclusion—The *serum anti-coli* appears to be protective to guinea-pigs to some degree. The first of this group to succumb was one of the vaccinées, yet the other vaccinée lived almost twice as long as the témoins, and presented after death a sterile interior. From the fact that these animals are most susceptible to the septic influence of this bacillus, it is clear that the *serum anti-coli* induced a local reaction at the seat of inoculation in this pig, sufficient to limit the organism to the seat of the injection and to prevent sepsis. The animal died of a toxemia from the localized colony.

Nov. 2 I inoculated a 2000-gram rabbit with 1 c.c. bouillon culture bacillus icteroides, 72 hours old, in the ear vein, and fifteen minutes afterward injected through the opposite vein 18 c.c. of the *serum anti-coli.* It died in 52 hours. At the same time, in another rabbit of the same weight, there was injected the same quantity of the bacillus icteroides, the "normal serum" of the horse being used instead of the serum anti-coli. This rabbit died in 74 hours. A control rabbit was also inoculated with the same quantity of bacillus icteroides alone. The control died in 65 hours. No autopsies were made except in the case of the first that died, the vaccinée with *serum anti-coli,* from which was regained the bacillus in pure culture.

Conclusion—There was no increase of resisting power from the vaccinations with the *serum anti-coli,* since this animal died first, the vaccin exerting a depressing effect at first similar to that known in the use of the "serum antipesteuse" for vaccinations. The horse serum did not exhibit this toxic influence and prolonged the life of the animal somewhat.

A large rabbit was vaccinated intravenously Nov. 11, with 10 c.c. of *serum anti-peripneumoniæ,* obtained from the sheep from subcutaneous injections of the killed cultures of the bacillus which causes this disease in these animals. Nov. 12, the animal was quite sick from this vaccination. Nov. 13, it was better, and 1 c.c. of a 24-hour bouillon culture of the bacillus icteroides was placed in the opposite ear vein. Nov. 15, there was some reaction; the animal was quite sick. Nov. 16, there was some reaction, the animal was still sick. Nov. 18, there was considerable reaction, the animal was quite thin. Nov. 22, it was better and gaining in weight. Nov. 25, there was given 10 drops of a virulent culture of the bacillus icteroides intraperitoneally. Nov. 27, it ate well and was gaining in weight; there was no reaction. Dec. 4, it was given .5 c.c. of a bouillon culture of the bacillus icteroides subcutaneously. Dec. 6, there was no reaction, and the animal seemed well, Dec. 14, the animal was found dead.

Autopsy showed meager body and under the pelt at the seat of the subcutaneous injection there was a solid lymph plaque 2 cm. by 1.5, from the center of which bouillon tubes were planted. The tissues were dry; the peritoneal cavity and its contents were normal; the liver normal in appearance; the spleen was the same; the kidneys were congested; the heart was full of fluid blood; serosæ normal; stomach and intestine normal. Cultures were made from all organs. On the sixteenth the cultures from liver and spleen and from the lymph plaque gave pure growths of the bacillus icteroides.

Conclusion—The vaccin *serum anti-peripneumoniæ* protected this animal against a dose usually fatal in 36 hours, but this protection was evanescent and the animal succumbed finally to a general invasion from the subcutaneous injection of the germ, on December 4.

Nov. 24, a large rabbit was vaccinated with 10 c.c. *serum anti-peripneumoniæ* in the ear vein. During the day it was dull, but not ill. On Nov. 25, it weighed 1960 grams, and the control 1980 grams. They were now injected in the opposite ear vein with 1 c.c. of the bacillus icteroides in bouillon 72 hours old. Nov. 26, the control was dead; Nov. 27, the original was dead; no autopsies were made, as they died of intoxication.

Nov. 21, five fine guinea-pigs were vaccinated with *serum anti-coli,* 1 c.c. being given daily under the skin for 6 days, or in all 6 c.c. were given to each animal. One received 8 c.c. altogether.

Nov. 21, each of these vaccinées received .5 c.c. of a bouillon culture of bacillus icteroides 48 hours old, a control pig receiving the same dose under the skin. Nov. 22, one vaccinée was dead from a perforation of the peritoneum into the abdominal cavity. Nov. 24, several vaccinées showed considerable local swelling at the site of the inoculation, the one to receive the 8 c.c. presenting the largest lump. This was perforated and the serum from it planted. Nov. 27, all the pigs appeared well, there having so far resulted only a local reaction. The planting from the localized swelling had resulted in a good growth of the bacillus icteroides. Dec. 1, these local swellings in vaccinées and controls were diminishing. Again I planted tubes from the serum obtained by puncture from them all. Also prepared cover-slips which showed the bacilli free and engulfed by the leucocytes. The tubes gave in 24 hours pure and active cultures of the bacillus icteroides. On Dec. 6, the experiment was finished; all the animals were well; the swellings having disappeared. Conclusion. There seemed no doubt that the serum had protected these pigs, yet the control had reacted to the inoculation to the same extent as the vaccinées. This was puzzling, but it was finally attributed to the influence of the very cold weather which had prevailed during the experiment, upon the bacillus icteroides.

On Nov. 27 three large guinea-pigs were vaccinated with 1.5 c.c., of the *serum anti-coli* subcutaneously, and this was repeated daily for ten days, each pig receiving 1.5 c.c. of the serum. On Dec. 5 these pigs were inoculated with 1 c.c. bouillon culture of the bac. icteroides, 36 hours old. Two controls were also given the same quantity of the same culture subcutaneously. On Dec. 10 all were apparently well, the vaccinées had developed a distinct tumefaction at the seat of inoculations, tending to suppuration. The controls had large tumefactions, hard, with sharp borders, and no pus. All were eating well and were playful. On Dec. 12, the vaccinées were purulent, the témoins hard, and sharp bordered at the site of the inoculations. At this time having become convinced of the attenuation of the bacillus by the prevalent cold, I placed the cage containing all these pigs in the incubator at 25 C, and removed them to the room temperature the next morning. On the 14th, the cage was again placed in the high temperature incubator. On the 15th, the control was found dead, the others remained permanently well in the room temperature, the vaccinées were purulent and the control was ulcerated at the site of the inoculations; all recovered. From this and the other results it was determined that it was useless to experiment further with these serums in view of the very evident attenuation of the bacillus icteroides by the cold, and all further effort was in the direction of proving the effect of cold and heat on this germ.

On Dec. 12, to test the quality of the soluble toxins of the germ, a bouillon culture in a Fehrnbach flask, 14 days old, was filtered to 5 c.c., and 1 c.c. was given intraperitoneally to a 500-gram pig without appreciable result. The remainder was tested against the highly toxic blood-serum of the eel and without result. It was considered the result of the attenuation of the germ. On Jan. 1, a 25-gram mouse was given .25 c.c. of the freshly filtered culture under the skin, the culture being 6 weeks old. In 15 minutes, there being no reaction, I gave 1 c.c. with no result; in all the mouse received 2 c.c. within the hour and without result.

On Jan. 4, I gave the pig which had received the toxins on Dec. 12, 2 c.c. of a bouillon culture of the bacillus icteroides, intraperitoneally; this culture had been made in a moderately warm temperature, from the bacilli obtained from the spleen of a mouse dead from natural infection after 19 days. There was no reaction. Therefore, it was evident that the bacillus was so changed by the prevalent cold that there was not the normal production of toxins, or that they were much attenuated.

On Dec. 12, in each of two sterile cages there were placed two white mice, and given grain inoculated with bac. icteroides, obtained through an African ape from one Patrick Smith. One cage was placed in a temperature of 18 C., and the other in an incubator at 25 C. On Dec. 21, a mouse in the warm cage was very ill; its mate seemed thin and ill. On Dec. 23, one was dead and the other was quite ill. All in the cold cage seemed well. On Dec. 27, the remaining mouse in the hot cage was dead. Autopsies were made on both. In the first the pelt was yellowish on its inner surface; the liver was friable, not fatty to the eye; the spleen was normal. The cultures from the spleen gave pure colonies of the bac. icteroides. In the second mouse the pelt was yellow; the liver somewhat fatty, and the spleen enlarged—something unusual; from it the bacillus was regained in pure culture. On this date all the mice at 18 C. were apparently well, and one of them was transferred to the hot cage. Dec. 30, this mouse was dead. On the same day, the remaining mouse in the colder cage at 18 C. was dead. *Conclusion*—While the elevated temperature of 25 C., induced infection and death in about the time usual in these animals in the tropics—8 to 10 days—the reduced temperature of 18 C. induced this infection and death only after twice the usual period, or in about 19 days.

On Dec. 29, two fresh mice were placed in one of the infected cages and 1 c.c. of fresh culture bac. icteroides added to their grain, the cage placed in the open air of the animal barn, one side of which was entirely open, the temperature that day averaging 11 C.

Dec. 30, Temp. 8.5 C. (average)	47.3 F.
Dec. 31, Temp. 8.7 C. (average)	47.4 F.
Jan. 1, Temp. 7.2 C. (average)	45 F.
Jan. 2, Temp. 9.5 C. (average)	49 F.
Jan. 3, Temp. 9 C. (average)	47 F.
Jan. 4, Temp. 7 C. (average)	44 F.
Jan. 5, Temp. 5 C. (average)	40 F.
Jan. 6, Temp. 5 C. (average)	41 F.
Jan. 7, Temp. 4.5 C. (average)	40 F.
Jan. 8, Temp. 4.5 C. (average)	40 F.
Jan. 9, Temp. 4.5 C. (average)	
Jan. 10, Temp. 4.7 C. (average)	
Jan. 11, Temp. 5 C. (average)	
Jan. 12, Temp. 4 C. (average)	
Jan. 13, Temp. 2 C. (average)	
Jan. 14, Temp. 2 C. (average)	
Jan. 15, Temp. 2 C. (average)	
Jan. 16, Temp. 3 C. (average)	
Jan. 17, Temp. 8 C. (average)	
Jan. 18, Temp. 7 C. (average)	
Jan. 19, Temp. 7 C. (average)	
Jan. 20, Temp. 6.5 C. (average)	

These give a general average of about 4.5 C., or 40 F., which is the frost-line, to which the animals were exposed without the appearance of any symptom of infection. At the end of this time the animals were transferred to a clean cage and the infected one was sterilized, the animals remaining well two months after the change.

At the same time, from January 5, two other mice were exposed to bacillus icteroides under the same conditions of temperature in the same barn until the 20th, an average of about 4.5 C., or 40 F., without the appearance of any symptom of infection. They were transferred to the clean cage with the other mice and remained permanently well.

These experiences demonstrate that the extreme degrees of cold, below the line of frost and approaching zero C., are extremely hurtful to the bacillus icteroides, attenuating it to such an extent that it failed to infect white mice, the most susceptible of animals, during an exposure of 23 days. Moreover, these are the only exposures of these animals which failed to result in infection in from 3 to 5 days at high temperature, and a longer period as the temperature became reduced.

DISCUSSION.

Dr. Simon Flexner, Philadelphia—I have been much interested in Dr. Wasdin's exhaustive paper. The high value of it is, of course, dear to everyone who has followed the literature of the subject since Sanarelli's discovery. Most bacteriologists believe that Sanarelli has done no more than point out the existence of a hitherto unknown pathogenic micro-organism in the bodies of a certain percentage of persons dead of yellow fever. The complete proof of its relation in a causative way to the disease is yet to be brought. This evidence, Dr. Wasdin thinks, is supplied by his experiments. He will, I am sure, permit a reasonable amount of scepticism even after his series of experiments. If we are to conclude that animals are subject to accidental infections with the bacillus icteroides, how are we to harmonize the absence of similar infections during the prevalence of the natural disease? Dr. Wasdin doubtless has established that the bacillus icteroides is capable of a high degree of potency; that its diminution in the air may lead to infection in animals; but I fail to see that by those experiments he has proved that he has produced yellow fever.

Dr. Gerry, Boston, Mass.—I should like to ask regarding the immunity of patients who have had yellow fever, if they really were immune. During the Cuban war we heard a great deal about the immune, and there seems to be a fixed idea that these people were really immune.

Dr. Eugene Wasdin, closing the discussion—The remarks of Dr. Flexner should carry much weight. It is certainly right to criticize, and I know of nothing that would be more productive of good. We feel convinced that further investigations will prove the value of the observations of Professor Sanarelli. In regard to the question of actual immunity from yellow fever I should like to have some one in the audience reply. I cannot do so. I can only state my own observations in the epidemics of yellow fever and what occurs in endemic centers. One attack does not protect absolutely against a second. I have seen several cases in which two attacks were enjoyed. There was black vomit freely ejected. The soldiers in Cuba supposed to be immune sometimes did suffer from a second attack. I regret that the time is so short that it will not permit me to go into details of the paper which would have been interesting and would satisfy some of the inquiring minds showing the amount of work condensed in the report of the commission made in 1899.

DEMONSTRATION OF HOME MILK MODIFIER.*

A. L. SHERMAN, M.D.

NEW YORK CITY.

The best food for an infant is its mother's milk; in its absence comes milk properly modified. Up to the present, this has been difficult of accomplishment. The Walker-Gordon Company has set a standard of what can be done in this direction, and now the Sheffield Farms Company, of New York, has opened a laboratory for the modification of milk. But such laboratories are situated in only a few of the larger cities, and their product is so expensive that their usefulness must necessarily be limited.

The modification of milk at home entails much elaborate calculation on the part of the physician; much patience and intelligence on the part of mother or nurse; methods so crude for the most part as to render the procedure difficult and inaccurate. However, although modified milk is acknowledged to be the best artificial food for an infant, it is comparatively little used.

The apparatus which I desire to demonstrate today is not intended to replace the laboratory, nor will it supply the needs of every infant. It will, however, if properly used, provide a food for any healthy infant for the entire first year of its life. It was suggested by Dr. Sidney V. Haas, of New York. This apparatus consists of a glass jar showing seven panels, with lip, capable of holding 16 ounces. One of [illegible] panels presents an ordinary ounce gra[illegible] panels [illegible] six different form[illegible] on of [illegible] each formula so arranged as to make it suitable for a certain period of the infant's growth, viz.:

---

* [illegible] [illegible]ases
Fifty-first [illegible]
held at A[illegible]

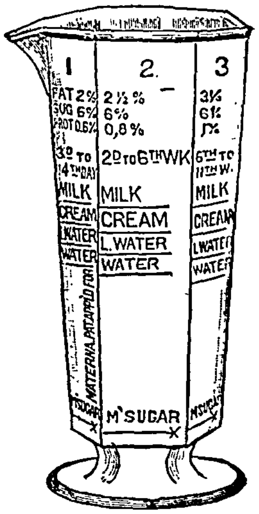
Formula	1	2	3	4	5		6
Fat, per cent.	2	2½	3	3	4		3½
Sugar, per cent.	6	6	6	8	7		3½
Proteids, per cent.	06	08	1	1½	2		2½
	3d to 14th day.	2d to 6th week.	6th to 11th week.	11th wk. to 5th month.	5th to 9th month.		9th to 12th month.
Milk, parts	1¼	1⅝	2	4½	6		
Cream, parts	1¼	1⅝	2	2	2	Milk, parts	9¾
Limewater, parts	1	1	¾	¾	¾	Cream, parts	1
Water, parts	12½	11¾	11¼	8¾	7¼	Barley gruel, parts	5¼
Milk sugar, parts	1	1	1	1	1¼	Granulated sugar, parts	¼

DIRECTIONS FOR FORMULAE 1-5.

The lines underneath the words indicate the points to which the various ingredients are to be filled in.

1. *Milk Sugar*—Introduce milk sugar to the line thus marked. Milk sugar is preferable, but where good milk sugar can not be obtained granulated sugar should be used, in just half the quantity. The small cross on the apparatus indicates the point for the latter emergency.

2. *Water*—Add boiled water (hot) to the water mark; stir until sugar is dissolved. If any particles are to be seen floating in the solution it should be filtered either through absorbent cotton, or a piece of clean muslin (two thicknesses).



3. *Limewater*—Ordinary limewater as bought in the drugstore should then be filled to the L. Water mark. (This is to overcome the acidity.)

4. *Cream*—This should be the ordinary cream, (16-20 per cent.) as obtained in bottled milk and as commonly delivered by the dairymen and should be filled to the cream mark. If cream is bought separately, the ordinary light cream should be used and never the very heavy cream.

5. *Milk*—Ordinary good cow's milk should be used and filled to the milk mark.

6. Stir the entire mixture.

7. The whole should then be poured into separate bottles and sterilized, or pasteurized if desired, and stoppered with cotton and placed immediately upon ice.

DIRECTIONS FOR FORMULA 6.

1. *Sugar*—In this formula granulated sugar should be used instead of milk sugar. Introduce the same into the vessel to the line thus marked.

2. *Barley-Gruel*—In this formula barley-gruel should be used instead of water and filled to the line thus marked. Barley-gruel should be prepared as follows: To one tablespoonful of pearl barley—after soaking several hours—add one pint of water, a pinch of salt, and boil for 5 or 6 hours, adding water as it boils away. Strain through muslin; or, one rounded tablespoonful of Robinson's barley flour; rub up with cold water, and add to one pint of boiling water; cook 15 minutes, stirring, and strain if lumpy.

3. *Cream*—Add the same as in other formulas.

4. *Milk*—Add the same as in other formulas.

5. *Stir*—Same as in other formulas.

6. *Sterilize*—Same as in other formulas.

The formulæ of the apparatus are calculated upon a 20 per cent. cream, and whole milk, *i. e.*, milk containing 4 per cent. of fat. Practically, however, the milk as obtained in bottles in the city will furnish the ingredients, the cream layer answering for the 20 per cent. cream, and the milk and cream left in the bottle shaken up together will supply the milk—a milk containing somewhat less than 4 per cent. of fat. Outside the cities where bottled milk is supplied, cream obtained in the usual way, by allowing it to rise in shallow vessels, and whole milk will answer.

Full directions and a schedule for the quantity of fat, the number of feedings, and the intervals between feedings accompany the apparatus.

SCHEDULE FOR FEEDING A HEALTHY CHILD DURING THE FIRST YEAR.

Formula	Age.	Number feedings in 24 hours.	Interval between feedings by day. hours.	No. night feedings 10 p.m. to 7 a.m.	Quantity for one feeding. oz.	Quantity for 42 hours' oz.
1	2 to 14 days.	10	2	2	1 to 2.5	10 to 25
2	2 to 5 weeks.	10	2	2	2 to 3.5	20 to 32
3	5 to 10 weeks	8	2.5	1	3 to 4.5	24 to 36
4	10 weeks to 4 months.	7	3	1	4 to 6	28 to 42
5	4 to 9 months	6	3	0	5 to 8	30 to 48
6	9 to 12 months.	5	3.5	0	7.5 to 9.5	37 to 48

A large child should receive the maximum quantity and sometimes even a little more; a small child should receive the smaller quantity and sometimes a little less. The hours for feeding should be kept conscientiously as indicated.

This apparatus is absolutely simple in its use. Nothing could be more accurate except the laboratory. It is capable of forming other percentages than those fixed by the combination of two of the formulæ. It is inexpensive. The modification is rapidly accomplished, and what is most important, it gives results. In those cases which have been under my observation in which this apparatus has been used there has been a steady gain in weight; the easy graduations by which the food is strengthened abbreviates entirely the gastrointestinal disturbance which is so apt to follow a change in an infant's diet.

If the following points are observed, the instrument can not fail: 1, fresh milk and cream of proper quality; 2, formula suitable to indvidual case; 3, quantity at each feeding suitable to individual case. In other words, this apparatus must be used as any drug is used. First the preparation is selected, then the proper dosage is prescribed.

Combined Wire Ligature and Vessel-Crusher.—Michaux announced a new method of hemostasis at the International Medical Congress which combines the advantages of a rapidly and easily applied ligature and of a vessel-crusher. The vessel is taken up on the female blade of the instrument, in which is fitted a U-shaped piece of silver wire. As the male blade closes on it, the ends of the wire are crossed and crushed to form a permanent ligature on the vessel, which is itself crushed at the same time. His experience with twelve major operations, including several amputations, has been extremely favorable.

THE REEFING OPERATION FOR MOVABLE KIDNEY.*

EDWARD WYLLYS ANDREWS, M.D.
PROFESSOR OF SURGERY, NORTHWESTERN UNIVERSITY.
CHICAGO.

It is well known that Hahn in 1881 first practiced nephrorrhaphy or nephropexy, since which time the operation has become a common one. The work done by Landau, Bruce Clark, Reidel, Tuffier, Guyon, Delvoie, Jaboulay and others, has reduced it to the class of procedures nearly free from risk in careful hands, and pretty sure to give relief in cases which require it. The mere presence of floating kidney is not an indication for operating. Some kidneys can be distinctly palpated which give no other symptoms; some which cause distress, are satisfactorily held by supporters. There has been much discussion as to what kind of supporter best retains a wandering kidney. A form of spring truss with a pneumatic pad always seemed to me mechanically more perfect than a belt or corset, inasmuch as the spring can push up under the costal arch in a way the belt can not imitate, just as the hand does in palpating and replacing the prolapsed organ.

Turning to operative treatment, we find also a somewhat unsatisfactory state of things in the frequency of relapses. It is true that a majority of cases of nephropexy remain cured or permanently benefited, and in so safe an operation a repetition is not a serious thing; but it would be still more satisfactory surgery if we could avoid all relapses and repetitions.

Hahn's first series of cases consisted of operations done by suturing the fatty capsule. A majority of these relapsed. He next included the fatty and the fibrous capsule in his stitches. In this method he had fair success. Out of 27 cases there were 15 cures, 4 improved, 7 relapsed, 1 died; total, 27.

Various operators—Riedel, Tuffier, Guyon, Nicoladoni—began to strip parts of fibrous capsule, after removing the fatty capsule, thus allowing the cortex of the kidney and the everted flaps of fibrous capsule to form a firmer union to the fascia lumborum. Suture of the parenchyma, in addition to free dissection of the fatty and fibrous capsule, is advocated by most recent writers, with the exception of a few who believe this endangers the kidney.

Jaboulay avoided sutures, and relied upon iodoform gauze packing to support the kidney in position until granulation tissue had formed around it to bind it in its bed. Senn advocates this method, and passes one loop of the gauze packing around the lower pole to insure its retention high up in the wound.

I have operated on a number of wandering kidneys, several of them double operations, and mostly by the older method of removing the posterior part of the fatty capsule and thus uncovering the fibrous capsule. This I formerly split into two flaps, which were everted and stitched to the muscles. Two long catgut stitches were then passed deeply through the kidney substance and out through the muscles. The muscles themselves were closed with buried sutures, and the deep sutures in the kidney substance tightened last of all. I am decidedly of the opinion that the stitches in the parenchyma cut through if drawn hard. In fact, I have seen this occur at the moment of tying.

I have usually sealed these wounds without drainage, and have had aseptic results; but in one instance a hematoma formed, which was slowly absorbed, and which was the cause of a partial relapse, probably by pushing the kidney forward and so preventing union with the posterior fascia.

On the whole, nephropexy by this method gives fair satisfaction. No dangerous symptoms have ever followed the operation in my experience, and it has always proved easy of execution. About 25 per cent. of relapses certainly followed, but in no case has the kidney been as movable as before, nor the pain as severe. This corresponds with the statistics collected by Delvoie, Keen, Langenbuch, and others, as follows:

	Cases.	Improved.	Cures.	Relapses.	Deaths.
Frank found in	39	. . . . . .	21	18	0
Keen found in.	59	. . . . . .	39	20	0
Sulzer found in.	93	10	56(?)	31(?)	3
Devoie found in.	215	30	135	45	5

Classifying according to type of operation, we have as follows:

	Cured.	Improved.	Relapsed or failed.	Died.
Suture fatty capsule.	4	3	7	0
Suture fibrous capsule.	10	3	9	2
Suture parenchyma.	75	14	19	2
Suture parenchyma capsule stripped.	9	0	1	0
Special methods.	37	10	9	1
	135	30	45	5

Before describing the new method, a few words by way of explanation may be in place. A fact that has been emphasized to me many times in operating on the kidney is that it is normally a very movable organ. As seen in the operation field, it is never at rest, but rises and falls with respiration, making a descent of about one inch with each excursion of the diaphragm. What happens now when we suture it tightly to the muscles? This rhythmic motion the organ shares with the other viscera below the diaphragm. That is, the liver, spleen, stomach and transverse colon, and kidneys rise and fall *en bloc*, or in unison. It is perfectly clear that, as the right kidney lies with its upper pole in a hollow made for it in the lower surface of the liver, a collision must take place between these two organs if the kidney is fixed artificially. In other words, the liver must thump or strike against the motionless kidney with each inspiration. Furthermore, as to the anterior ligaments of the kidney, the attachments to the other viscera are less firm, but they all have to do with holding the kidney in place or out of place. In case of enteroptosis and gastroptosis, I believe the kidney is dragged down, and its prolapse is entirely secondary. If we could palpate all the other viscera as certainly as the kidney, we should think less of the latter as a cause of the digestive trouble. Many patients with dilated stomach and enteroptosis refer all their pain and gastralgia to the misplaced kidney, which they can so easily feel with the hand, and think that if it were only kept in place the abdominal troubles would be gone. They seek an operation, and may be disappointed wholly or in part, because the sutured kidney can not bear the strain of supporting all the viscera. It must pull down under their dragging weight to some extent. Some nervous women would be better off if they never had been told that they had a "floating kidney." I should consider such a condition curable only by a combined operation on the viscera and kidney, or kidneys. The slighter respiratory excursion which the organ makes, is different only in degree from that of movable kidney. It would seem that when we endea [illegible] cure th [illegible] ation, we ought to le [illegible] d de [illegible] to do this is a difficult mechanical problem. The fascia near the vertebral column and twelfth rib is very rigid and strong, as are the deep muscles, like the quadratus lumborum.

---

*Read before the Chicago Surgical Society, April, 1900.

I now wish to call your attention to the fatty capsule, or capsula fibro-adiposa, and Gerota's capsule in front of it. We have seen that this structure was used by the first operators, like Hahn, in 1881, to hold the sutures in nephrorrhaphy. As already stated, this proved too weak a tissue, and out of 14 cases reported, 7, or 50 per cent., failed or relapsed. This was doubtless due to the inability of this layer to hold sutures properly. Nevertheless, I have found that I could always seize the fatty capsule of a prolapsed kidney, pull the organ up by it, and hold it firmly in the wound as long as I needed. This came about in the following manner: I have usually split this fatty envelope longitudinally, and thus formed of it two flaps, each of which I cut off, so as to bare the posterior surface. Now, in doing this I was each time more impressed with the complete control these flaps gave of the kidney. With these held by an assistant, the organ can be pulled firmly into the wound and held there much better than by pressure of the hand in front. I have several times had these flaps laid outward on the skin on each side, temporarily, to fix the organ, while I was splitting and sewing the fibrous capsule, as in Fig. 1.

It was also noticed that the respiratory movement continued however tightly the fatty sac was drawn, which was in direct contrast with what is seen when the fibrous capsule is sewn. The fibroadipose capsule contains in fact a reticule of fibers, forming a complete pouch for the kidney, in which it has free room to move. It reminds me of nothing so much as the dartos of the scrotum, having considerable strength of an elastic kind, yet allowing a free gliding movement of its contents.

Now, while the fatty, fibrous kidney capsule is not strong enough to hold stitches well, it occurred to me that it was strong enough to hold far more than the weight of the kidney, if its whole sac-like character could be utilized. This I have tried to do by an operation of gathering it together posterior to the kidney, and pulling it out through the lips of the wound. In dissecting this layer off the posterior wall, as in the older operations, I had often noticed that this fatty capsule was voluminous, and that the kidney was drawn fully up only when the former was well outside. It was therefore evident that it must be shortened, but still the problem remained of how to attach such a frail structure in which stitches could get no firm hold. It seemed that all attempts to use it were likely to end, as Hahn's original efforts had, in frequent relapses. I found, however, that by one method I could support it in the wound without tearing it. This was by gently holding it in the incision while the latter was closed with deep and superficial stitches. Thus the lips of the wound closed on it with a uniform pressure, and did not tend to cut it as sutures alone would do.

After perfecting this method as well as I could, I found that the *atmosphère cellulo-grassieuse,* as this layer is called by the French writers, has been used by Doyen, in 1898-99, in what he calls his hammock operation, the fatty capsule being shortened, and slung by stitches to the lumbar fascia and sometimes the twelfth rib. This seems like a return to Hahn's unsuccessful method, but the plan of suspension by *shortening the* whole sac contains the germ of a good idea.

I explained this method at the last annual meeting of the St. Joseph County Medical Society, and was interested to hear a description by Dr. F. C. Ferguson, of Indianapolis, of a method practiced by him, in which he draws all the coverings of the kidney, including the peritoneum, back by stitches to the lumbar muscles. To do this he opens the abdomen. In some respects this is ideal, but I should fear the loops of suture might in certain cases compress the ureter or vessels.

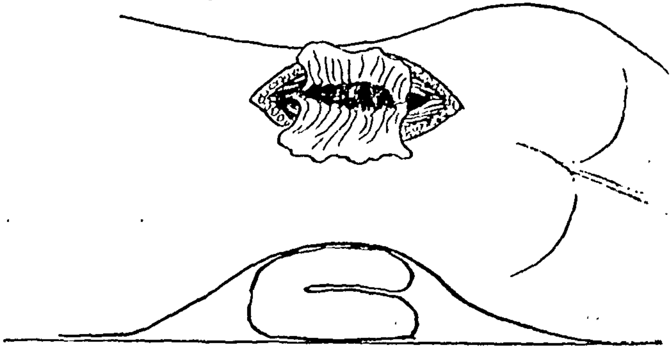


Fig. 1.—Cellular capsule split and drawn out, lifting kidney.

Dr. Harvey Reed has advocated a method also involving an anterior incision, in which the hand is introduced into the peritoneal cavity, the kidney grasped and held back in its lumbar pocket, while sutures are passed into its substance through the posterior skin and muscle, without a posterior incision. This seems to me to endanger the vessels and ureter.

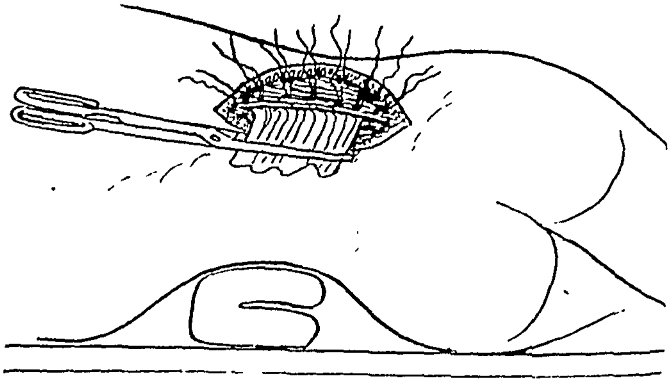

Fig. 2.—Cellular capsule clamped between muscles by mattress suture.

Dr. L. H. Dunning, of Indianapolis, was a pioneer in nephrorrhaphy, being one of the first in America to take up the work of Hahn. I am of the impression that he has made use of the fatty capsule in some of his cases. I have this statement from him:

> The article to which I referred in the discussion of your paper may be found in The Journal, Vols. IV and V, 1885. I have also found the original draft of my paper, read before the International Congress, but it does not touch any new facts concerning nephrorrhaphy.

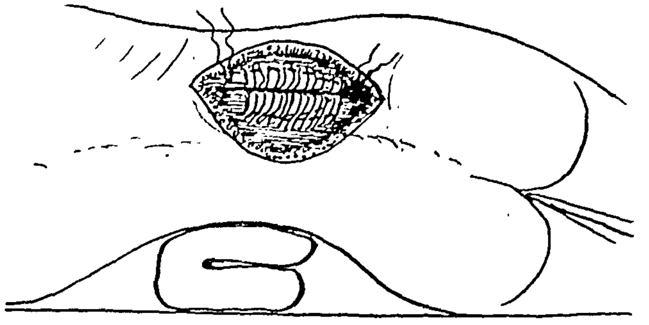

Fig. 3.—Flaps everted and sewn to muscles before closing skin.

> Upon a few occasions I used a method somewhat similar to the one you indicated, but it is not so likely to be successful

as yours, for the reason that I only pulled up the lower portion of the fatty envelope. In your operation, as I understand it, you propose to pull out between the edges of the wound a considerable portion of the cellulo-adipose envelope, and include this in the sutures that inclose the incision.

That method seems to me to be feasible, and I shall try it. I wish you success in the working out of the solution of this perplexing question. Truly yours, L. H. Dunning.

TECHNIQUE OF THE REEFING OPERATION.

1. Incision at outer borders of quadratus from twelfth rib to ilium. This is carried through the lumbar fascia and along edge of quadratus to loose fat about kidney.

2. The muscles are retracted and the fatty capsule split the whole length of the kidney. The two flaps thus formed are pulled outside, and the kidney thus held well up and back. Care should be taken that the lower pouch of this capsule is pulled high up. In cases of great prolapse, the fatty capsule will be found drawn into a long tube, like a stocking. It will surprise one who has not tried it to see how nicely it can be reefed by drawing it out of the skin opening, and how well the kidney obeys every pull we make in the upward and backward direction. It is expected that Gerota's capsule is included. Five or six inches of this fatty sac can sometimes be drawn up. The kidney will now be seen to lie snugly in the lumbar wound, and yet to rise and fall in respiration. Probably it will be an inch or more below its normal place. This is an advantage, because it removes from it the pressure of the liver, and enables us to hold the entire organ and not merely its lower pole. I have had cases of relapse by older methods in which the lower pole was still anchored by my stitches, while the upper end tilted forward and could be felt below the costal arch in front.

3. The broad segments of the fatty capsule, and its enclosing, or Gerota's, fascia already drawn outside are now held by the hands of an assistant or by long forceps, while the opening in the muscular wall is closed by a line of mattress stitches. These transfix the fatty capsule. The real support is obtained, however, not by the stitches, which would cut out, but by compression between the muscles.

4. The flaps should now be cut off an inch or two outside the muscle, everted and stitched down, after which the skin can be closed in any simple manner. In Dr. Steele's case we brought the fatty capsule out through the skin also, and cut off the surplus. These wounds seem to belong to a class in which primary healing is easily obtained.

REPORT OF OPERATIONS.

Case 1.—M. F., aged 27, multipara. First noticed dragging pain and soreness two years previous. The right kidney descended so far as to touch bladder, and was easily palpated in any position. No enteroptosis.

Operation, with oblique incision. Kidney drawn easily into wound and held by broad ligament forceps clamped on fatty capsule. The latter was drawn out and upward four or five inches outside skin. In this case I had not thought of the mattress stitches, and I used interrupted catgut of large size, closing the muscle, and compressing the fatty capsule into a roll which had a tendency to keep the muscles apart. The skin was closed over with buried catgut and a collodion seal on wound.

Primary union occurred, and thirteen months after operation there was no return.

Case 2.—Miss G., aged 24. Some history of dyspepsia, and dilated stomach. Had for seven or eight years pain and dragging in right side. The movable kidney was discovered by her physician, who advised a supporter. This gave only partial relief.

Operation, with vertical incision from ribs to pelvis. Quadratus and psoas formed inner boundary of muscular cut. Capsule drawn freely up, held with two broad ligament forceps, and a line of mattress stitches made to grip it while closing the muscle. Skin closed over the whole, and a small drain inserted. After the skin wound was closed, a flat tumor formed by the excess of fatty capsule could be felt and seen outside the muscle.

This patient had no recurrence after six months.

Case 3.—Miss S., aged 32. For nine years had had pain in walking, some gastric disturbance, neurasthenic symptoms, and a palpable tumor in right side, which descended as far as the anterior superior spine of the ilium. When held in position by the hand, patient felt much relief, and also in lying down. No bandage had been found which did not seem to increase the trouble by getting above the kidney and pushing it down.

Operation, by vertical incision from ribs to pelvis. Quadratus and psoas as usual formed inner boundary of the muscular cut. Adipose capsule was drawn out, after dividing it lengthwise, and held by two long clamps. The kidney came well into the wound. Eight mattress stitches of chromicized formalin gut were used to close the muscles, and this seemed to hold the capsule very smoothly. The fatty flaps were then turned outward, and sewn to the muscles in opposite directions, after which the skin was closed with buried sutures, and a small bundle of silkworm gut left in the lower angle.

Primary union occurred here, and no recurrence had appeared after five months.

Case 4.—Miss H., a patient of Dr. D. A. K. Steele, aged 25. Has had a right wandering kidney for several years, causing local pain, malaise and nervous symptoms.

Operation, at Chicago Hospital, by Dr. Steele, assisted by myself. The oblique incision was used, and the kidney easily found. The fatty envelope was divided longitudinally. The two flaps thus formed seemed to have considerable strength, and all present noticed that the organ could be drawn up and held quite snugly against the posterior opening, while at the same time its respiratory movement did not cease. Catgut sutures were used, and the capsule drawn outside both muscles and skin.

No recurrence has taken place up to the present time.

Case 5.—Mrs. M. V., multipara, aged 42. After a miscarriage two years ago had pain or sense of weight in right side. Dr. Eisendrath diagnosed wandering kidney.

Operation, at Post-Graduate School, by Dr. Eisendrath and myself. Vertical incision as before. Fatty capsule drawn out and held by two forceps, while sutures were placed mattress form, fixing it between muscles. The fatty capsule seemed a little more frail and tore easier than in my other cases. The skin was closed and a small drain placed in lower angle.

A relapse occurred in this case very early, whether from some imperfect carrying-out of the technique or some inherent fault of the method, I should be glad to know. At a recent examination I found both kidneys markedly prolapsed, but the left more than the right.

Case 6.—Miss A. R., aged 15. Had been under [illegible] son's care for gastric dyspepsia and [illegible] and on account of persistent pain in right side. [illegible] showed wandering kidney, with an [illegible] of pelvis.

Operation, with vertical incision [illegible] capsule. The latter, in two flaps, was drawn [illegible] the mattress sutures of catgut [illegible] capsule were then everted and [illegible] catgut. After closing the [illegible] form a slight tumor.

No relapse has appeared in [illegible] operation.

Case 7.—Miss G., aged [illegible] pepsia for several years. [illegible] sides. The duration [illegible] tacks of severe left [illegible] calculi size of peas

Dr. Fütterer advised exploration of left kidney, and nephropexy of both. In a previous double nephrorrhaphy on one of Dr. Fütterer's patients I had used the old method, but I had now acquired enough confidence in the new operation to use it in every case.

Operation, on right kidney with vertical incision. On left side the oblique cut, one inch below the twelfth rib, was used, so as to be prepared for removing stones, and possibly following ureter. The kidney was explored digitally, and by needling, and as no signs of pyelitis or calculus were discovered, the reefing operation was done on both sides. The fatty cellular capsule was reflected upon the muscular flaps, while the latter were closed by mattress sutures of catgut. The reflected capsule was then sutured down on each side. The wounds were drained with iodoform gauze, extending to the lower pole of each kidney. Primary union was obtained, and the patient sat up on the eleventh day.

This case is too recent to have much value in the statistics. So far, the result has been perfect.

CONCLUSIONS.

1. The adipo-cellular capsule and Gerota's capsule are strong enough to hold up a wandering kidney.
2. Stitches can not hold this tissue, but pressure between flaps may do so.
3. Nephropexy will often fail in wandering kidney brought about by gastroptosis and enteroptosis.
4. The new method—reefing operation—has been tested from one to thirteen months, and has shown fair results.
5. The interposed fascia has not caused failure of union in any case.

ACUTE GRAVES' DISEASE.*

JAMES R. ARNEILL, M.D.

Instructor in Clinical Medicine, University of Michigan.

ANN ARBOR, MICH.

The diseases described in text-books under the heading, "Diseases of the ductless glands," are usually chronic in their course. There are interesting exceptions to this rule. Fussell and Taylor have collected from literature 56 cases of acute leukemia in which death occurred in from two to three months. Graves' disease is still more strikingly chronic in its course. The number of fatal cases of acute Graves' disease reported by American authors is remarkably small. The only fatal cases which I have been able to find are those of J. H. Lloyd[1] and F. P. Henry.[2] A few cases have been reported in which the symptoms of Graves' disease came on suddenly, lasted for a few days, and disappeared with recovery. In French, and especially in German, literature, the reported cases are more numerous, but still rare. Cases of this interesting form of the disease have been reported by the following authors, besides those referred to above: Trousseau,[3] Peter,[4] Roth,[5] Foerster,[6] Gräfe,[7] Freudenberger,[8] Mackenzie,[9] Solbrig,[10] Eger,[11] Reymond,[12] Mueller,[13] Hirschlaff,[14] Sutcliff,[15] Moore,[16] Kinnicutt,[17] and Patterson.[18] The case which I wish to add to this list of acute Graves' disease died while under my care at the University Hospital.

Mrs. P., aged 33, married, born in Germany, but a resident of Michigan for many years, occupation, housewife. Her father died at 75; had articular rheumatism for thirty years previous to his death. Cause of mother's death not known. One paternal uncle had rheumatism. The patient was well as a child, and had none of the ordinary diseases of childhood. Menstruation began at 18, was regular, normal in amount, and without pain until three years ago, when her periods, which lasted three days, were followed by severe pains in the front of the thighs, and a white discharge from the uterus, which lasted three days. Menstruation ceased entirely one year ago, with disappearance of the pains in the thighs. Patient was married at 22, and one year afterward was confined at 7 months, child being still-born. Overwork was thought to be the cause of this premature labor. A second child was born two years later and lived 12 months. A third child is 8 years old and in good health. Articular rheumatism began in one finger sixteen months ago, and gradually involved nearly all the joints of the extremities. The thyroid gland began to enlarge seven months ago, nervous symptoms soon developing. The patient's husband states that severe nervous symptoms and palpitation of the heart developed less than four months previous to the patient's admission to the hospital, immediately following a severe shock. The patient's only son was sick at this time with appendicitis. An operation was planned and the mother was almost prostrated with grief and anxiety. The symptoms appeared immediately after this shock. During the past two months the patient has been too weak to work. The bowels have moved four or five times daily and urine was voided with difficulty. There is constant thirst. The patient has grown rapidly weaker, emaciated, more nervous, and the diarrhea has continued.

Status Præsens.—Patient has the appearance of a very sick person; body is emaciated, though face is fairly full. She is extremely nervous and so restless that examination is made with difficulty. Mind is clear. Height a trifle below average; present weight 74 pounds, four months ago, 140 pounds. Frame slender, musculature very small and soft, panniculus very thin; skin of a light brown color, especially on face, very moist, patient sweating profusely; mucous membranes a trifle pale, tongue thick, with a fairly thick grayish coat on dorsum, teeth poor, no edema at ankles, joints not deformed. The thyroid gland is enlarged in both lobes and isthmus. The tumor extends from the clavicle to the angles of the jaw. The right lobe is the larger. There is marked pulsation in all of the veins and arteries of the gland, and over the gland. On palpation a fine thrill is felt. A loud "bruit de diable" is heard over the gland. Circumference of neck is 37.5 cm. There is no exophthalmos. Von Græfe's sign is absent. Mœbius' sign is positive, as the eye can not converge for any length of time. On extending the hands a fine tremor is noticed. Thorax is rather small, of fair length, is deep and narrow; epigastric angle of fair size. The sternum projects and the angle of Louis is prominent. Expansion is small. Percussion of lungs is negative. On auscultation over right apex expiration is louder than inspiration. Over left apex inspiration is louder than expiration. Over remainder of front there is a weak, somewhat sharpened, vesicular murmur.

The apex-beat of the heart is in the fifth intercostal space, nipple line, and is heaving. On percussion, dulness begins on fourth rib and extends to left, to nipple line, is not enlarged to right. On the first sound at the apex there is heard a harsh, fairly loud murmur, which is well transmitted to the left axilla and is heard over the entire front of the chest. The second pulmonary sound is louder than second aortic, but is not particularly accentuated. Liver and spleen are not enlarged.

The lower border of the stomach is just above the umbilicus. Succussion sounds are present.

The patient was admitted to hospital April 11, 1899, with a temperature of 100, pulse 140, and respiration 30. She was very much exhausted and nervous, partially as the result of a long trip. Following our usual custom in the treatment of Graves' disease, the patient was put to bed and placed upon a light diet, because of an irritable condition of the stomach. An ice bag was applied over the heart, and strychnia, gr. 1/30 t. i. d. were given for three days, then thyroid extract was given in a tentative way, gr. v, t. i. d., and dilute hydrochloric acid after meals. These were continued for seven days, when all medicines were stopped, as the patient was vomiting and had a severe diarrhea. At this time she was taking broths, egg nog, milk and malted milk, but on attempting to swallow anything, vomited and retched fearfully, producing great exhaustion. On the twelfth day she took 23 oz. of malted milk, did not vomit, but had a number of watery stools; temperature was about 100 and pulse 122. On the thirteenth day she refused most of her nourishment, vomited once, and had a large number of soft stools. On the fourteenth day strychnia was resumed and patient retained most of her food, which consisted of broth and malted milk. On the seventeenth day, on account of diarrhea, bismuth, paregoric and chalk mixture were given, and peptonized milk was given as food. On the eighteenth day she refused most of her food and vomited frequently. Rectal feeding was now begun. Nineteenth day was a very hard one; most of the nutrient enemata were expelled, stools very numerous and watery, and she vomited frequently. Temperature varied from 99 to 101 and pulse ranged from 134 to 150. Patient was very weak and restless. On the twentieth day the patient was very restless; nutrient enemata were given, but most of them were expelled. At times she was so restless that the temperature could not be taken; morphia hypodermically and bromids were given per rectum; temperature rose to 104.5, pulse 160. Patient became wildly delirious—could not be controlled—and raved continuously. On the twenty-first day she grew more wildly delirious and could scarcely be kept in bed; temperature rose to 106.2, pulse to 200; at 10 a.m. temperature reached 107 and it was impossible to take the pulse. Patient died at 12 m.

---

*Read before the Detroit Medical and Library Association, May 14, 1900.

Unfortunately, I was unable to secure an autopsy. The most salient points in the case are the cessation of menstruation one year before death, the appearance of the goiter seven months before death, the advent three months later of palpitation of the heart, tachycardia and nervousness, immediately after a profound emotional shock, the presence of diarrhea and vomiting, the great loss of weight—nearly seventy pounds in four months—the high pulse-rate and the high temperature toward the close of the illness, the presence of delirium and the complete absence of any evidences of exophthalmos.

From an etiologic standpoint the question of shock is an important one. A large number of cases have been reported in which the signs of exophthalmic goiter developed immediately after some profound emotional disturbance. Case 1, of Mueller's[14] series, was abruptly told of the death of Kaiser Wilhelm, and thought reference was made to her sister, who at the time was very sick with typhoid fever. She immediately became so weak that she took to bed, palpitation of the heart came on, loss of appetite and vomiting, exophthalmos and struma.

Trousseau[3] relates a case in which three cardinal symptoms of the disease appeared in a single night in a woman who had been greatly affected by the loss of her father. Kinnicutt, in the "American System of Practical Medicine," speaks of the following case in his practice: A woman, at sight of her husband covered with blood, was seized suddenly with violent palpitation and tremor, followed speedily by enlargement of the thyroid and protrusion of the eyes. Reymond[13] reports a case in which acute symptoms suddenly appeared following anxiety in a woman of 45, death occurring on the fourteenth day.

Sansom—"Allbutt's System," Vol. ii—reports a case developing suddenly after fright, but ending in recovery. Moore—cited by Ord and McKenzie in Vol. iv of "Allbutt's System"—reports a case occurring in a young girl after reading of her brother's death, in which the symptoms lasted only two days.

Some of the signs and symptoms of this disease have also developed following operations, severe attacks of pain, the administration of an overdose of thryoid extract and the section of the cervical sympathetic. In Mueller's series, Case 2, five years before the beginning of the disease, had a sudden blow upon the nape of the neck. In the third case, gall-stone colic preceded the attack many years. In Case 4 there was a long attack of fever of an unknown kind, following which the patient never entirely recovered.

Patterson[10] reports a case in a girl of 15; tonsillotomy was performed. A good deal of agitation and tremor of the hands were noted at the time of the operation. In the course of three weeks enlargement of the thyroid, tachycardia and exophthalmos developed. The tremor also extended to the legs.

If the histories of many of the reported cases of this disease had been worked out carefully, it is my belief that in the majority of them signs, though indistinct, of a pre-existing incomplete Graves' disease could have been obtained. The fright, grief or worry is simply an accidental factor in the disease, which has accentuated the signs already present and hastened the development of others. The entire human family would be suffering from Graves' disease if fright, shock and worry were sufficient causes. There is at this time either an unstable condition of the emotional nervous system, or the disease is present in its incipient stage. In my own case menstruation had ceased five months before the goiter was noticed, and eight months before the severe shock. Articular rheumatism, involving most of the joints, preceded the development of nervousness and tachycardia by a year.

In Reymond's case there was continuous tremor for *more than a year preceding the acute attack.* In Patterson's, the patient had been troubled with tremor of the hands for eighteen months, which had occasionally made writing difficult. Kinnicutt reports a similar case, in which, before there was any evidence of palpitation, a trembling of the hands had interfered seriously with his occupation of bookkeeping. Enlargement of the thyroid occurred six weeks later. In these cases the tremor was an evidence of the existing Graves' disease. Hirschlaff's case had palpitation of the heart and dyspnea at time of menstruation for nine years previous to the acute development of the disease. In 1895, after a fright, convulsions and unconsciousness supervened; similar attacks occurred every month, preceded by paresthesia of hands and feet. Excitement and anger brought on the attacks.

In the majority of acute fatal cases of this disease there is a history of uncontrollable vomiting and diarrhea, which soon exhausts the patient. In Sutcliff's case this feature was very prominent. Vomiting persisted in spite of all treatment till death. For three weeks no food was taken, even the sight of food bringing on distressing vomiting.

J. H. Lloyd's patient was thought to be suffering with cholera morbus. When examined in a good light the cardinal signs of Graves' disease were found. Vomiting continued, prostration became marked, pulse rose to 170, and was tumultuous; patient died at end of third day of illness. Post-mortem was performed by Dr. Dock, showing heart, lungs, kidneys and suprarenal capsules practically negative.

Hirschlaff's case, toward the end, had diarrhea. In Mueller's four cases symptoms on the part of the abdomen ushered in the scene in three cases; there was gastralgia, vomiting and diarrhea, the diarrhea being especially persistent in the fi[illegible] I[illegible]ree of his cases; the voice acquired a [illegible]ng ton[illegible]less and soft. Several sh[illegible] in slurring of the speech.

Psychical condition.—All four of Mueller's cases showed great restlessness, irritability and excitability. The great motor restlessness continued until death. The first three cases had delirium at the periods of exacerbation. Case 4 had feelings of anxiety, associated with frightful dreams and hallucinations. My case showed wild delirium toward the close. Henry's case was markedly delirious. Hirschlaff's case showed great restlessness, amounting almost to choreic movements. A number of hysteric attacks occurred following trifling annoyances. Very rapid tremor was present in all four of Mueller's cases. It was also marked in Hirschlaff's case and my own. Patterson's, Reymond's and Kinnicutt's cases all showed fine tremors. Charcot first called attention to the tremor as a symptom in Graves' disease. Marie thinks it presents characteristics which distinguish it from all other forms of tremor. The to-and-fro movements of Graves' disease occur at a rate of 8 to $9\frac{1}{2}$ per second, whereas the tremors of paralysis agitans, general paresis, alcoholism and general senility are much slower, about 4 to 5 per second, and more regular. The importance of the presence of tremor should be emphasized because of the assistance it gives us in diagnosing incomplete and incipient forms of Graves' disease.

The number of post-mortems on acute cases of Graves' disease is small. Mueller makes the following reports in the cases examined by him:

Case 1 died three and a half months after beginning of the disease. Numerous small fresh hemorrhages were found in the medulla oblongata, especially in the neighborhood of the vagus nucleus, and in the upper olive body; otherwise the cerebral peduncle, pons, oblongata and spinal cord were normal. The vagus trunk showed considerable degeneration on both sides, in slight degree also the recurrent vagus and the heart nerves. The sympathetic appeared entirely normal. Near the enlarged hyperplastic thyroid were a number of lymphatic glands the size of cherry-stones, showing fresh and old hemorrhages throughout their substance.

Case 2 died in a little over two months from the beginning of disease. Struma, slight heart hypertrophy and numerous swollen lymph-glands in the neck were present. The spinal cord, medulla, pons and cerebral peduncles were normal. On the floor of the fourth ventricle were rather numerous, fresh hemorrhages, arranged especially in and about the vagus nucleus. The sympathetic was *normal.*

Case 3 died in less than six weeks from beginning of disease, and showed nothing abnormal either in brain or medulla, except a moderate degree of edema. The sympathetic was normal. Besides the old cholelithiasis there was struma and brown hypertrophy of the heart muscle.

Case 4 did not come to the post-mortem table.

Case 5 was a subacute one, dying after ten months of illness. Post-mortem showed the sixth and eighth dorsal vertebræ carious. There were several small fresh hemorrhages in the fourth ventricle; no other changes in the brain. Vagus, recurrens, cardiac nerves and cervical sympathetic without demonstrable changes. The dorsal sympathetic in the neighborhood of caries was interrupted. The splanchnic was normal; thyroid hyperplasia; no hemorrhages; numerous swollen cervical lymph-glands were hyperplastic and studded with fresh and old hemorrhages. There was brown atrophy of the heart. Seeligmueller (Lehrbuch der Nervenkrankheiten) reports a similar case of Basedow's with spondylitis, which recovered. Peter reports a case which died after an illness of eight days, in which both lower cervical ganglia were enlarged, the ganglion cells small and in part granular, and the nerve elements diminished. The upper middle cervical ganglia were normal.

In Hirschlaff's case post-mortem showed adenoma of the thyroid, hyperplasia of the thymus, tonsils, spleen and of the adenoid tissue in the stomach and intestines, hypertrophy and dilatation of the heart.

The only pathologic lesion which is found constantly present in these cases of acute Graves' disease is the diseased thyroid gland, which is usually hyperplastic. Supporters of the theory that disease of the sympathetic nervous system is the cause of Graves' disease point to the fact that Beveridge, Smith, Knight, Virchow, Biermer, Moore, Hopfengærtner and Johnson have all reported cases of Graves' disease in which changes were found in the sympathetic.

Analogous changes in the sympathetic, however, have been found in other diseases, such as traumatic neuroses, Bright's disease, tabes and diabetes. On the other hand, the supporters of this theory must remember that in numerous cases of Graves' disease the sympathetic has been found to be normal. Pathologic changes in the brain and cord are not sufficiently constant to give them any importance from an etiologic standpoint.

The striking difference between acute and chronic cases lies not in the pathologic findings, but in the greater intensity of the symptoms, especially those on the part of the gastro-intestinal tract, evidencing a more profound intoxication with perverted or excessive normal thyroid secretion.

Treatment is of no avail. Digitalis, strychnia, bromids, morphia and thyroid extract have all been used, and with indifferent results.

The use of thyroid extract in Graves' disease, acute and chronic, is condemned by many as irrational. If one accepts the theory that Graves' disease is the result of an excessive secretion of the thyroid gland, it certainly would be illogical to prescribe thyroid extract. It would be just as sensible to give hydrochloric acid in Reichman's disease and expect an improvement in the symptoms. *However, upon the ground that this disease* is the result of an absorption of an excessive amount of perverted thyroid secretion it is good treatment to give these patients thyroid extract. By supplying artificially a normal secretion, it is possible for a diseased organ to recuperate and regain its normal function. In diseases of the stomach with subacidity we prescribe hydrochloric acid, and in many cases, the stomach regains its power to secrete a normal gastric juice. In the treatment of the disease we must guard against drawing too favorable conclusions regarding the efficacy of therapeutics. The disease is prone to improve without or in spite of treatment. On the other hand, exacerbations may occur during treatment, and one is led to think that the medication is responsible for the relapse, when it is without blame. It can not be foretold whether thyroid extract will do a patient good or harm, but many patients with the chronic type of the disease have improved under its use, and it seems a justifiable clinical experiment to try this drug in the treatment of Graves' disease.

SATURDAY, OCTOBER 6, 1900.

MEDICAL ORGANIZATION AND THE REORGANIZED NEW YORK STATE MEDICAL ASSOCIATION.

The pernicious conditions existing in the medical profession, regarding its material interests, is a subject which calls for the consideration and earnest thought on the part of all the members of that profession who are interested in its welfare. These conditions are many and varied, and too well known to need repeating here. In every instance they are the result of a lack of organized effort, on the part of the profession itself, to remove them.

Organization in the medical profession of the United States is at present best defined as "chaotic." While there are nearly fifty states and territories, and as many state and territorial societies, there are also nearly as many plans on which these are organized. A few are based on the county society, membership in this carrying membership in the state body; a few others, recognizing the value of the county organizations, encourage them in a half-hearted manner; a majority of the state societies absolutely ignore the local society.

The basis for the complete organization of the profession must be the county or local society; this must be regarded as an axiom. Another assertion must be accepted as a truth before a complete and permanent organization may be looked for: The objects of the organization must include the material, as well as the scientific, welfare of the individual members. The average physician is only human, and he asks for a material return for the money and energy he has invested. This must come directly to him as an individual, or indirectly as a member of a profession which he sees materially benefited as a result of his investment. While the scientific and educational advantages of the ordinary medical society are alone sufficient to satisfy the few, the many are not so satisfied; they want something more. The state medical society which attempts to completely organize the physicians in its territory without recognizing these fundamental principles will fail in the future as it has failed in the past.

Holding these views, we can but endorse the plan on which the New York State Medical Association is being reorganized, for it is evident that the committee on reorganization has recognized the necessity of this broader plan in formulating its charter and organic law. According to these, the reorganized New York State Medical Association is to be the central body in which the sixty-one county associations, when organized, will unite, and through which the combined county associations will work. Its fundamental principle is fair and equal representation, leaving no chance for the formation of cliques, or a possibility of its management getting into the hands of a few. The Association has just issued a pamphlet which contains the new charter and proposed laws, together with the proposed by-laws for district and county associations, from which we obtain the following information:

The subordinate bodies of the State Association are the "district branches" and the county associations. Of the former there are five—First or Northern; Second or Eastern; Third or Central; Fourth or Western, and Fifth or Southern district branches, each including from ten to fourteen counties.

The membership is composed of resident, non-resident, corresponding and honorary members, all but the first being non-residents of the State. The active voting members are called "Fellows" and are delegates elected by the county associations annually in the proportion of one for each ten active resident members. These, as do all the officers, serve one year. They meet with the Council annually on the day preceding the regular annual meeting of the State Association, conduct the general business of the Association and elect officers.

The "Council" consists of the fifteen officers of the Association, i. e., president, vice-president, five ex-officio vice-presidents—these being the presidents of the branches—secretary, treasurer and the chairmen of the six standing committees. It is the active working body, the executive board of the Association, and during the intervals of the meetings of the larger body, manages its interests.

Members are not elected to the State Association directly, but obtain this membership through that of a district branch, or county association. To become a member of a district branch the applicant must be a resident of the district included in that branch, and of a county in which there is no affiliated association. Residents of those counties in which there is a county association must obtain their membership in both the district branch and in the state organization through membership in their own county association. When the members of any district branch, residing in one county, are ten in number they must organize a county association, and thereafter control memberships from that county. This, in brief, is the plan, which means that to become a member of the State Association the applicant must be a member in good standing of his local association, if there is one, and, if not, of the district branch, membership in the county carrying with it membership in the branch and state associations without further fee. It means the building up of the local associations. Each county and branch association elects its own officers, controls its o [illegible] an [illegible] s its ow [illegible] laws, but these must be i [illegible] v [illegible] organ [illegible] laws of the State Asso [illegible] th [illegible] there are many counties in which there is no local association, the district associations are necessary, but whether this will be true when all the counties are organized time will tell. It is presumed that each of the district associations will now work energetically to organize an association in each county, so that, before long, it is hoped we may look for an association in every county in the State.

Two important provisions are incorporated in the charter and by-laws which have reference to what we have designated above as the "material interest" of the individual member. The first of these provides for the establishment of a death-benefit fund. Section 4 of charter is as follows:

> The New York State Medical Association may, in its discretion, establish a death-benefit fund, and may include in its by-laws an article governing the establishment and distribution of the said death-benefit fund.

Whether a life-insurance department is advisable or not we are not prepared to say. We understand that a suggestion has been made that, instead of this, provision be made for creating a fund to be used for the superannuated among the members, in other words, provision for old age rather than for the dependents of a deceased member. In any event the creation of some such fund would have a good effect in two ways: the direct good for which the fund is created, and the indirect in keeping those once affiliated in active membership. One having an interest in such a fund would naturally be more liable to retain his membership than if there were no such interest to hold him.

Another excellent provision is that covered by sections 5 and 6 of Article II of the by-laws.

> It shall be the duty of the Council to employ an attorney and counselor-at-law, resident in the city of New York, who shall appear in all legal matters for and on behalf of the New York State Medical Association. It shall be the duty of the Council to receive and consider all applications of members for assistance in defense of suits for alleged malpractice or other matters affecting their professional status, and all complaints of violations of the laws of medical practice and of public health; and the Council shall without delay, and with the advice of its attorney, examine the case and determine the expediency of defending such action or prosecuting the alleged violators. If the Council's decision be in the affirmative, then the New York State Medical Association shall furnish the funds and legal services necessary for the conduct of such defense or prosecution.

These provisions are of the greatest importance and will result in more material benefit to the profession than any other that could have been incorporated in the organic law. The great trouble in every state is that the medical laws have not been enforced; and those who have had experience in trying to enforce them know that this will never be done by the politically appointed or elected prosecutors. It must be done, if at all, by physicians; and as there is not a state in which they are thoroughly organized, there is not a state in which the medical laws are enforced. Our friends in Kentucky have come nearer keeping quacks out of their state than has been done in any other, and this is because a few have been well supported in every way by the many. Hence, we believe the provision made for this work in New York is destined to result in good in many ways.

The provision made for the assistance of members in the defense of suits for alleged malpractice, when justly brought, is such an excellent one that it needs only to be mentioned to be commended. The resisting of suits for alleged malpractice is as much the duty of the profession as a whole as it is that of the individual directly affected; for the success of one of these suits, either by compromise or otherwise, is liable to bring on a dozen others.

The reorganization of all state societies on a uniform basis has been proposed, but what the ideal plan would be which each state would be invited to adopt is a question which requires earnest and careful consideration. The above outlined plan, which the New York State Medical Association at its meeting this month will consider—for it has not yet been adopted by that body as a whole—has many excellent features; whether it can be made more ideal is for the future to decide.

HOSPITAL ORGANIZATION.

The method of organization of the medical staffs of our hospitals is a matter of great importance. Naturally the same plan, even though quite ideal, is not applicable to all hospitals, because their scope and nature differ greatly. In the case of those of large or medium size, whether supported by some branch of the government or by endowment, the general conditions are usually quite similar, and it would seem natural that the medical staffs were appointed and organized according to some well-considered plan which had gradually met with more or less general approval. At present, this is far from being the case. In most of our city and country hospitals the positions on the medical staffs are prostituted in the interests of practical politics. There is no reasonable certainty in the tenure of office; there is no esprit de corps in the staffs so constituted, and no successful attempt can be made to organize them into harmoniously working bodies, because of the total absence of high motive and of proper training in most of the appointees. Such hospitals are usually scientifically sterile. The limitations of the authority of the attending physicians and surgeons and of the non-medical officials are illy defined and not infrequently lead to occurrences of whose disgraceful character the least said the better. Naturally, there is but little discipline among the internes in such hospitals. Fortunately, there are institutions in which better systems prevail, and it seems that the conditions in general are slowly improving in most of the large cities.

In the hospitals maintained by endowment or by religious bodies the conditious are, on the whole, somewhat better, certainly more refined, yet in these is seen a rather low standard of organization that leaves much to be desired. Speaking generally, the attending clinicians in both these groups of hospitals give their services free to the non-paying patients. In some hospitals this means that an attending clinician may take free charge of 50 to 75 patients for shorter or longer periods of time each year; in others, year after year. In hospitals admitting private and pay patients the opportunities for "making money" are often most inviting, especially in surgical work. Hence the fact that in some institutions the number of surgical patients greatly exceeds that of medical. The chief shortcoming of such hospitals is the lack—often absolute—of systematic scientific clinical work of general value. The spirit of commercialism prevails.

In order to improve on the present conditions certain broad general policies should be introduced into hospital management. In the first place, the appointment of hospital staffs should be taken out of politics. This needs no further explanation. The hospitals, especially the larger, should be subdivided into distinct, definite, and, within certain limits, autonomous departments or services, each with its own chief or head, assistant, or assistants, residents, and internes. In a hospital large enough to maintain two surgical departments, each should be independent of the other. Common operating-rooms, common assistants, etc., destroy individuality and hinder the development of the department as a whole. The service should be continuous and practically permanent. The fragmentary service of three months a year, or the like, is incompatible with good work. Apply the principle to other lines of activity and its absurdity is at once apparent. The chief of service should be the best available man for the position, the attainment of which under the conditions briefly outlined here would constitute in the end one of the highest honors a medical man in this country could hope to reach. The proper mode of selection could be worked out easily. The time of service of the assistants, residents, and internes should be arranged with two points in view: the greatest good of the department, and the thorough training of young men. Lastly, the principle that a servant is worthy his hire, is as applicable to hospital work of a responsible character as to any other employment. The custom that physicians should give their time and their services to the extent now prevalent here without the principle of compensation being recognized directly is not only without parallel, but directly detrimental to clinical work of a high degree. Here, we meet with the awkward complication of two spheres of work, one public or semi-public, the other distinctly private. The adjustment will work itself out with time if the principle at stake, and we believe it is a correct one, is recognized, as is the case already in a few institutions in this country and quite universally elsewhere. The affiliation of many hospitals with medical schools and with universities greatly simplifies the problem. Finally, in hospitals so organized may we hope that scientific clinical and pathological study and investigation will be carried on to an extent that speedily will increase manifold the value of the services of the hospital and that in a much larger and more broadly humanitarian sense than under the present haphazard methods of regime.

SOME SOURCES OF ERROR IN SKIAGRAPHS.

Every method of physical exploration can yield information only with regard to physical conditions, but for the establishment of the anatomic and physiologic significance of which other data will be required. It should hardly be necessary to add that the observations must themselves be in the first place above suspicion. Here, as in the application of all methods of precision, are demanded the two essentials of correct perception and equally logical interpretation, and both of these bespeak a certain foreknowledge. While the large possibilities for diagnostic usefulness of the X-rays were early appreciated, it soon became recognized that the results obtained were susceptible of varied interpretations, in accordance with the skill and the experience of the observer and the opportunities for the development of what, for want of a more convenient term, may be designated "artefacts."

Some of these sources of error are pointed out in a communication presented to the Society of Medical Jurisprudence, of New York, by Dr. Carl Beck,[1] who speaks from an extensive experience. To reduce the likelihood of error to a minimum, it should always be borne in mind that the X-rays produce only shadow-pictures, for the correct interpretation of which a thorough knowledge of the anatomic relations of the parts is absolutely essential. The density of the shadows produced will necessarily vary with the position in which the picture is taken, and, for purposes of control, the observation should be made in at least two directions. For purposes of precise localization it may be necessary to make several observations and to employ special devices. One must always first assure himself that the shadows found are not due to the presence of normal structures, even though these be at times unusual, before deciding them of abnormal origin. It is, therefore, often useful to compare opposite sides of the body under like conditions. As has been indicated, the possibility of anomalous or exceptional conditions, in themselves not abnormal, should always be borne in mind. Then, the incompleteness of ossification in the young, and the bone-changes attending rachitis, for instance, may give rise to appearances in skiagraphs simulating the results of traumatic lesions. It is further appropriately pointed out that the apparent deformity disclosed by the skiagraph is not a trustworthy index of the degree of disability. The point ever to be remembered in the employment of any and all methods of physical diagnosis is that [illegible] results yielded are in themselves [illegible] lu- [illegible] their significance will depend on the interpretation given them, and this will be governed by a full knowledge of all the possibilities in the case.

---

[1] Medical Record, August 25, p.

AMBIDEXTERITY.

Dr. E. Noble Smith[1] makes a plea for the education of children in the use of their left hands interchangeably with their right, instead of as at present discouraging it. The inconvenience of having to use the left hand for all manipulations when the right happens to be temporarily disabled has been experienced by many of us and we can therefore the more readily appreciate his argument. It certainly would be an advantage if one could be equally dexterous with both hands, and the fact that some favored individuals are naturally thus endowed makes it seem possible that by education all could be made ambidextrous. We are usually inclined to believe with Sam Patch "that one man can do a thing as well as another;" why, therefore, should we all not use our left and right hands alike if we so wish? The almost universal prevalence of right-handedness, however, must have some physiologic basis, and this being the case it may not be so easy to correct the tendency. It is probable that the selection of the right or left hand for special training is a matter of custom and choice; whole nations are, like the Benjaminites of Scripture, said to be predominantly left-handed, but it is none the less the rule that one or the other hand is more dextrous and more used. Man is not a symmetrical being, his viscera are distributed according to his needs, and this fact has been used in theorizing as to the cause of the phenomenon, as noted by Smith. He does not, however, refer to the elaborate speculations of De Fleury and others on the effects of the unequal blood-supply of the hemispheres of the brain, which would appear as likely as anything else to have an influence.

A still more striking indication, as it might seem to some, pointing to the physiologic reasonableness of one-handedness, is the fact that the speech centers are almost invariably located on one side of the brain. There is, as regards the faculties of expression, a close relation between the hand and the organs of speech, and it is in this relation particularly that the inequality of the two sides is most manifested. We can learn with comparative ease to use the left hand for many purposes nearly or quite as well as the right, but it is a much more difficult task to accustom it to write, that is, at least for most of us. The fact also that children who happen to be originally left-handed are easily taught to use their right hands, but then lose their facility with the left—become right-handed instead of ambidextrous—would seem to point to an inability of the average brain to utilize both hemispheres simultaneously to the same extent. Adults who educate themselves out of left-handedness into right-handedness generally do this imperfectly, their right hands can only be approximately perfect in certain specialized movements; they rarely, if ever, become perfectly ambidextrous. Even ambidextrous—so-called—individuals have a preference, which must be based on some greater ease of use, for one hand or the other. All these facts, together with the additional one that in movements of the lower animals there is a certain degree of unilateral predominance, indicate that one-sided function is natural and due possibly to an inherent incapacity of the average brain to work both sides alike. There are still other facts in connection with aphasia that are suggestive in this connection, but they need not be considered here.

The question remains, if unilateral function is the normal condition and bilateral equivalence the rare exception, might not the attempt to educate the average individual into ambidexterity result in a lower grade of functional performance? In other words, is it in the best interests of the child to attempt to make it ambidextrous? According to Noble Smith, this is already being attempted by the school authorities of Philadelphia and it will be of interest to note their success.

DIED AT HIS POST.

The death of Dr. Jesse W. Lazear, noted elsewhere, is another sacrifice on the altar of professional duty. Dr. Lazear's work in the investigation of yellow fever was such as demanded a man of his ability and qualifications, and he fearlessly devoted himself to it, rendering services that are spoken of in the most appreciative way by his superior, the head of the army medical department. If any man ever gives his life for others it is the physician who dies the victim of disease contracted at the post of duty. It is to the honor of our profession that such cases are not rare.

THE TEXAS MEDICAL LAW.

The medical examining board for the Texas judicial district including Houston, recently resigned in a body for good and sufficient reasons. While the law provides for such a board to examine diplomas and undiplomated candidates for the practice of medicine, recent judicial decisions have declared that the diplomas of any one legally incorporated institution for medical education are as valid as those of any other. Thus, the most fraudulent concern is placed on the same level as the best, and, as a defense of the public against quacks, the law is nullified. No self-respecting physician would care to hold an office the function of which is to license the diploma-holders from the Armstrong succession of chartered frauds. Hence, the board very properly resigned. The members of the other Texas boards would do well, if indeed they have not already done so, to follow their example. The Texas State Medical Association has elaborated a bill for a medical practice act corresponding in the main with those of other states that require an examination as a preliminary to the issuance of a license. It is to be hoped that it may soon become a law, and it will if the members of the medical profession in Texas do their duty and exercise the influence they possess.

[1] British Medical Journal, September 1.

THE RAW MEAT FAD.

Twenty-three men and women of Chicago, where Dowie throve and Schweinfurth sprung, have organized themselves into a "Raw Food Society" and propose to start a propaganda. The basal idea of this organization is best explained by the resolutions adopted, in which they state that it is their firm conviction that life will be lengthened, pestilence and contagious disease wiped out of existence, and men will become *giants physically, intellectually and morally* by abstinence from cooked food. It was never intended, said their president, "that man should eat food that has been cooked, that he should take into his system dead cells to replace the worn-out cells cast off from the body." Just how these reformers are to get along with the ordinary conventionalities of civilization in very many ways is hard to understand; perhaps, they will consistently throw civilization overboard and get along without it. At any rate, civilized man who can not do without cooks will very probably have to contrive to exist with them for some time to come. No one will object to such extremists taking their food raw if they want to, but if they make further steps toward the simian golden age and begin to do without clothes they may have to be interfered with.

MALODOROUS THERAPEUTICS.

It is not often that a sensorially very obtrusive public nuisance is defended on sanitary grounds by medical men, but such appears to be sometimes the case, if we are to trust the newspaper reports of a recent occurrence in New York. The health officers of a village on Long Island, in support of an application for an injunction by interested parties against a dumping-ground for the city's stable refuse, described it as a menace to health, with an odor permeating the atmosphere for miles around, affecting even the slumbers of the inhabitants and ineradicably abiding in their draperies and habitations. Against this strenuous denunciation the offending contractors furnished the affidavits of two presumably prominent New York physicians. One of these, said to be a specialist in nose and throat diseases, averred, it is alleged, that he had "carefully observed the effects of the exhalations and gases arising from fermenting stable refuse upon the respiratory organs and deemed them conducive to health," and that he had advised his patients to expose themselves as much as possible to such odors and gases. A member of the offending firm was perhaps one of these patients, as he claimed that he had entered the business because he had been thus advised and his health had profited. Of course, he may have only followed lay advice, for it is well known that the notion of the salutary therapeutic effects of animal ordure in one form or another is widespread in a certain class, but we have heretofore considered it only as a very vulgar superstition. Now, that it has the sanction of a learned lecturer it is to be hoped that the laboratory of his school will soon send out some published results of researches on the subject.

QUACKERY AND THE POLITICIANS.

The osteopathy propaganda, failing in any scientific endorsements that would be impressive to the public, is sending out the alleged opinions of politicians in regard to their pseudoscience. One of the latest sent out is a selection of utterances purporting to come from eleven governors and ex-governors of several states in favor of osteopathy. One of these from the governor of Missouri is superfluous; his deeds speak louder than words and he has amply demonstrated his mental idiosyncrasies. Another, however, purports to come from Governor Tanner, of Illinois, whose record *is somewhat different. He is made to say:* "There is no doubt in my mind that osteopathy will reach and cure many chronic troubles that medicine would have little or no effect upon." This may be sarcasm, though as such it requires a little second thought to see it, and it is not taken as such by the osteopaths. Altogether, considering his previous sensible action in this matter, we will accept it as irony. One or two others of the statements quoted, if not quite non-committal, at least do not commit their makers very strongly as partisans, and may have been merely the complaisant answers of lay politicians to requests that they did not care to directly refuse. Some, however, "slop over," to use a vulgarism, like Governors McMillan and Taylor, of Tennessee, who consider osteopathy as the epoch-making discovery of the century, and ex-Governor Altgeld, of Illinois, who poses as one relieved by osteopathy while drugs and prescriptions "were as ineffectual as empty words." It is not surprising that out of the hundreds of living governors and ex-governors of states any set of quacks or system of quackery should find a short dozen of endorsers, and, of course, they are utilized to the utmost. It would not be a bad plan if the profession would keep in mind the politicians who endorse quackery; if this were done they might not be so ready to give it their good word.

THE SERUM TREATMENT OF TUBERCULOSIS.

The paper of Mircoli, abstracted elsewhere in this issue,[1] seems worthy of at least passing comment. The striking results with so large a series of cases, nearly 3000, from the use of the Maragliano antitoxin in the different forms of tuberculosis are better shown in his tabulated statements than in our abbreviated report. Over 14 per cent. of the cures added to nearly 50 per cent. of "improved" is a good showing. When we analyze the figures further and find that the disease progressed during the treatment in only about 18 per cent., and that the disease in the cases rated as improved tends to be permanently checked, it is still better. Even in the advanced cases with cavities already formed, only in about one-third was the disease still progressive during the treatment. Besides these results, which, it must be said, were attained with the additional aid of general hygiene and dietetic treatment, the paper reports other facts of great interest. One of these is that while blood-serum of the normal individual has an antitoxic action toward the tuberculous toxins and that of the tuberculous patient has not, the latter regains this after a month or so of treatment with the Maragliano serum, thus showing that the latter puts the system into a condition to assist in defending itself. If [illegible] berculin are also noteworthy. He holds that it directly increases the amount of toxins already in the organism, and in tuberculous individuals it may need "only the fraction of a gram to overthrow the already unstable equilibrium." When we remember that the use of tuberculin is being advocated by some for a diagnostic purpose, these statements are deserving of careful consideration. If we accept, with Mircoli, the views of Naegeli that practically all persons are or have been infected and still carry the latent foci in their bodies, this possibility of stirring them up to activity is a very serious one. While all the views and facts contained in Mircoli's article are not new, yet it is worthy of careful attention as an important contribution on the therapeutics of tuberculosis. Something must be allowed, however, for a possible enthusiasm in such a paper, and it may be perhaps considered as somewhat of an *ex-parte* view of the method.

---

Medical News.

CALIFORNIA.

The Spaniard who brought smallpox to Chico has died; another case has appeared, and quarantine has been established.

The Pasadena Medical Society, on September 11, passed resolutions commending the local board of trustees for its action in sewering the city.

Oakland's death-rate for August was the lowest on record, 9.76 per thousand per annum. More than 20 per cent. of the deaths were from consumption.

Dr. Junius D. Young, Stockton, was reappointed first assistant physician at the State Hospital, September 13. Under the new regulations this gives him a life position from which he can be removed only for cause.

The Gibbs Building, the first of the brick structures which are to replace the frame buildings of St. Luke's Hospital, San Francisco, had its cornerstone laid, September 19. The building will be 135 feet long, 44 feet wide and two stories and a basement in height.

Los Angeles parents are being forced to obey the vaccination law. One opponent has had his five children refused admission to school for want of certificates. The health officer is vaccinating the children by fifties and is also supplying virus and certificates to local physicians.

The quarantine officer of San Francisco, who applied for a mandamus to compel the audit of his demand for salary, has had his application denied by Judge Seawell, on the ground that the duties of quarantine officer do not extend to any part of the city and county and that efficient quarantine and inspection is already maintained at that port by the United States Marine-Hospital Service.

GEORGIA.

The charter members of the Georgia Pasteur Institute and Laboratory met in Atlanta September 21 and organized by electing the following board of directors: Drs. Charles D. Hurt, Claude A. Smith and James N. Brawner, Atlanta; Dr. Henry R. Slack, La Grange; Dr. James H. McDuffie, Columbus; Dr. St. Joseph B. Graham, Savannah; and Dr. Ernest P. Ham, Gainesville. The following officers were then elected: Dr. Henry R. Slack, president; Dr. James H. McDuffie, vice-president; Dr. Claude A. Smith, secretary; Dr. Charles D. Hurt, treasurer. The directors propose to have in connection with the institute the best equipped pathological and bacteriological laboratory in the South and expect to open before November 1.

ILLINOIS.

Dr. John E. Tuite, Rockford, has moved to Chattanooga, Tenn.

Dr. William R. Parkes has been appointed commissioner of health of Evanston, to succeed Dr. A. B. Clayton, deceased.

Dr. Henry Hatch and family, Quincy, sail for Europe on the *Campania* to-day. They expect to be gone some months.

The City Hospital is the name given to the new emergency hospital, Quincy. The health officer reported 39 deaths in the city during the month.

A suit for $25,000 for false detention and brutal treatment has been entered by Daniel W. Storms against the Illinois Eastern Hospital for the Insane, Kankakee, to which he was committed in 1898, and from which he was discharged "improved" July 3, 1899.

Chicago.

Dr. Fenton B. Turck has returned from Europe.

Dr. Moreau R. Brown has returned from the South, and resumed practice. He has associated with him his son, Dr. James M. Brown.

Dr. August F. Lemke has accepted a position in the department of didactic medicine in the Northwestern University Medical School.

Illinois Medical College held its sixth annual commencement at Handel Hall, September 27, when nineteen men and one woman received degrees in medicine.

Dr. George F. Butler, of the Alma Sanitarium, will be at the Columbus Memorial Building every Wednesday afternoon until June 1 next.

The following changes have been made in the faculty of the Chicago Policlinic; Dr. Norval H. Pierce has taken the chair of otology; Dr. J. Rawson Pennington, that of diseases of the rectum, and Dr. Otto T. Freer, that of laryngology and rhinology.

On the petition of the attorney-general, Judge Hanecy issued an injunction on September 27, restraining the officers of the Metropolitan Medical College from conducting its business in violation of the terms of its charter. The court is also asked to dissolve the corporation, which is declared to have conducted a fraudulent business and abused and violated its charter since its organization, in 1896. The basis of the petition is the allegation that the college, while advertising itself to be a legitimate institution, did not require the attendance of applicants before conferring on them the degree of doctor of medicine.

HEALTH DEPARTMENT.

There has been such a remarkable decrease in the prevalence and in the mortality of the contagious diseases since June 1 that the department has made it the subject of special study. Up to the close of May the aggregate number of deaths from the two typical contagious diseases, diphtheria and scarlet fever, was very nearly the same as for the corresponding period of last year, namely, 584 in 1899 and 557 in 1900. Between June 1 and September 22 these deaths numbered 320 in 1899 and 191 this year—a decrease of 109, or more than 34 per cent. in the last four months. The reduced prevalence of the contagious diseases is shown by the decreasing calls for disinfection. During the first five months of this year 2665 disinfections were called for, as against 1704 in the corresponding period of 1899, an excess of 36 per cent. this year. Since June 1 the proportions have been nearly reversed, 759 this year and 1099 last year, or 31 per cent. fewer.

The health commissioner has received a report from Mrs. Clara Doolittle, sanitary inspector, which shows that there are more than forty asylums in Chicago where babies are taken care of for a consideration. She condemns the manner in which most of these "baby farms" are conducted and believes that some regulation of the system should be required whereby none but suitable persons should be in charge, and a limitation would be placed on the number of children in an asylum. By these means, properly enforced, the present extremely high death-rate might be reduced materially.

The total mortality for September, despite the unusually trying weather of the month, was only slightly in excess of that of September, 1899. The uncorrected total of deaths reported up to midnight of September 30 is 1885—being 63 more than for the month last year and 94 more than the average September mortality of the previous five years. During the closing week of the month 458 deaths were reported—an excess of 18 over the previous week and of 43 over the corresponding week of 1899. The excess is mainly among infants and children, to whom the recent sudden and extreme changes of temperature have proved particularly trying. To these changes is to be attributed the increased mortality from the acute intestinal diseases, and not to the character of the water-supply. With the solitary exception of the samples collected on the morning of September 25 the water has been continuously usable or good for 23 days. The results of this good quality of the water are seen in the lowest typhoid-fever mortality for any September in fifteen years. The death-rate for the week ended September 29 was 14.05 per thousand. Of males 254, females, 204; infants under 1 year, 116; between 1 and 5 years, 66; and over 70 years, 78 died. The principal causes of death were: Acute intestinal diseases, 90; consumption, 49; heart diseases, 33; nervous diseases, 29; pneumonia, 27; violence, 17; cancer, 16; Bright's disease, 16; convulsions, 15; diphtheria, 14; bronchitis, 13; typhoid fever, 9, and suicide, 9. During the week 570 births were reported. In the laboratory 340 samples of milk and cream were examined, 8.29 per cent. of which were below grade.

INDIANA.

DR. JOHN E. OWEN, Evansville, was seriously injured in a runaway accident, September 24.

THE CENTRAL COLLEGE OF PHYSICIANS AND SURGEONS, Indianapolis, began its twenty-second annual session September 20.

DR. CHARLES HOLTZENDORFF, Plymouth, has returned, after a summer spent in his old home in Germany.

DR. ROBERT N. C. COOK, Boswell, was married to Miss Gertrude L. McClure, a trained nurse, of Vincennes, at Spencer, August 18.

DR. WILLIAM B. MCDONALD, New Augusta, suffered fracture of two ribs and injuries to the left leg and head in a runaway accident September 19.

DR. THEODORE A. HOCH, Michigan City, has gone to Worcester, Mass., to enter on his duties as house physician at the Massachusetts State Insane Asylum.

THE MEDICAL COLLEGE OF INDIANA, Indianapolis, held its entrance examination for freshmen September 25, and the fall term opened on the following day.

PROF. GEORGE W. HUFFORD, principal of Shortridge High School, Indianapolis, has been appointed by the State Medical Board of Examination and Registration to act as examiner of the literary qualifications of applicants for admission into the freshman classes of the local medical colleges.

IOWA.

THE NEW $10,000 addition to the Dallas County Hospital, near Adel, is now completed and ready for occupancy.

TWO HOSPITAL PROJECTS are under consideration in Waterloo. The first contemplates the establishment of a general public hospital open to patients of all qualified physicians and governed by a lay board of trustees. The second scheme is the formation of a stock company, composed of physicians, to build and equip a hospital. Between $5000 and $6000 has already been pledged in stock subscriptions.

KANSAS.

DR. O. PORTIS DAVIS, Topeka, was married on September 19 to Miss Mabel Glendennning, also of Topeka.

DRS. M. R. MITCHELL AND C. HAMMOND, Topeka, have opened a hospital in North Topeka called "Riverside Hospital and Maternity."

DR. JOSIAH P. LEWIS has been made professor of gynecology in Kansas Medical College, Topeka, in succession to the late Dr. S. E. Sheldon.

DR. S. B. CHILCOTE, on account of failing health, has sold his practice in Onaga to Dr. Frank W. Randall, Wheaton, and expects to settle in California or the South.

THE KANSAS STATE BOARD OF HEALTH has declared war on the Independent Medical College of Chicago, and will not permit those holding its diplomas to practice in the state.

PLANS are now in the hands of local contractors for the erection of a large private hospital in Ellsworth, to be owned and operated by Drs. Henry Z. Hissen and H. O'Donnell, of Ellsworth.

MARYLAND.

DR. CHARLES F. DAVIDSON will move from Queenstown to Easton.

THE BOARD OF HEALTH of Baltimore County met at Towson September 20 and discussed the quality of vaccin virus supplied to the vaccinating physicians, received reports of seven cases of diphtheria and decided that the secretary should receive the fee of 20 cents for the registration of each birth and death in the county.

Baltimore.

DRS. WILLIAM OSLER AND THOMAS C. GILCHRIST have returned from Europe.

DR. B. MERRILL HOPKINSON was re-elected president of the Atlantic Association of the Amateur Athletic Union at Philadelphia on September 17.

THE BALTIMORE UNIVERSITY opened October 1 with an address by Prof. J. A. Melvin on "Medical Folk Lore."

THE WOMAN'S MEDICAL COLLEGE opened October 1 with an address by Prof. Claribel Cone.

DR. G. MILTON LINTHICUM, professor of physiology and rectal surgery in the Maryland Medical College, who has been studying abroad, will return to his duties this month.

DRS. JOHN RUHRAH AND MELVIN S. ROSENTHAL, who served as resident and assistant physician, respectively, at the local quarantine station, are in Europe pursuing studies in their specialties, internal medicine and skin diseases.

MARYLAND MEDICAL COLLEGE opened for the fall session September 17. Prof. Richard L. McNeer made the introductory address. Dr. Harry Gross has been appointed professor of operative and clinical surgery and Dr. Ernest [illegible] Grande professor of chemistry and toxicology.

THE BALTIMORE MEDICAL COLLEGE opened on the evening of September 27 with an address by Prof. W[illegible] on "Medical Education from the Standpoint of the [illegible] Medical College." Dr. J. M. H. Roland has been made professor of obstetrics. Mr. Archibald H. Taylor has [illegible] chair of medical jurisprudence and [illegible] State Senator Olin Bryan.

MISSOURI.

Dr. C. Lester Hall, Kansas City, has been sued for $15,000 because, as the petition relates, he set a broken leg, and when it healed, it was shorter than the other.

Four cases of suspected smallpox were reported in one block in Kansas City, September 24.

The Eclectic Medical University, Kansas City, has been ordered by Judge Henry, of Independence, to issue a diploma to Minnie B. Lang, who had paid her fees, taken her course and complied with all legal requirements. As the state board of health had instructed this college to issue no diplomas until spring, it remains to be seen what the board's action will be when this diploma is presented with a request for a license to practice.

NEBRASKA.

The Omaha Medical College held its opening exercises September 25. Dr. William B. Ely, Ainsworth, delivered the address.

Dr. Howard M. Casebeer, Lincoln, has been appointed first assistant superintendent of the State Insane Asylum, to succeed Dr. Dearing, transferred to the superintendency of the Institute for the Feeble-Minded, at Beatrice.

Creighton Medical College, Omaha, began its seventh annual session, September 24. The opening address was made by Dr. Frank E. Sampson, Creston, Ia., on "The Evolution of Medicine."

NEW JERSEY.

The women of Asbury Park are trying to raise sufficient money to build and equip an isolation hospital for contagious diseases.

The friends and relatives of Dr. George Yardley Taylor have been apprised of his death in China. He was massacred in Pao-Ting-Fu with the Hodges and Simcoxes. Dr. Taylor was a graduate of the University of Pennsylvania and formerly resided at Burlington.

Medical inspection of schools is now proposed for Newark and Paterson. In the former city it is estimated that the cost will not exceed $1500 per year. Under the law any board of education is empowered to employ medical inspectors, fix their salaries and define their duties.

NEW YORK.

Application has been made to the State Board of Charities by the Herkimer Emergency Hospital, for permission to incorporate.

The Corning Hospital received 47 patients during the first three months of its existence. The attending surgeon for the coming quarter will be Dr. Charles W. Hayt; attending physicians, Drs. John L. Miller and Willis S. Cobb.

A hospital is to be erected in Johnstown, by Alden M. Young, New York City, who has already donated twelve lots on Pennsylvania avenue for the building. The hospital, when finished, will be presented to the city.

Dr. Edward A. Parker, Brooklyn, has been appointed junior assistant physician at the Long Island State Hospital, and Dr. James L. Devlin, Sonyea, medical interne at the Manhattan State Hospital.

Violators of quarantine in Rochester will be liable to a year's imprisonment, or both, in virtue of a section of the code which provides this punishment for violation of any rule lawfully passed by a health board. The attorney for the health department gives warning that this law will be enforced rigidly.

The Albany Medical College resumed its sessions, September 26. The introductory lecture was delivered by Dr. Hermon C. Gordinier, Troy. Dr. Andrew MacFarlane has been made adjunct professor of medical jurisprudence and physical diagnosis, and Dr. Arthur G. Root, clinical professor of diseases of the throat and nose.

Zeta Phi, Syracuse, was announced in The Journal of September 15, page 697, as the first and only medical sorority in the country. In this our informant erred, and in a recent letter asked that the correction be made that a medical sorority had existed in the West for some time. From another source we learn that the Alpha Epsilon Iota "fraternity" was organized in 1890, with chapters in several universities.

The Saratoga County Medical Association was organized at Saratoga Springs, September 28. The Code of Ethics of the American Medical Association was adopted, and a resolution was passed requesting to be admitted to the New York State Medical Association as a subordinate county association. The officers elected were: Dr. F. J. Sherman, *president;* Dr. G. F. Comstock, *vice-president;* Dr. J. F. Humphrey, *secretary;* Dr. W. E. Swan, *treasurer.*

New York State Medical Association.—The approaching meeting promises to be one of unusual interest. It will take place on October 15 to 18 in the Academy of Medicine building, New York City. Considerable interest centers in the meeting of the Council and Fellows on October 15, at which time the committee on reorganization will make its report. There will be a symposium on "Obstetrics," one on "Blood," with lantern slide exhibition, and another on "Special Surgical Tuberculosis." Many prominent men from out of the state, as well as from the state itself, will take part.

Buffalo.

The Medical Department of the University of Buffalo opened its fifty-fifth session September 24. Dr. Eugene Smith, the speaker of the evening, discussed the ethical and intellectual advantages to a city and community to be derived from a university. Dr. Frederick Busch succeeds Dr. Julius Pohlman as professor of physiology.

New York City.

Dr. Emil Mayer has been ill with typhoid fever for the past five weeks, and is still in a serious condition.

The Brooklyn Health Board has made complaint against Dr. Henry W. Haskell for failing to report a case of consumption, as required by the law, which went into effect two years ago, but until now has not been enforced.

Because he turned out a consumptive patient from the Metropolitan Hospital, Blackwell's Island, Commissioner John W. Keller suspended the superintendent, Dr. Clyde E. McDonald, for thirty days. This was done notwithstanding the statement by the acting superintendent that the hospital was overcrowded and it was necessary to let the man go.

A home for convalescents is to be established at Yonkers. Adrian Iselin, of New Rochelle, has purchased the old Hartley homestead, a pretentious colonial mansion in the outskirts of the city, and has set about remodeling it so as to provide proper accommodations for about 150 convalescents. When completed, the house will be a three-story stone structure, having a piazza on three sides, and surrounded by extensive grounds.

An interesting case of acute general emphysema has been recently observed at the Harlem Hospital. The patient was a man who had fallen from a five-story building and fractured three ribs. The fragments of bone penetrated the lung, and thus opened a channel through which the air could escape from the lungs into the cellular tissue. Within three hours the man had swollen to an enormous size, and the skin was very tightly stretched over the inflated tissues. Temporary relief was afforded by incision and massage.

The obsequies over Dr. Lewis A. Sayre were held Sept. 23 in Grace Church. Members of the medical profession and numerous lay friends crowded into the church to pay their last homage. The coffin was decorated with large floral pieces from the faculty of the medical school with which Dr. Sayre had been so long connected, and upon his breast were pinned some of his treasured decorations. The interment was in Trinity Cemetery. Dr. Sayre's will, which was filed for probate on the 25th, disposes of an estate of $50,000 in real and $3430 in personal property. The old family residence at 285 Fifth avenue will go to his two surviving children, Dr. Reginald H. Sayre and Mary Hall Sayre. He leaves to his son his medical books, instruments and specimens, and his insignia of the Order of Wasa, given him by the King of Sweden.

At a special meeting of the executive committee of the New York County Medical Association, held September 24, 1900, the following resolutions were unanimously adopted: Whereas, it is our sad duty to announce the death, on September 21, 1900, of our late associate, Dr. Lewis Albert Sayre, one of the founders of The American Medical Association, and its president in 1880; therefore, be it resolved, that we place on record our high appreciation of the valuable services which he has rendered to medicine and surgery during his long and useful life; resolved, that his daring originality, his freedom from surgical traditions, along with his unflagging enthusiasm and interest in everything pertaining to his beloved profession, constituted him a teacher of rare excellence, whose pupils will cherish his memory long after the voice of their preceptor is hushed; resolved, that we extend, in the name of the members of the New York County Medical Association, our heartfelt sympathy to the afflicted relatives, and direct that a copy of these resolutions be sent to the family and to the medical journals.

The State Board of Charities has made public a report by Dr. Robert W. Hill of his inspection of the hospitals and almshouses of the city. He urges that increased and better accommodations be provided in most of the institutions visited, and calls special attention to the lack of adequate protection against fire. He complains that there is a lack of provision for helpless and crippled children, these unfortunates being left wholly without accommodation except what may be provided by private charities. He is in favor of utilizing Blackwell's and Randall's islands permanently for the city's charitable institutions, adding that Blackwell's island is not the most suitable place for a prison. The isolation of consumptives in the City Hospital is advised. As was to be expected, he characterizes Harlem and Fordham Hospitals as utterly inadequate and unsuitable for the work they are required to do. Concerning Bellevue Hospital, the report says: "There can be no doubt that from foundation to roof it is full of the germs of disease, and this in spite of all the efforts of science to dislodge them." He thinks the old hospital should be torn down and replaced by a modern structure worthy of New York City. He suggests that, in connection with the out-door department, a bureau be established for the enrollment of applicants for work in the hospitals. This would secure a better class of help, and at the same time give needed aid to many of those discharged from public institutions.

The water famine in New York City threatens to assume serious proportions. Malaria and typhoid fever are reported as being rapidly on the increase in the Borough of the Bronx, and already there are forty fever patients in the Fordham Hospital. This hospital, which is situated on Fordham Heights, has felt for some time the full force of the scarcity of water. A few weeks ago it was reported that a surgical operation had to be deferred until evening because no water could be obtained at the hospital. For a week past not a drop of water has been drawn in the hospital buildings or on the grounds, and the needs of this institution have been met only by establishing a bucket brigade and bringing the water from a hydrant in the valley, half a mile distant. The hospital will soon have no room for more patients, and, in any case, if some relief is not obtained quickly from the water department, it will be compelled to close its doors, The water famine is equally serious in the Borough of Brooklyn.

OHIO.

The Toledo Medical College opened on September 27. Rev. F. D. Kelsey made the annual address.

Dr. Charles O. Probst, secretary of the State Board of Health, sailed for the United States September 16.

Two Canton physicians, Alonzo B. Walker and Austin C. Brant, have returned from an extended trip on the Continent.

Dr. Joseph F. Fox, New Philadelphia, has returned after a two months' absence, spent chiefly in study in London, England.

Dr. Darlington J. Snyder, Columbus, has been selected as the incumbent of the chair of psychologic medicine recently established at the Ohio Medical University.

Examinations for the freshman classes of the medical colleges of the state were held in Columbus, September 25, 26 and 27, by Profs. E. W. Coy, Cincinnati; Edward L. Harris, Cleveland; H. J. Eberth, Toledo, and Charles E. Albright, Columbus, the examiners appointed by the State Board of Medical Registration and Examination.

The Cleveland College of Physicians and Surgeons opened its fortieth annual session in its new building, September 19. Addresses were made by Rev. John B. Hillman and Dr. Charles B. Parker, dean of the college, who gave a historical review of the college and university.

The Cleveland Medical Society passed the following preamble and resolutions brought before it by the committee on hygiene: Whereas, a resolution has been introduced into the school council providing for the appointment of three medical inspectors of buildings, such inspectors to be appointed by the director of schools; and, whereas, such inspection properly belongs to the department of hygiene already established and in operation for five years, and is essentially a function of the educational rather than the executive department of the schools; resolved, that we, the members of the Cleveland Medical Society, hereby recommend that the school council give to the supervisor of hygiene a sufficient number of medical assistants, not less than two, to enable the department to more effectively conserve the health of teachers and pupils by giving more frequently practical instruction in all matters pertaining to hygiene and by more frequent and thorough inspection of the physical condition of the children and of the condition of the buildings as to heating, lighting, ventilation, cleanliness, particularly of closets, and the like.

Cincinnati.

Dr. Edwin W. Mitchell has returned from a three-months' trip in Europe.

The death-rate for the week ended September 22 was only 10.40 per thousand. The total number of deaths was 91, of which 86 were white and 5 colored; 16 were over 65 years of age, and 16 were under 1 year; 50 females and 41 males. There were 11 deaths from violence.

The plan of obtaining filtered drinking water for the use of public school children will be tried first in the new school buildings, numbering about a dozen. This plan has been used in the city hospital for several months with great success and without additional expense. It is purposed eventually to supply all school buildings with filtered, previously sterilized water.

PENNSYLVANIA.

Dr. William W. Keen returned September 25 from Europe.

The new hospital for the insane at Woodville was opened September 26.

Major George H. Halberstadt, Pottsville, brigade-surgeon, N. G. Pa., was shot at from ambush September 20 while on duty near Shenandoah, but fortunately was not wounded.

Diphtheria is still prevalent in Carlisle, and on September 24 two more houses were quarantined on account of the disease. The outbreak is attributed to a polluted spring.

Typhoid fever is said to be more prevalent than usual at Stowe, a suburb of Pottstown. On examination of the water obtained from a well it was found to be polluted and has been condemned.

Diphtheria is still prevalent in Carlisle, and on September district of Millville, near Altoona, and the State Board of Health has been asked to control matters there. Fourteen cases were found on that day, making a total of 32 cases so far reported.

A committee of the board of trustees of the State Hospital at Fountain Springs laid before the State Board of Charities the plans for the proposed addition to the hospital. They hope to secure an appropriation of $50,000 for the purpose from the next legislature. The addition is urgently needed, as the hospital has been overcrowded for several years.

Superintendent Lance, of the Spring Brook Water Company, was, on September 28, arraigned before Mayor Nichols, of Wilkesbarre, on the charge of supplying impure water to the citizens of that place. The city ordinance provides for a fine of $100 a day when impure water is allowed to run through the mains. Dr. Walter Davis, the city inspector, had pronounced the water unfit for domestic purposes.

Philadelphia.

Dr. W. W. Keen has returned from his trip to Europe.

Dr. Harry W. Cattell has gone to Europe for a few weeks vacation.

Through the bequest of Emmeline Macurdy, who died at Mt. Holly, N. J., recently the sum of $5000 has been left the Episcopal Hospital.

Dr. Horatio C. Wood, who has been for the past three months in Japan, arrived home on September 24, bringing with him a large collection of curios.

The president of the Free Hospital for Poor Consumptives reported that during the first six months of the year, 116 patients were cared for, at an expense of $4584.97. It now has 31 patients under its care.

The fall sessions of the Medico-Chirurgical and of the Women's Medical College have begun. At the Women's Medical College the chair of surgery has been divided into surgery and clinical surgery.

The number of deaths which occurred during the week ended September 29 was 347, a decrease of 9 over that of last week and is less than the corresponding periods of the last three years. The principal causes of death were: Apoplexy, 14; nephritis, 31; cancer, 19; cholera infantum, 12; tuberculosis, 51; heart disease, 19; pneumonia, 12; peritonitis, 6; septicemia, 5; and diphtheria, 10.

Jefferson Medical College opened on October 1. The total enrollment shows an increase of 100 over that of last year and makes a total of 700. The principal addresses were delivered by President William Potter and Prof. Francis X. Dercum. Only one change has been noted in the faculty, that of Dr. H. F. Harris, who was formerly associate professor of pathology, but has resigned to accept the chair of pathology in the Atlanta (Ga.) Medical College.

Victor B. Hall, of London, Ont., has been on trial in that city, charged with causing the death of a woman by withholding from her medicine which should have been given during her last illness, but was finally acquitted. He formerly lived in this city, was the founder of what is known as "The Vital Friends," and was known in his neighborhood as the "Doctor of Vital Science." According to his teaching all diseases are due to indiscreet eating, and can be cured by a proper diet.

The University of Pennsylvania opened its one hundred and sixtieth annual session on September 28. The medical department began its session on October 1. Several changes have been made in the faculty since the last term: Dr. William J. White becomes John Rhea Barton professor of surgery; Drs. Edward Martin and Charles H. Frazier become professors of clinical surgery; Dr. J. Francis Walsh has been appointed prosector to the professor of anatomy; Drs. Brooke M. Anspach, instructor in clinical gynecology; Collins C. Stewart, demonstrator of physiology; Richard M. Pearce, demonstrator of pathology, and William F. Hendrickson and Frederick H. Howard, assistant demonstrators of pathology. A new system of instruction has been inaugurated in the first and second year classes in both the medical and dental departments. Under the new system anatomy will be taught the first year, while the whole of physiology will be completed in the second year. Materia medica and therapeutics, which were formerly taught in the first and third years respectively, will be changed so that materia medica will be taken up in the second year, and therapeutics the third year.

Professor Joseph Leidy, the celebrated anatomist and naturalist, was especially famous for his skill in the study of animal parasites. His discovery in 1846 of the trichina spiralis in the hog, and the subsequent association of the disease now known as "trichinosis" with this infected pork, brought him an international reputation as a helminthologist. A consequence of this was a large correspondence from all parts of the country in regard to parasitic worms. His correspondents were not always careful and trained observers, and though considerably annoyed, he was at the same time greatly amused by some of the "specimens" sent to him for diagnosis. At one time he was sent a peculiar "worm" vomited by a child in Washington, D. C., that proved on examination to be the undigested fiber of an orange. A particular instance of his ready wit is seen in the following anecdote: Some years ago he was sent a specimen, believed to be a segment of a tapeworm, that had been passed by a woman with a history of progressive emaciation, and who had not improved under feeding with highly nutritious foods and juices, and the administration of tonics. Dr. Leidy sent word that the segment passed was that of a tape-worm, but of an unusual type, and, moreover, that it was more than likely that the physician himself was responsible for the lodgment of the parasite. This most extraordinary statement brought a speedy visit from the physician in question. Dr. Leidy explained that the parasite resident in the bowel of the patient was of the species *tænia saginata,* which commonly infests beef, and he had inferred that the most likely mode of infection in the case was in the administration of the juice of raw beef, which was commonly prescribed to invalids at that time. The physician at once acknowledged the truth of Dr. Leidy's supposition, and never ceased paying tribute to his keen wit.

TEXAS.

The situation at Galveston has so improved that the State Board of Health, which has been in almost continuous session, adjourned indefinitely September 21.

The Dallas Polyclinic and University has been incorporated by Drs. Samuel E. Milliken, Jesse B. Titterington and Lawrence Ashton, with a capital stock of $3000. The object is the establishment of a school of medicine and surgery, and a dispensary.

Dr. Levingston L. Shropshire, San Antonio, proposes to remove the debris from Galveston, by pressing 2000 convicts into the work, who, he says, can do as much work as 5000 ordinary laborers. Meanwhile, convictless, Galveston is being cleaned.

Arrangements have been perfected for the immediate repairing and refurnishing of the medical college at Galveston, recently injured by the storm. The session will be opened Thursday, November 15, and will close Saturday, June 29, 1901. A careful consideration of the situation enables the Board of Regents to announce that the college will be opened on the above-named date with the same faculty as heretofore.

WISCONSIN.

The Washburn Hospital is nearly completed and will soon be ready to receive patients.

Smallpox is reported to exist in epidemic form in six of the large lumber camps in the northern part of the state.

The hospital at Merrill was opened September 22 under the direction of Dr. Michael Ravn, and was filled with patients on the first day.

Menasha is threatened with an epidemic of diphtheria. On September 26, 7 new cases were reported. During the previous month 17 cases with 13 deaths occurred. Oshkosh also fears an epidemic of diphtheria.

The hospital built by Dr. Horace M. Brown, Milwaukee, has passed into the hands of the superintendent of the Wisconsin General Hospital. It will be repaired, equipped and opened as a general hospital.

The Madison Hospital Association has decided to accept the offer of Mrs. Wayne Ramsay of a tract of four acres at Greenbush, for a new city hospital. The offer is conditioned on the erection of a hospital within two years. The directors are now making efforts to raise the $10,000 required for the construction of the building.

Osteopaths in Milwaukee have been arrested on warrants sworn out by the assistant district-attorney, acting under instructions from the State Board of Medical Examiners. The charges preferred are the unlawful use of the title of doctor and the practice of medicine without a license from the state board. The osteopaths propose to contest and make this a test case.

CANADA.

The Provincial Board of Health of British Columbia has issued a proclamation to the profession in that province regarding precautions to be taken in connection with the introduction of bubonic plague. It requires all physicians to notify their city and municipal health officers of any and every disease appearing among Chinese and Japanese residents, within six hours from the date of call.

Reporting on the offer of the National Sanitarium Association of $20,000 toward a free Consumption Sanitarium for Toronto if the city would contribute an equal amount, Dr. Sheard has advised the board of health to recommend to council its acceptance, provided the municipal act is complied with.

The Provincial Board of Health of the province of Quebec has taken prompt measures to offset any probability of the plague reaching and obtaining a foothold in that province, from Glasgow or elsewhere. Five hundred bottles of antipest serum have just been received from the Pasteur Institute at Paris. All vessels that can not produce a clean bill of health, or where anything suspicious is noted, will be detained at Grosse Isle until twelve days have elapsed from the time at which they set out from the port of embarkation.

During the progress of the meetings of the Canadian Conference of Charities and Correction, which assembled in Toronto the past week, Dr. Gilbert Gordon, president of the Toronto Medical Society, read a paper on the "Treatment of Inebriates," giving a very lucid description of the proposed legislation to be introduced into the Ontario legislature at the coming session. The details of this measure have already appeared in the columns of The Journal. At the conclusion of this convention, three medical men were elected to prominent offices therein: Dr. W. L. Herriman, Lindsay, president; Dr. A. M. Roseburgh, Toronto, Secretary; and Dr. J. T. Gilmour, Warden of the Central Prison, Toronto, chairman of the executive committee.

Dr. Montizambert, director-general of public health, has returned to Ottawa after an extended trip of inspection to Dawson, British Columbia and other points West. He will at once take charge of the situation created in Canada by the existence of bubonic plague in Glasgow. Referring to his tour of the Yukon and the West, which was taken to inspect the quarantine stations in British Columbia and along the United States boundary line, as well as to report on the outbreak of smallpox at Dawson, he says he found seven cases of the latter disease quarantined down the river from Dawson, and that there had not been reported a single new case since July 20. On his return to the Pacific province from the Yukon, he inspected the quarantine station at William's Head, which he found thoroughly equipped. The medical officers along the frontier of the tier of northern states from Montana westward, he found had been exceedingly vigilant in keeping out of Canada suspected cases of smallpox, so much so, that in his opinion, inspection of incoming trains was now no longer necessary.

FOREIGN.

The Leopold Order of Knighthood has been conferred on Prof. R. Chrobak, of Vienna.

Professor Gegenbaur of Heidelberg is to retire in April. Max Fürbinger, now at Jena, has been appointed his successor.

Krafft-Ebing, of Vienna, and Eulenburg, of Berlin, editor of the *Deutsche Med. Woch.*, each celebrated his sixtieth birthday in August.

Dr. C. L. Schleich, the inventor of infiltration anesthesia, has been placed in charge of the Gross-Lichtenfelder Hospital at Berlin, with the title of professor. He has never been connected with the faculty before.

Max Nitze, the inventor of cystoscopy, has been appointed to the newly created chair at Berlin of diseases of the urinary passages. This is the first time that urology has been thus distinguished at a German university.

A meeting of over a hundred members of the Italian legislature was held recently at Rome with Baccelli presiding, and resulted in the determination to erect people's sanatoria for consumptives in different parts of the country, all to bear the name of King Humbert and be under the special patronage of Queen Margherita. A committee of thirty members was appointed, which set to work at once to carry the resolutions into effect.

The survivor of the united twins illustrated in The Journal of September 16, 1899, has been taken to Europe. As mentioned recently, Chapot-Prevost performed the operation to separate the xiphopagi, which Alvaro Ramos had declared impossible, when, on incision, he found that the twins had but a single liver between them. One of the twins died a few days after the separation. The operation had been preceded by a long systematic constriction of the uniting tissues as a preliminary measure.

Female medical students have been admitted to the German universities this year and 618 have attended the lectures, but only nine have thus far entered as regular students. The women are even favored above the men at present, as certain work at a foreign university is credited to them in the state examinations. In Austria the authorities have decided to admit women also, on the same terms as men in every respect, with the new scholastic year. Among the 850 students at Zürich, 214 are women and 128 of these are studying medicine.

None of the personnel of the seven Red Cross ambulances sent into the haunts of malaria in Italy have contracted the disease, owing, it is supposed, to the precautions against mosquitoes. They have had occasion to treat 1772 patients, including 1329 with malaria, in their rounds through the Roman Campagna and Tuscan Maremma, where the workmen have been gathering in the harvest. The experiments instituted on three railroad lines have been equally successful in proving that protection against mosquitoes is practically synonymous with immunity against malaria in most cases.

LONDON LETTER.

INVESTIGATION OF TYPHOID FEVER AND DYSENTERY IN SOUTH AFRICA.

The government has dispatched an important commission of experts to investigate the nature, cause and prevention of dysentery and typhoid fever, which has been so fatal among the soldiers in South Africa. The commission consists of Dr. W. J. Simpson, professor of hygiene in King's College, London; Professor Notter, of Netley, and Major Bruce, R.A.M.C. Professor Simpson is a distinguished Aberdeen man, of which town he was medical officer of health for five years. His attainments as a sanitarian speedily became known, and he has served on several important commissions. In 1883 he went to Egypt and reported to the government on the cholera epidemic. In 1886 he was appointed medical officer of health for Calcutta, a post which he held with conspicuous success for eleven years. The government, against the advice of Sir Walter Foster, in the first instance refused to appoint a sanitary commission to assist the army medical staff in the prevention of epidemics in the South African campaign, but has now appointed one to investigate the epidemic which has been so extensive and so disabling to the troops.

THE GLASGOW PLAGUE.

There are now 24 cases of plague in hospital, and 2 suspected cases, and 28 persons are being kept under observation. Three deaths have taken place in hospital and 3 outside. The local government board have issued an order requiring the immediate notification to the local sanitary authorities of all cases of plague which may occur in England. The order also requires the sanitary authorities to send circular letters to all the medical practitioners in their respective districts informing them of their duties under the regulations, and it imposes on every medical officer of health the duty of forthwith reporting to the board any case of plague notified to him. The Dublin corporation, as a precaution against the plague, have established an isolation hospital at some distance from the city. It is fitted up with 24 beds, which can easily be increased to 100. As to the progress of the Glasgow outbreak from September 10 to 14, no fresh cases occurred. Then on the 15th a fresh case occurred in a ward-cleaner in the hospital. On September 17, 5 other cases were reported. Four of these occurred in a family which had been in contact with previous cases, and the patient in the fifth was the wife of a worker in the hospital. Yersin's antiplague serum has been used and appears to have had a distinctly beneficial effect. The dose was 40 c.c. subcutaneously injected. All the cases seem to have originated from those which occurred first in one house, but whence the contagion has been derived is still a mystery.

THE HOSPITAL COMMISSION.

Very important evidence has been taken by the hospital commission in South Africa. Sittings have been held at Bloemfontein, where General Kelly-Kenny paid a tribute to the conduct of the orderlies, who did a great deal of work in addition to their own. They even carried a number of Boer wounded across a river, wading up to their arms, which was a purely voluntary service. The most important evidence was that of the commander-in-chief, Lord Roberts. He said that on entering an unknown, sparsely populated and hostile country, it was absolutely necessary to take large food-supplies, and the number of mules and horses and the amount of forage for these were limited. Rapid movement was possible only by cutting down the equipment of the field hospital and other details, as every day's delay put more heart into the enemy. The whole question was one of limitation of transport and the first consideration was the supply of food and ammunition. In Bloemfontein everything possible was done for the care of the sick and an unlimited order was given to commandeer everything obtainable. The enormous difficulties were shown by the fact that from March 13, when Bloemfontein was reached, till March 28 not a single truck was able to cross the Orange River. For 16 days, therefore, there were no supplies, and but few medical comforts. From March 29 till April 7 the trucks sent to Bloemfontein were 105 less than the number required to supply the food actually necessary. The troops were only just fed, and not one day's reserve was accumulated. At Kroonstadt everything obtainable was commandeered, and ladies came crying that mattresses and beds were taken from under them. Lord Roberts thought that no blame attached to the home authorities in reference to the supply of military stores and equipment. The campaign had been an extraordinarily difficult one from the hospital point of view. In his opinion the Royal Army Medical Corps, assisted by the civilian surgeons had met the difficulties magnificently. Lord Kitchener declared that the cutting down of the hospital transport under the order of January 29 was absolutely necessary in order to quickly relieve Kimberly. The problem was what could be carried with the number of mules available. He deprecated placing the transport altogether in charge of the field hospitals. Surgeon-Gen. Stevenson explained that the men had to lie in the field hospitals in their khaki uniforms, as no provision was made for supplying the field hospitals with clothes. In Bloemfontein everything was taken that was capable of being worked by the personnel. He admitted that there was a shortness of utensils, milk, bedding, etc., and overcrowding of the general hospital. There was also, for a short time, a lack of drugs and utensils in Kroonstadt and Pretoria. He had permission from Lord Roberts to purchase everything obtainable, and he spent several thousands of pounds.

LONDON'S LUNATICS INCREASING.

The annual report of the county council shows that there are more pauper lunatics in London than ever. The only consoling feature is that the rate of increase last year was not so great as usual. At the beginning of this year the number of lunatics was 21,393 against 21,060 last year. There is a high proportion, 1 in 6, of mania from alcohol and more than double the number of women than men have been admitted from this cause. It is found that women relapse and are readmitted with greater frequency than men. Drink was a more prolific cause of insanity than hereditary taint, and much more so than "business worries," "love affairs," etc. Single patients outnumbered the married. This last year the admissions were 1804 married, 2063 single.

Correspondence.

A New Remedy for Whooping Cough.

Calumet, Mich., Sept. 24, 1900.

To the Editor:—In the *Berliner Klinische Wochenschrift* for Dec. 11, 1899, appeared an article by Dr. Max Heim, of Düsseldorf, in which he recounted such successful results in the treatment of pertussis with a new remedy, "antitussin," that I was impelled to obtain a small amount of the remedy for trial. The results of this trial are, I think, sufficiently interesting to be worthy the notice of those who may not have seen Dr. Heim's original article or any abstract of it. It is an ointment, consisting of 5 parts difluordiphenyl, 10 parts of vaselin and 85 parts of lanolin, and is administered by inunction. The back, chest or abdomen of the patient is thoroughly washed with warm soap and water and rubbed dry with a rough towel. On the skin thus prepared the ointment is applied, a small portion at a time, and rubbed in until the greasy feeling has disappeared. This usually requires from twenty minutes to half an hour. The amount applied at one time varies with the age of the patient; for a child a year old I used a quantity of the ointment as large as the end of my thumb, and for one 5 years old about twice as much. I think, however, that slightly larger amounts would give still better results. I have treated six cases in all, and have been furnished with the data of one other, which was treated by my associate, Dr. Bourland. These ranged in age from four months to six years. In all of them the treatment was not commenced until the paroxysmal stage had been reached, and in most of them this had proceeded about two weeks. In general, the cases were treated in the manner above described daily for the first week, and thereafter every other day until the conclusion of the case. In all an immediate improvement was noted from the very first application of the ointment. The number of the paroxysms rapidly diminished. In four of the cases in which an accurate count was kept of their number, they diminished as follows: In Case No. 1, from 16 paroxysms on the first day of treatment to none on the thirteenth; in Case No. 2, from 27 on the first day to none on the thirteenth; in Case No. 3, from 18 on the first day to none on the sixteenth; in Case No. 4, from 25 on the first day to none on the fifteenth. In another case in which very severe paroxysms, though few in number, had existed for over a week, there was not a single severe additional attack after the first application of the remedy, and the attacks entirely disappeared after the fourth application. In one of the cases there was a relapse about a week after a cure seemed to have been effected.

The severity of the paroxysms, as well as the number, rapidly diminished from the time of beginning the treatment. They were neither so long nor so exhausting; the vomiting which usually followed them became less frequent and the children improved in appetite and in getting their normal amount of sleep. At night the greatest improvement seemed to be manifested. *In fact, from the beginning of treatment, the patients all steadily improved, and progressed to a complete recovery, save in the one case of relapse mentioned. They were receiving* no other medication during the time of this treatment. The patients all seemed to take kindly to the method of medication, and the younger babies in particular seemed to get a great deal of pleasure out of the process of inunction. In no case were any unfavorable symptoms, visceral or otherwise, observed which might have been due to the use of the remedy.

In a disease like pertussis, for which so many remedies have been proposed, and most of them untrustworthy, any one which approaches the nature of a specific would be given a hearty welcome. While my limited experience with the remedy does not warrant my making any too extravagant statements concerning it, I do feel justified in expressing the belief that it is of great value in pertussis, and well worthy of a trial by any who are called on to treat this disease.

Frederick T. Wright, M.D.

The Kernel of Listerism.

Fort Reno, Okla., Sept. 21, 1900.

To the Editor:—Your editorial entitled "Pathologic Asepsis" on page 691 of The Journal of Sept. 15, 1900, helps to answer the query: What, after all, does the good residuum consist of when Listerism has been boiled down, filtered, and, in general, freed from all extraneous and worthless ingredients? That there will be a good residuum is beyond doubt. It has long been known that germs are necessary for digestion, for producing fermentation, and for bringing about useful decay of dead bodies, vegetable or animal. In other words they promote progress. The best garden-soil reeks with germs, poisonous and non-poisonous. Sterilized soil plus sterilized water will bring forth nothing, whether sown or not sown. Your editorial implies that, without the little organisms, wounds will not heal. In other words, life—for germs represent; and the word "germ" primarily means, life, or the first principle—is needed everywhere we wish to maintain or to increase life. Furthermore, wounds not infrequently healed by first intention before asepsis was dreamed of; and during the last few years in Cuba, the Philippines and South Africa, it seems to have been the rule rather than the exception that the simpler wounds healed that way—and certainly asepsis or antisepsis was not usually carried out—could not be, in fact.

But cleanliness was enforced. Gross handling, the application of dirty substances, and the probing with dirty instruments, was not allowed. In most cases a clean bandage was immediately placed over the wound—though the latter was but imperfectly cleansed—and kept there.

Is it not entirely pertinent, then, to ask: Does not the condensed extract of Listerism—the solely useful part to the patient—consist merely in the cleanliness involved? It would appear that had surgery forty years ago been the cleanly art it is to-day Listerism would never have seen the light. The old saying, "cleanliness is next to godliness," receives new force.

Very respectfully, J. D. Poindexter, M.D.,
Capt. and Asst.-Surgeon, U. S. Army.

Deaths and Obituaries.

Jesse W. Lazear, M.D., U.S.A., who died from yellow fever in Quemados, Cuba, September 26, was born in the suburbs of Baltimore, in 1866. He took a course of study and his B. A. degree at Johns Hopkins University, and his M. D. degree with honors at the College of Physicians and Surgeons, New York, 1892. He served as interne for two years in Bellevue Hospital and then went to Germany for a year to pursue special studies in bacteriology. In 1895 he became demonstrator of clinical microscopy in Professor Osler's service, and one of the house physicians at Johns Hopkins hospital until the spring of 1900, when he entered the Medical Department of the Army as acting assistant-surgeon. He was at once assigned to duty at Quemados, Cuba, made a member of the board appointed for the study of yellow fever, and placed in charge of a laboratory at that place. His work since then can be best described by quoting from the letter sent to the surgeon-general of the army, by the chief surgeon, department of western Cuba: "Dr. Lazear has for the past four months exposed himself with absolute fearlessness in the discharge of his duties. He has examined the blood of every case of yellow fever which has occurred at Columbia barracks and in Marionao during that time; has immensely aided in the making of prompt diagnoses, which has been so important an element in our preventing the spread of the disease and in the success of the treatment of our cases. In the investigations of the board he has shown the same courage, earnestness and ability which characterized all his work. Dying at the age of 34, he leaves a wife and two children, the youngest of whom he never saw, as his son was born in the United States while he was in Cuba this summer."

Preston Brown Scott, M.D., died in Louisville, September 24, of typhoid fever contracted while at Mount Clemens, Mich. He was born in Frankfort, September 12, 1832; his father was the first school commissioner in Kentucky, and on his own farm in 1841 erected the first public school, and there Preston Scott, when 9 years of age, became enrolled as the first public-school pupil in Kentucky. He was graduated from Georgetown College in 1849; from the medical department of the University of Louisville in 1856. He settled in Hickman County, Ky., but later removed to Bolivar, Miss. When the war broke out, Dr. Scott was appointed surgeon in the 4th Kentucky Infantry, C.S.A., was promoted to brigade surgeon under Gen. Ben Hardin Helm, and later was transferred as surgeon to the staff of Gen. Jos. E. Johnson at Jackson, Miss. At the conclusion of the war Dr. Scott went to Louisville, where he practiced continuously, enjoying one of the largest general practices in the city. He was possessed of a particularly broad and versatile mind, and kept thoroughly abreast with the times. He was one of the medical directors of the Episcopal orphanage and was physician in charge of the Masonic Widows' and Orphans' Home. At the last meeting of the Confederate veterans in Louisville he was elected president of the Surgeons' Association.

James Hart Curry, M.D., of Shrub Oak, N. Y., where he had been in practice for nearly fifty years, died there September 24. He was born in New York City in 1827 and was graduated in 1852 from Yale Medical College. At the time of his death he was the oldest member of the Westchester County Medical Society, in which he had held every office. During the Civil War he served as surgeon of the 18th N. Y. Volunteer Infantry, and subsequently on the staff of the 5th Division, N.G. S. N. Y.

James Willoughby Phillips, M.D., superintendent of the Burn Brae Sanatorium, Clifton Heights, near Philadelphia, died September 20, aged 53 years. He was born in Montreal, attended the University of Toronto, and afterward studied medicine for three years at Guy's Hospital, London. He obtained his M.R.C.S. in 1874. He came to Philadelphia in 1876, and was a member of the College of Physicians and various medical societies.

Samuel N. Pierce, M.D., a graduate of Vermont Medical College, Woodstock, surgeon of the 13th Iowa Infantry in the Civil War, and one of the oldest physicians as regards length of practice in Iowa, died at Cedar Falls, September 23, from paralysis, aged 68 years.

J. F. Moser, M.D., while burning brush on his farm near Silverton, Ore., was pinned down by a falling tree and burned to death, September 13. He was 44 years of age, a graduate of Willamette University medical department, Salem, and had served as physician at the Warm Springs Indian Agency.

James A. Paddock, M.D., a native of Princeton, Ill., a graduate of Bellevue Hospital Medical College in 1874, one of the pioneer physicians in the Black Hills and surgeon to the Burlington Railroad, died suddenly from apoplexy at his home in Deadwood, S. D., September 16, aged 52 years.

Reuben Swartz, M.D., who died suddenly in Lebanon, Pa., September 16, was born in Hancock in 1842, was graduated from the Medico-Chirurgical College, Philadelphia, and practiced in Myerstown until 1882, when he moved to Lebanon.

Robert F. Forrest, M.D., a native of Watertown, Mass., and a graduate of Harvard Medical School in 1898, died at his home September 18. After his graduation he practiced in Cambridge until last June, when he was obliged to go to Colorado for his health.

W. Scott Wolford, M.D., Philadelphia, died of nephritis after a long illness, September 18, aged 53 years. He was graduated with honors from Jefferson Medical College in 1873, practiced in Philadelphia and was coroner's physician for a time.

Henry B. Wilson, M.D., a native of Boonboro, Md., who had practiced for ten years in Omaha, Neb., died near Aberdeen, Harford County, Maryland, September 20, aged 35 years. He was graduated from the University of Maryland in 1889.

Jesse H. Naftel, M.D., county physician of Montgomery County, Alabama, died suddenly from heart disease at Montgomery, September 17, aged 39. He was graduated from the Medical College of Alabama, Mobile, in 1887.

George A. Breckenridge, M.D., St. Joseph, Mo., who was graduated from the Central Medical College in that city last year, died at his home, south of Stewartsville, Mo., September 19, aged 30.

James R. Powell, M.D., Tipton, Ind., was found dead by the roadside, five miles from his home, September 21. He was graduated from the Central College of Physicians and Surgeons, Indianapolis, in 1894.

J. Herbert Ellis, M.D., one of the successful contestants for an interneship at the Cincinnati Hospital, died at Asheville, N. C., September 25, of pulmonary hemorrhage. He would have entered upon his duties at the hospital October 10.

Thomas Bailey Lewis, M.D., Turnersville, Ky., a graduate of the College of Physicians and Surgeons, New York, in 1859, and surgeon of the 6th Kentucky Cavalry, C. S. A., died from phthisis, September 16.

Otis K. Chamberlin, M.D., who was graduated from Albany Medical College in 1845, died September 20 at Dayton, Ohio, where he had practiced for many years, aged 84.

DEATHS ABROAD.

Prof. Eduard Albert, whose fame as a surgeon, teacher, lecturer and medical writer is world-wide, died in Vienna, September 26, aged 59. He was born in Bohemia, studied in Vienna, became assistant in the surgical clinic in 1867, professor of surgery at Innsbruck in 1873, and in 1881, after the death of Damreicher, assumed the chair of surgery. Students in Vienna used to attend Albert's lectures and Billroth's clinics. As a lecturer he was unsurpassed. His knowledge of the literature was remarkable. Among his pupils are such men as Hochenegg, Lorens, Maydl, C. Ewald, Hobart and Ullmann. He demonstrated before the International Medical Congress in August the architecture of the long bones, showing how their construction is regulated by the same laws that man has laboriously evolved in the architecture of bridges, etc., to ensure support and strength. His "Lehrbuch der Chirurgie" was the first manual to appear inspired by antiseptic principles. His works include several on the history of medicine and surgery, and on the treatment of various surgical affections. Among his contributions to science may be mentioned his artificial ankylosis for flail-joints, tenopexis, osteoplastic method of neurectomy of the mandibularis, and arthrectomy synovialis. He was the first to make a transplantation of the nerves on man, and to call attention to sciatic scoliosis and to painful papilloma of the tongue.

Dr. J. A. de los Rios, professor of therapeutics, died at Lima, Peru, July 25. He was president of the Medical "Union Fernandina" and formerly editor of *La Cronica Medica.*

Miscellany.

MARINE-HOSPITAL NOTES.

IMMIGRATION STATION AT HAVANA.

The prevalence of yellow fever in Havana this summer, mainly among recent non-immune arrivals, has suggested to the Governor-General of Cuba the advisability of establishing a camp outside of the city of Havana where non-immune immigrants may be detained pending their distribution among the plantations of the island, thereby avoiding contact with infected foci in the city of Havana. A board has already been appointed for the purpose of carrying this idea into effect. The site recommended by the board is on the hills some distance back of Triscornia, a place across the harbor from Havana proper. Large, comfortable and well-arranged barracks are to be built. On arrival of a vessel with immigrants, she will be boarded and inspected as usual by a medical officer of the Marine-Hospital Service, and then all immigrants not disqualified at this inspection will be sent to Triscornia and from there passed on to the immigration station. There the immigrants will be cared for until they can be safely transported to the country districts. Heretofore these immigrants have entered the city of Havana and lived sometimes for weeks in the overcrowded and infected districts while awaiting employment. It is contemplated that a medical officer of the Marine-Hospital Service will be detailed in charge of this immigration station.

THE GALVESTON FLOOD.

Surgeon Peckham, in charge of the Marine-Hospital Service at Galveston, Tex., has written an interesting report on the tornado, detailing the facts, which are corroborative of the press dispatches. He places the loss of life at more than five thousand, and states that 500 dead bodies drifted ashore at Virginia Point. He has been nearly over the island and has not seen a house that was not damaged. The aerometer at the weather bureau broke down when eighty-four miles an hour was reached, and it is estimated that 100 miles an hour was the velocity of the wind at one time. Water was over the whole island; at the highest point of the island the water was 5 feet deep. At the house where he boarded the water was 7 feet deep. He was instrumental in saving seventeen persons, and, immdiately after the storm, began the work of furnishing surgical relief. At the request of the local board of health, Surgeon Peckham established two camps intended for the care of sick and homeless, and had to assist him P. A. Surgeon Wertenbaker, Sanitary Inspector Lea Hume and Hospital Steward Peck. The material for the camps was taken from the contributions so generously sent in. It is understood that they are now used simply as refuge camps under the local authorities.

STATUS OF BUBONIC PLAGUE IN GLASGOW.

The latest reports received from the medical officer of the Marine-Hospital Service on duty in Glasgow show that there have been a total of thirteen cases to September 7. There have also been one or two cases in the suburbs of Govan. The authorities have defined a wide area about the houses where the original cases occurred and special sanitary supervision is exercised inside of this line. The infected premises have been cleaned, fumigated with sulphur and the walls and floors washed with carbolic acid solution and whitewashed. All infected clothing and bedding has been steamed or destroyed. The medical officer and his assistant have been inoculated with Yersin serum, as they have been exposed to the disease. They are inspecting all vessels, their cargoes and passengers leaving for the United States or Canada. Dr. Thomas states that the crews are the most dangerous and difficult feature, but that every facility is being given by the officers of the various vessels in their inspection and in all the precautionary measures.

Suturing the Sigmoid Flexure to the Bladder in Gynecologic Operations.—There are no means of covering the raw surfaces left after removal of extensive portion of the peritoneum in certain operations on the small pelvis. Amann stated at the International Medical Congress that he remedies this by drawing forward the sigmoid flexure and fastening it to the posterior surface of the bladder. The meso-colon is thus stretched across above the small pelvis, completely isolating the field of operation from the large abdominal cavity. Supplemented by drainage into the vagina it enables the peritoneum to be resected with comparative impunity. The procedure is harmless, with no inconveniences of any kind, and is proving a new and valuable resource in pelvic surgery, as Jonnesco confirmed from his experience.

Therapeutics.

Carbolic Acid in Mastoiditis.

W. C. Phillips, in *Med. Record,* states that he has found carbolic acid to be without a peer in treatment of suppurative conditions about the ear. He applies it with a cotton swab or with an atomizer, and permits it to remain for thirty or sixty seconds and neutralizes it with alcohol. With this treatment unhealthy granulations become normal, the discharge ceases and often operations are avoided.

Rub each ingredient separately, and then together in an earthen vessel and finally add the solution of zinc chlorid drop by drop.

The above paste is by Bougard, and is said to be superior to Marsden's preparation for the removal of superficial epithelioma. —*Am. Jour. of Surg. and Gyn.*

Mumps—Parotitis.

℞. Icthyolici			
Plumbi iodidi, āā	gr. xlv	3	
Ammonii chloridi	gr. xxx	2	
Adipis	℥i	32	

M. Sig. Apply to the parotid gland three times a day.

—*Interstate Med. Journal.*

Scabies and Prurigo.

℞. Epicarin	ʒii	8	
Cretæ alb.	gr. xxx	2	
Vaselini alb	℥i	32	
Lanolini	℥ss	16	
Adipis	℥iss	48	

Pfeiffenberger, in *Klin. Ther. Woch.,* recommends the above containing epicarin in treatment of scabies and prurigo in children. —*Therapist.*

Lotion for Burns.

Dr. Nikolsky, in *Journal de Méd. de Paris,* recommends the following:

℞. Acidi tannici			
Alcoholis, āā	ʒii	8	
Etheris sulphurici	℥ii	64	

M. Sig. Use as a local application.

—*N. Y. Med. Journal.*

Goiter.

℞. Hydrarg iodidi rubri	gr. x		06
Atropinæ sulphatis	gr. ss		03
Unguenti simplicis	℥i	32	

M. Sig. A piece the size of a pea to be well rubbed into the skin over the tumor two or three mornings in succession, and then repeated once a week. —*Alk. Clinic.*

Lumbago.

℞. Linimenti camphoræ	ʒxii	48	
Olei terebinthinæ	ʒii	8	
Saponis mollis puræ	ʒiv	16	

M. Sig. Rub the parts well night and morning.

—Gould and Pyle.

Ringworm of the Scalp.

The following outline for treatment of ringworm is laid out by Jamieson, in the *Edinburgh Med. Jour.*:

1. Shave the hair from the scalp.
2. Keep the scalp clean by washing twice a day with soap and warm water.
3. Apply the following ointment:

℞.	Sulphuris precip.			
	Acidi salicylici			
	Betanaphtholi			
	Hydrargyri ammoniati, āā	gr. x		66
	Lanolini, q. s.	℥i	32	

M. Sig. To be rubbed into the scalp thoroughly twice a day.

—*Exchange.*

Rheumatoid Arthritis.

According to *La Presse Médicale,* Dr. Mussey employs the following ointment, with asserted good results:

℞.	Ext. belladonnæ			
	Ext. hyoscyami			
	Ext. conii			
	Ext. opii, āā	gr. xv	1	
	Adipis	℥ii	64	

M. Sig. Apply locally night and morning.

—*Ther. Gazette.*

Emetic for Children.

℞.	Pulv. ipecacuanhæ	gr. viiss		5
	Antimonii et potassii tartratis	gr 1/6		01
	Aquæ destil., q. s. ad	℥i	32	

M. Sig. One teaspoonful every ten minutes until vomiting is produced.

Shingles—Herpes Zoster.

℞.	Ichthyolici			
	Magnesii carbonatis			
	Zinci oxidi, āā	ʒii	8	
	Aquæ destil., q. s. ad	℥iv	128	

M. Sig. Spread over the affected part and cover with a *bandage.*

Ichthyol—5 per cent.—in collodion may be used, and where rheumatism is present the salicylates may be given in large doses.

—Lusk: *Postgraduate.*

Loss of Hair.

Baril, in *Jour. de Méd. de Paris,* recommends the following application for the arrest of the falling of hair:

℞.	Acidi hydrochlorici	m. lxxv	5	
	Alcoholis	℥v	160	

M. Rub the scalp well every night with the solution.

—*N. Y. Med. Journal.*

Constipation in Women.

Lutaud, in *Journal de Méd. de Paris,* recommends the following for constipation in women:

R.	Res. podophylli	gr. xxv	1	66
	Euonymin	gr. v		33
	Ext. belladonnæ	gr. x		66
	Ext. hamamelidis	gr. xx	1	33
	Saponis	gr. xxx	2	

M. et ft. pillulæ No. 50. Sig. Take one or two pills after the evening meal.

—*Ther. Gazette.*

Glycerin in Fever Mixture.

The *Clinica Moderna* recommends the following mixture as beneficial in allaying thirst and fever:

℞.	Glycerini puri	ʒviiss	30	
	Acidi citrici	ʒss	2	
	Aquæ destil., q. s. ad	ʒxxv	100	

M. Sig. One to two tablespoonfuls at one dose to allay thirst and fever.

Chronic Eczema of the Hands.

℞.	Iodi	gr. iss		1
	Potassii iodidi	gr. iv		25
	Glycerini	ʒiii	12	

M. Sig. Apply the paint to the hands every evening and then envelop them in lint.

Edelfsen, in *New Eng. Med. Monthly,* states that he has adopted this treatment with success where other remedies have failed. The irritation is always relieved and a cure effected in about two weeks. In more obstinate cases he uses a boric-acid ointment applied in the morning and the above combination in the evening.

—*Am. Jour. Surg. and Gyn.*

Nutrient Enema.

The *Medical Sentinel,* in commenting on treatment of ulcer of stomach, states that the best treatment consists of complete rest in bed, no food by the mouth, and that the nourishment should be given entirely by the rectum. The enemata should be administered four hours apart, first cleansing the bowel with an enema of warm water by means of a high injection. The following formula is recommended by J. B. Herrick:

℞.	Somatose	ʒi	4
	Egg—one-half		
	Sodii chloridi—small amount		
	Spts, frumenti	ʒi	4

M. Sig. At one feeding per rectum.

Medicolegal.

Insane Person's Estate Liable for Necessaries.—The Court of Appeals of Kansas holds, in Palmer vs. Hudson River State Hospital, that, to charge the estate of an insane person with the expense of maintenance and for necessaries furnished, it is not requisite that there be an express promise to pay therefor, either by the insane person or guardian. In other words, it holds that the estate of an insane person is liable for necessaries furnished him upon an implied contract. Nor does it consider that any statute is necessary to create a liability on his part, binding his estate, for such benefits received by him. Besides this, it holds that where an insane married woman was a citizen of Kansas, where her husband and children were domiciled, who were able to support her, as it was their duty to do, and she went on a visit to relatives in New York, where she was admitted to a hospital as an indigent insane person, it was the duty of the agents of the hospital, on discovering that they had been providing an asylum for a person not entitled thereto as a lawful right, and that the recipient was able to refund to the state its expense therein, to sue, in the name of the hospital, to recover it.

Not Authorized to Burn Buildings for Smallpox.—In Prichard vs. Commissioners of Morganton, brought to recover for the burning of a dwelling as a health precaution, the Supreme Court of North Carolina holds that the board of commissioners of the county, as representing officially the county, were not liable, for the reason that there was no statute making them so, either expressly or by necessary implication. And the town commissioners, as representing the town community, it holds, were not liable: first, because the act complained of was for the interest of the state at large; and, second, because they unreasonably exceeded the powers conferred on them. True, the town charter authorized them to take such measures as they might deem effectual to prevent the entrance into the town, or the spread therein, of any contagious or infectious diseases; and under these powers they were permitted to cause to be destroyed or disinfected such furniture or other articles as should be believed to be tainted or infected with any contagious or infectious diseases, or which there should be reasonable cause to apprehend would generate or propagate diseases, and might take all other reasonable steps to preserve the public health, and for this purpose might use any money in the treasury. But, as the court construes it, that was no authority to burn or destroy any house or residence. Neither does it see the necessary authority in a statute providing that in cases where the county superintendent of health declared that a nuisance existed, it should be removed or abated at the expense of the town, city, or county, in case of the offender's inability to remove it, though the expense should not exceed $100, particularly when the superintendent had not acted in the matter. Nor does it see authority to burn a dwelling in a statute conferring on boards of county commissioners power to make rules, regulations and by-laws for preventing the spread of contagious and infectious diseases.

A proper disinfection, it thinks, would be the extent of their powers in respect to property thus tainted or infected.

Must Take What Charitable Hospitals Have to Give.—The United States Circuit Court lays down the rule, in the case of Powers vs. the Massachusetts Homeopathic Hospital, that a beneficiary of a charitable corporation, as for example a patient in a hospital which is chartered or must be legally classed as a charitable institution, must take its bounty for what it is worth. In other words, it holds that no person who accepts the bounty of any charity, can maintain a suit on account of the method of the administration of the bounty which is accepted. It declares it absolutely inconsistent with the underlying idea of charities as recognized by the law, to hold that the same rule that applies to a person or institution employed for compensation to do a certain service applies to the distribution of charity. In its view, the person who enters a charitable hospital is not a contractor; neither is the hospital a contractor with that person. The person who enters is a mere licensee, like a guest who enters one's house, and who must take the service as he finds it. Assume that a stranger enters one's house, and is suddenly taken with a severe sickness. Can such householder, it is asked, be held responsible for the selection of an incompetent surgeon or physician, or for neglect on the part of a servant, with reference to the care of that person? He can not, it is answered, have higher rights than a member of the household of which he has for the time being become, as it were, a part. All he is entitled to is not to be led into a danger known to his host, and not known or reasonably apparent to himself. That, the court holds, is the precise rule that applies to a public charity. And, in this respect, it holds, private charity and public charity rest on exactly the same ground, and there is no basis in either case to hold that the person who receives bounty is a contractor, a person contracting for service, as one engages service when he ordinarily employs a surgeon. He is, in law, only a licensee. Nor does the court consider that the reception—the frequent reception—of money from patients changes the nature of the institution; and the following out of this proposition it says necessarily leads to the conclusion that the reception of money from any particular patient does not change the nature of the service rendered that patient, so far as anything said here is concerned. It looks at the money paid in such a case as a proper contribution to a charity on the part of the person who makes the payment and receives the benefit of the charity. It is not compensation in the sense of the law. Furthermore, the court holds that the officers of a charitable corporation have no power by contract to impose any liability beyond that which the law raises. If it is unsuitably or carelessly managed, the remedy is in the hands of the state. So, for the reasons adduced, it holds the hospital here sued not liable for an injury alleged to have occurred to a patient through the neglect of a nurse, even if it was a "pay" patient, it being, in law, a charitable corporation.

Injured Person's Duty to Employ Physician.—Texas & Pacific Railway Company vs. White is the title, in the United States Circuit Court of Appeals, Fifth circuit, of an action that was instituted by the latter party to recover damages for personal injuries alleged to have been sustained by him while a passenger on this company's railroad, through the negligence of its servants. He averred that he received a serious injury in the abdomen, resulting in causing him great pain and in producing a serious and painful disease of his bowels and sharp, severe and continuing pain in his spine or back, and in producing varicocele. But, for reasons which he afterward endeavored to satisfactorily explain, he did not at any time mention the fact of his having been hurt to any of the servants of the company. Besides, he proceeded on his journey with his car of cattle, which he was accompanying, riding on the top of that car part of the way, and even assisted in driving the cattle from the railroad to the ranch, traveling on foot a distance of thirty-seven miles, after which he did more walking, and some railway traveling. Nor did he, during the ten days thus consumed, before he reached home, employ a physician, his explanation thereof being that he had hopes of wearing it out, and that it would pass off, and that he wanted to get back home where he could get his family physician. It should, perhaps, be added that a man who was on the train at the time of the alleged accident testified that the party claiming injury spoke to him about it, and showed him a bruised place on his side. On the trial, the judge who presided recognized the settled doctrine that it was the plaintiff's duty to use reasonable care not to aggravate, or suffer to be aggravated, so far as he could prevent it, the injury which he had received. Continuing, the court of appeals says that the application of this doctrine to the subject of the plaintiff's failure to promptly obtain professional medical and surgical assistance is not very clearly shown by the adjudged cases or text-writers, so far as it has been able to examine. Here the injured party believed that the exigency of his business required him to continue his journey with his cattle, and to continue his care of them until they reached the ranch, and, the court says, it was not unnatural or unreasonable that he should hesitate to employ physicians who were strangers to him while he could endure the suffering he experienced until he could reach home, to have the advice and attention of his family physician. It goes on to state, however, that, while these reasons for his action commended themselves to its experience and sympathy, yet if therefrom an aggravation of his injury resulted, from his active attention to his business or from his failure to obtain the advice and aid of competent physicians who were accessible, such aggravation, whether it resulted from his active exertion, or from his neglect or failure to obtain the needed medical or surgical assistance, could not, in justice, be charged against the railway company in addition to its liability for the original injury to the extent of the damage it necessarily caused. And it holds that it was as incumbent on him to procure the advice of a competent physician and surgeon, if accessible, as it was to refrain from such physical exertion as tended to aggravate his injury. There being proof tending to show that a part of the trouble could have been speedily cured, at a small expense and without hazard, by prompt proper surgical treatment, it holds that it was for the jury to say whether the conditions required a surgical operation, as also to determine the issues of fact raised by conflicting evidence as to the existence, nature, extent and likelihood of relieving the other troubles. Then, it says that, from the nature of the case, opinion testimony must be relied on, but in considering opinion or expert testimony the opinion of the jury is the chief factor in reaching ultimate conclusions.

Societies.

Coming Meetings.

Wyoming State Medical Society, Cheyenne, Oct. 9-10.
Mississippi Valley Medical Association, Asheville, N. C., Oct. 9-11.
Iowa State Association of Railway Surgeons, Des Moines, Oct. 11-12.
Vermont State Medical Society, Rutland, Oct. 11-12.
Tri-State Medical Society of Alabama, Georgia and Tennessee, Chattanooga, Tenn., Oct. 11-13.
New York State Medical Association, New York City, Oct. 16-18.
American Public Health Association, Indianapolis, Ind., Oct. 22-26.
Medical Society of Virginia, Charlottesville, Oct. 23.
Southern Surgical and Gynecological Association, Atlanta, Ga., Nov. 13-15.
Oklahoma Territory Medical Society, Oklahoma City, Nov. 15.
The Tri-State Medical Association of Mississippi, Arkansas and Tennessee, Memphis, Nov. 13-15.

THE JACKSONVILLE (Ill.) MEDICAL SOCIETY held a meeting September 15, at which Dr. Frank P. Norbury read a paper on "The Progress of Therapeutics."

THE TRI-STATE MEDICAL SOCIETY OF ALABAMA, GEORGIA AND TENNESSEE will hold its twelfth annual meeting in Chattanooga, Tenn., October 11, 12 and 13, immediately after the close of the Asheville meeting of the Mississippi Valley Medical Society. A rate of one fare or one and one-third fares, on the certificate plan, has been made for the meeting.

The San Jose (Cal.) Medical Association met on September 20, when Dr. James R. Curnow presented a paper on "Epilepsy," which was followed by a spirited discussion.

The Skagit County (Wash.) Medical Society effected a temporary organization September 13, at Burlington, with the following officers: Dr. M. B. Mattice, Sedro-Woolley, chairman, and Dr. Charles C. Harbaugh, Sedro-Woolley, secretary.

The Vanderburgh Medical Society met at Evansville, Ind., September 18, and listened to a paper by Dr. Jacob H. Keith, in which he discussed the food-supply of Evansville, commending the meats, but condemning much of the milk.

The Hartford (Conn.) Medical Society held its first fall session September 16, Dr. John F. Dowling in the chair. Dr. Arthur J. Wolff exhibited the new substance, "urein" (described in The Journal, xxxv, p. 711). Dr. Joseph E. Root presented a specimen of tumor and Drs. Michael A. Bailey and M. M. Johnson made reports as delegates to The American Medical Association.

The Lycoming County (Pa.) Medical Society met at the Williamsport Hospital, September 14. Dr. E. Roy Gustin, Williamsport, read a paper on "Skin Diseases"; Dr. Charles M. Heberton, Hughesville, spoke on "Poisons"; Drs. John A. Klump, Williamsport, and Joseph W. Albright, Muncy, discussed "The Treatment of Shock," and Dr. Charles E. Thomson, Scranton, considered "The Treatment of Congenital Club-Foot."

The Delaware County (Pa.) Medical Society held its regular meeting September 13 at Chester, Dr. H. Gallagher, Glenolden, in the chair. Dr. Robert S. Maison, Chester, spoke at length of the epidemic of typhoid fever at Trainer. He considered the epidemic due solely to milk from one dairy, the proprietor of which was himself ill with the disease. Drs. Samuel D. Risley, Media, and Samuel Trimble, Lima, reported cases, and Dr. William B. Ulrich, Chester, gave a description of Galveston Island.

The Santa Fe Railway Medical and Surgical Society held a special meeting in Colorado Springs, Colo., September 26. Papers were read by Dr. Charles G. Elliott, Blackwell, Okla., on "The Modified Form of Smallpox"; Dr. Luther D. Jacobs, Emporia, Kan., on "Infusion of Normal Saline Solution in Shock Without the Accompaniment of Hemorrhage"; Dr. J. Frank Connell, Las Cruces, N. M., on "Canodol as a Detergent in Surgery"; Dr. E. B. Shaw, Las Vegas, N. M., on "Typhoid Fever and Its Treatment," and Dr. George R. Highsmith, Carrollton, Mo., on "Trauma an Etiologic Factor in Tuberculosis of Bones and Joints."

The Central Wisconsin Medical Society held its quarterly meeting at Janesville, September 12, with an attendance of about one hundred, President Dr. John M. Evans, Evansville, in the chair. Papers were read by Dr. Lewis F. Bennett, Beloit, on "Fractures of the Condyles of the Humerus"; Dr. William E. Dold, Lake Geneva, on "Suggestions for the General Practitioner Concerning Certain Forms of Insanity"; Dr. John E. Allaben, Rockford, Ill., on "Treatment of Inoperable Sarcomas With Mixed Toxins of Erysipelas and Bacillus Prodigiosus"; Dr. Lawrence H. Prince, Palmyra, on "Anesthetics"; Dr. Samuel Moyer, Monroe, on "Appendicitis and the Country Doctor"; Dr. Thomas W. Nuzum, Brodhead, on the converse "The Country Doctor and Appendicitis," and Dr. Arthur C. Helm, Beloit, on "Who Shall Operate." Dr. John F. Pember, Janesville, reported a case of pyonephrosis. At the banquet, held between the sessions, Dr. James Mills, Janesville, was toastmaster.

The Detroit Medical and Library Association held a regular meeting September 17, at which Dr. Henry R. Varney read a paper entitled "Treatment of Lupus." Excision has been used with good results, but is objectionable when the lesions are on the face. The most satisfactory treatment is curettage. With the common dermal curette one is able to distinguish, with but little experience, the healthy tissue from the broken-down, cheesy degeneration of the tubercle. Freezing mixtures should not be employed. Linear scarification is slow and objectionable. Electrolysis as advocated by Dr. Jackson is satisfactory, the effect of the electricity on the tubercle nodule is two-fold, the heat destroys the germs and the electricity stimulates cell change. Mechanical measures consist of caustics and caustic pastes. Nitrate of silver stands first as a caustic. It penetrates and destroys the isolated tubercle, but spares healthy tissue. Arsenical pastes act more quickly than silver nitrate, but are more painful and can be applied only to small areas. The stronger acids, with the exception of pyrogallic acid, are objectionable, as they destroy all tissues. A comparatively new treatment for lupus is the X-ray exposure. Dr. W. A. Pusey, Chicago, discovered that a number of exposures would blanch the hair, stimulate nutrition of chronic indurated lesions, reduce inflammation and destroy the hair bulb. On these observations the treatment of chronic skin affections is based. Treatment is painless, the exposures are short in duration, the area can be controlled and there is no scarring, but its antiseptic power is as yet unsettled.

Medical Society of the Missouri Valley.

Annual Meeting, Council Bluffs, Ia., September 20, 1900.

GOAT'S LYMPH.

Dr. T. L. Putnam read a paper on this subject. He described its preparation, composition and uses, and spoke of its use in his hands.

The discussion was most extraordinary. Dr. Macrae thought that Dr. Putnam had been deceived. The lymph was a good thing to quack with, but it was by no means new, Dr. Brown-Séquard having brought it out years ago. It had been used by thousands of French, German and American physicians, who had found such lymph utterly useless; and it had been again introduced by an insignificant Missouri doctor, exploited by a company organized by a Chicago doctor in the most mercenary manner, of which he personally knew, because they had tried to work him for $30 a month for the good-will of the thing.

Dr. C. B. Wallace, St. Joseph, felt that it was very unfortunate that such a paper had been read, that it came originally from the degenerate mind of Brown-Séquard.

Dr. B. B. Davis was sorry the paper had been read. The society could not go on record as encouraging such a preparation, and protested against it.

CONTUSION OF THE BRAIN.

Dr. J. Cameron Anderson read this paper. It was a plea for more careful study of cases of contusion, pure and simple, without fracture. He related the symptoms in detail and cited two interesting cases. The first was completely unconscious for four days, and partially so for two more. The second was totally unconscious for eight days, and partially so for sixteen more. Somewhat later there was great improvement in the mentality, which soon became clear, but without memory of recent past events. He had received the best results in treatment from the use of cathartics, then laxatives, medicines which were vasomotor dilators, and liquid diet; also from the use of the iodids.

Dr. B. B. Davis was of the opinion that cases of concussion are rare, those of contusion frequent; the injuries from concussion are usually minor, those from contusion are often serious, delayed and their general results permanent. The prognosis should be very guarded.

Dr. C. C. Allison felt that cases of pure contusion gave a very narrow field clinically; uncomplicated cases were very rare. Hemorrhage and fracture were much more often seen. Contusion affected the blood-vessels, because they were not well supported; small extravasations were present; often a laceration, which added to the shock.

Dr. Anderson, in closing, said that in contusion there was always a laceration of the vessels; the medulla was greatly damaged. The character of the heart's action and the respiration showed the damage. Many cases supposed to be fractures were not, and the trephine proved it.

CANCER OF THE UTERUS.

Dr. B. B. Davis made a strong plea for the education of the women of the country to the necessity of a knowledge of their condition after child-birth, as to laceration of the cervix, etc. They should be taught the danger of leucorrhea, erosions, lacerations, irregular hemorrhages, and especially when occurring between 40 and 50. While most tears heal, they are too often a source of irritation and tend to malignancy. Nulliparous women often suffer from erosions, and these need care as well as the multipara. Cancer is always local at first, and early clean removal entirely eradicates it. No recurrence takes place. Early knowledge is imperative. Physicians are seriously to blame when they do not insist on an examination, and when they make light of the symptoms present.

Dr. M. F. Weymann urged greater care on the part of physicians in the preparation of specimens to be sent to the microscopist.

Dr. Daniel Morton said that he never failed to investigate all cases of irregular hemorrhage, and especially in women between 40 and 50 years of age. He felt that the profession was much to blame for neglect in this matter. He was very careful to treat in the most thoughtful manner those patients doomed to death because too late for operation.

Dr. C. B. Wallace made a strong plea for all practitioners to make more careful examinations.

Dr. J. M. Knott said that he had been repairing cervices for many years and had been on the watch for early cases of cancer, but had never seen one; he had had the misfortune to always see them when inoperable. Not one of his cases that were operated on had ever developed cancer to his knowledge.

STAB WOUNDS OF THE LIVER.

Dr. Daniel Morton, St. Joseph, reported a case of a man who had been stabbed over the liver. The external wound had been sewed up and patient sent home. Grave symptoms coming on, he sent to Dr. Morton, who opened up the wound. At this time shock was profound, jactitation present, heart feeble and internal bleeding certainly indicated by the conditions. On cutting the sutures the bleeding was profuse and welled up from beneath the liver. The wound was felt under the lower surface of the liver; five yards of 2-inch iodoform gauze were crowded beneath the liver and the hemorrhage ceased. A gallon of clots was removed; coffee and salines were freely used. In twenty-four hours the man was out of danger; the gauze was removed, a yard at a time each day after the third, and recovery took place. He was much impressed with the value of hypodermoclysis in such cases.

CONTUSIONS OF THE EYE WITH HEMORRHAGE INTO AQUEOUS.

Dr. M. F. Weymann made a report on four cases of trauma, two being from a stick striking the eye and one from a ball ricochetting and striking the eye. In these cases glaucoma and iritis were almost certain. In some of them the lens was dislocated. As regards the treatment, drawing off the blood is not practical; atropin is demanded. Glaucoma is best relieved by the knife and hot compresses are very useful. The prognosis should be very guarded until the clot disappears, as synechiæ, iridocyclitis and cataract are often produced.

MARCY-BASSINI OPERATION FOR INGUINAL HERNIA.

Dr. C. B. Wallace said the restoration of the normal obliquity of the inguinal canal was taught by Marcy, of Boston, long before it was by Bassini, and yet the operation is commonly known as the Bassini operation. He felt that Marcy's name should be associated with Bassini's in the name of the operation. This restoration, the isolation of the sac and the suture of the transversalis and internal oblique to Poupart's ligament are universally followed. He is strongly in favor of isolation of the sac by dissection from its neck to its extremity, rather than the reverse, as is often done.

Dr. B. B. Davis expressed himself as happy in the thought that herniotomy was not a destructive operation, but one in which the patient's condition was radically improved as regards comfort and great danger prevented. He now used the original Bassini method more than formerly. He never saved the sac, as done by Macewen and Kocher, but ligates and cuts it off. For a long time he used the Marcy tendon, but now uses the chromicised catgut. He thinks that surgeons tie the sutures too tightly sometimes; if the tension is too great he ties loosely and uses more sutures. In his experience patients who have the injection treatment have adherent omentum. He dresses children with cotton and iodoform-collodion, not reinforced. He condemns the Halsted method.

Dr. Morton feels less and less sure of his results with the Bassini method, has had some recurrences, and uses silk-worm gut for suture.

SARCOMA OF THE KIDNEY.

Dr. Arnold Jolly said it was the most frequent tumor seen, often congenital and rapid in its course. The symptoms are swelling, hematuria in about one-half of the cases, pain in about one-fourth the cases, with jaundice and nervous condition.

Dr. Jonas said that a few words could cover all that was needed to be said. All reports are discouraging; shock of operation is very great; especially if the operation is done on the left kidney death is certain.

CASE OF DOUBLE URETER.

Dr. J. E. Summers, Jr., Omaha, said the condition is rare. It may be found on both sides or on but one, usually on the left. Two pelves, not connected, are usually found; the ureters may join or may enter the bladder separately. He has seen one double case, each of the four ureters entering the bladder separately. His own case was one of double ureter on the left side. Patient was a girl of 2½ years. The child had been troubled for a long period with irritability of the bladder, and had wet the bed at night. Tubercle bacilli were found in the urine. On laying bare the left kidney a most puzzling condition was found. A tube, soft, collapsible, almost as large as an intestine, was seen; examination showed it to be a ureter of tuberculous character. Further examination showed the other ureter, normal in size; there were two pelves. The kidney was plainly tuberculous. He removed the kidney, cutting off the enlarged ureter close down to the pelvic brim, and the other near the kidney. The ureters entered the bladder separately. Recovery from the operation was uneventful; irritability of the bladder persisted, however, and fewer bacilli were found as the child recovered. Urotropin and methyl blue were found very useful for the irritability. He desired to impress the society with the importance of the necessity of proving the presence and condition of the supposed sound kidney in all cases requiring a nephrectomy. He makes a button-hole incision and palpates the kidney.

THE MASTOID SEASON OF 1900.

Dr. Harold Gifford stated that the season of 1900 has been more productive of mastoid troubles than he had ever seen before. Those patients who begin with simple middle-ear trouble do not reach the specialist until late spring or early summer. He related the case of a physician who developed ear trouble. Instead of coming and undergoing treatment, he kept on with his hard country work, driving many miles daily, for a month. Dr. Gifford operated on both mastoids; pus was found, and he seemed better, but relapsed. Two days later he was operated on again. No communication was made with the subdural space. Aphasia followed, and later delirium. The conditions seemed to point to a cerebral abscess in his judgment and that of two surgical consultants. He opened again over the temporo-sphenoidal, but no pus was found. Death took place the next day. The autopsy showed no abscess anywhere, no pus between dura and skull, nor exudate. It was a serous meningitis, infection passing through the superior and posterior mastoid cells. He has reached the conclusion that many mastoid cases present neither tenderness nor swelling over the mastoid, and yet mastoid disease is present. He makes it a rule that, with or without the ordinary symptoms of mastoid disease, if no improvement takes place in two weeks, to operate. He regards the presence of discharge and sleeplessness alone as showing the necessity for operation.

Dr. Stone related the history of a patient [illegible] ho
double mastoid disease; she was under [illegible]
and Dr. Gifford in consultation for three [illegible]
observation could discover no symptom

when operation was done. Pus was found on both sides, although the patient had talked apparently clearly up to the day of operation.

Dr. Weymann felt that mastoid pain, tenderness and confusion of intellect were sufficient grounds for operation.

Dr. Lord thought that the leucocyte count gave the best possible guide for operation. In mastoid cases requiring operation it ran from very low to very high.

THE TREATMENT OF FEVER IN INFANTS.

Dr. H. M. McClanahan read this interesting and useful paper, which was a plea for greater care and less medicine in the treatment of such a condition. Many are much overtreated. The degree of fever alone is not to be considered, as its continuance is of greater importance. He advises against the new remedies designed to reduce fever, and much prefers the old ones; he uses cold and thinks the method of prime importance. He avoids scaring the children by having them placed on the mother's lap on a rubber sheet. He irrigates the intestinal canal through a No. 8 or 10 catheter, with the fountain syringe about 4 feet high; uses warm water first, then cool, then cold, and gets a half-pint of the cold in the bowel and leaves it there. He also uses the wet pack, first warm, then cool, then cold, and rubs the body while wet. In convulsions use cold to the head and heat to the feet. Food is often withdrawn for hours; it sometimes acts as an irritant. He seldom uses drugs; phenacetin is his favorite when one is needed—one grain an hour. He gives chloral in the rectum—½ grain for a child of 6 months, a very valuable remedy when there is great restlessness. When the urine is high-colored and very acid he finds that the citrate of potash is most valuable, and uses large doses well diluted.

The Society voted to send $25 to the Rush Monument Fund.

The following officers were elected: President, Dr. V. L. Treynor, Council Bluffs; first vice-president, Dr. B. B. Davis, Omaha; second vice-president, Dr. F. E. Sampson, Creston; treasurer, Dr. T. B. Lacey, Council Bluffs; secretary, Dr. Charles Wood Fassett, St. Joseph.

Next meeting in March, 1901, at Omaha.

American Association of Obstetricians and Gynecologists.

Thirteenth Annual Meeting, Louisville, Ky.

Sept. 18-20, 1900.

(Concluded from page 842.)

Dr. Rufus B. Hall, Cincinnati, in the chair.

FIBROMA OF THE OVARY.

Dr. L. H. Laidley, St. Louis, Mo., contributed this paper. After giving the pathology of fibromata of this organ, the author reported the following case: Mrs. H., aged 29, married, usually enjoyed good health, with the exception of almost complete deafness due to a specific disease, for which she was treated some fifteen years ago. She became pregnant and was delivered of a healthy child about two months before the removal of the tumor. She had noticed a tumor in the region of the left ovary about two years ago, hard and slightly movable, which continued to grow to the size of two fists. In the development of pregnancy it was pressed upward on a line with the umbilicus and could readily be felt in her left side. There was no pain nor discomfort with its presence up to the tenth day after her delivery. She had a favorable "getting-up," when, on the fifteenth day, she had fever, with pains, causing her to again take to her bed. These continued until he saw her, two months later. There could be readily felt and seen a hard, immovable tumor in the left umbilical region, with considerable ascitic fluid in the cavity. On January 20, an abdominal section was made, revealing a solid tumor adherent to the anterior wall of the abdomen, which was detached. Posteriorly the folds of the bowel were adherent to that portion, which were also dissected off, the tumor freed, kidney-shaped, hard, with short pedicle, one inch in diameter by two inches in length, which was ligated and the tumor removed. In tying the ligature it readily cut through its peritoneal covering, but secured the stump from hemorrhage. On examining the remaining organs, the stump of the pedicle occupied the location of the ovary; the tube remained distinct and separate from the tumor; the opposite side showed a healthy tube and ovary; there was considerable hemorrhage from the surface, bleeding following the operation, but with that exception there was no difficulty encountered. The patient made an uninterrupted recovery. The tumor weighed 32 ounces and measured 6x5x3 inches. A histological report accompanied the recital of the case.

Dr. Laidley also reported a case of "Hernia or Diverticulum of the Chorion."

DIFFUSE NON-MALIGNANT PAPILLOMA OF THE VULVA.

Dr. Edward J. Ill, Newark, N. J., read this paper and showed a specimen which he removed from a patient aged 68. The growth had been of over three years' standing. The inner surfaces of the vulva were thickened, at some places appearing horn-like, white and smooth; at other places there were heavy papillæ, which rose considerably above the surrounding tissue and were from 3 mm. to 15 mm. in diameter at their base. The disease extended from the beginning of the vulva above down to the posterior commissure. It covered the whole vestibule except the tissue immediately surrounding the external meatus of the urethra, and was well defined, but stopped at the vaginal mucous membrane. The vulva as a whole stood out far beyond its normal elevation. The whole vulva was excised. The structure of the tumor corresponds with that usually found in papillomata of the skin. A second case was spoken of by the writer.

THE EDUCATION OF THE LAITY ON SEXUAL MATTERS; WHEN SHALL THEY BE TAUGHT, AND TO WHAT EXTENT?

Dr. Rufus B. Hall chose this for his Presidential Address. The family physician should be the educator of the people in sexual matters, and when he gets the endorsement, and is sustained in his position by the specialist, his influence will be greatly strengthened and widened. He advises that during the last year in high school, in every school in the land, a textbook be employed embracing embryology, hygiene, anatomy and physiology, including sexual physiology, and that these subjects be taught to every student, both male and female. He believes that this could be accomplished without shocking the morals of the most fastidious individual by dividing the classes so as to separate the sexes. A female teacher should instruct the girls and a male teacher the boys. This is the very time in life when individuals should be taught to know the functions with which Providence has endowed them, and how to care for their bodies as well as their minds. It would be a revelation to them to know that the sexual organs in animals as well as the human race are among the first centers to be formed, and can be recognized as such early in intrauterine life. When the laity become educated on this subject as they should be and understand the meaning of pelvic inflammation in young wives as gynecologists understand it, the parents and guardians of young girls will realize that they owe them a duty before consenting to their marriage.

PRIVATE HOSPITALS AND THEIR MANAGEMENT.

Dr. Joseph Price, Philadelphia, said that the well-organized private hospital, managed by such distinguished men as Marion Sims, T. G. Thomas, Thomas Addis Emmet, William Goodell, Stone, of New Orleans, and a few institutions of the present time doing the best work, offer advantages that are not given by the schools or the political hospitals. The political hospital is not the only corrupt institution; a few of the well-endowed general hospitals, managed and handed down in families to the third, fourth and even the fifth generations, are the most dangerous institutions in the medical profession. It is always a misfortune to an endowed charity or public hospital for a family to be in full possession of the funds or endowments, in that it results in impairing or destroying its usefulness. No one has ever, to the speaker's personal knowledge, made money and accumulated wealth out of a private sanatorium. He may out of the fees, but never out of the board, care and nursing of patients. The board of patients rarely pays 5 per cent. on the money invested. A good number of these institutions have been financial failures and have closed. Private hospitals give the operator the best opportunity for doing good work. In well-managed private institutions the patient has one or more attendants with well-regulated relays. In public institutions the speaker rarely finds a nurse in large wards, the only attendants about the patients being a convalescent patient or an old pelican of an attendant. Professional care, one or many visits daily, favor a speedy convalescence. The early and late assurance that a patient is doing nicely does a world of good. Fresh beds, and the numerous little attentions from young, intelligent nurses favor comfort and confidence. It is surprising how much more cheerful patients are in private hospitals than in general, public or school institutions. The surroundings of general hospitals are generally depressing. Patients are eager or impatient to get home prematurely. In a well-managed private institution they are easily controlled and are willing to remain until they are fully convalescent. Hurrying patients out of general hospitals, one, two or three weeks after serious operations results in accidents and complications, post-operative sequelæ, difficult to correct. In private institutions there is added a well-directed rest-cure treatment, which gives pleasing results.

POSTRECTAL OR PRESACRAL GROWTHS.

Dr. James F. W. Ross, Toronto, presented this paper, in which he reported four cases of postrectal tumors, excepting the osteomata. He discussed benign and malignant growths in this region; also their etiology, symptomatology and diagnosis and prognosis, and treatment. No novice should undertake the removal of a postrectal growth. It can only be done by one who has become familiar with pelvic surgery, and who is fully master of the situation. The operator must be full of resource and should be rapid in his movements. In making his incision into the abdominal wall he should always remember that it should be made high up and enlarged downward after the position of the bladder has been ascertained. The author has had no experience with the removal of such postrectal growths by enucleation from above. He is well aware that many thoughtful, prudent and daring surgeons do not hesitate to close the abdomen when this condition is met with. What should the technique of such an operation be? Should the mesorectum be incised close to or far away from the bowel? Should not the incision always be parallel to the vessels and not across them? How is the surgeon to accurately determine the situation of the ureter and, when discovered, how can he avoid it? How can he best guard against injury to the large vessels? In dealing with branchial cysts in the neck the speaker has followed them almost to the spine, but has then left the deep portion of the cyst wall, if it could be called a wall. It seems to him that he would have been forced to deal with the last case he reported of presacral cyst in exactly the same manner because the periosteum and so-called cyst wall were so intimately connected. It would not be wise to drain such a cavity into the peritoneal cavity, but would be more prudent to attack such cysts through the postanal tissues, perhaps with the removal of the coccyx. The solid tumors should always be attacked from the front.

THE LIGATURE AND THE VALUE OF DRY STERILIZED CATGUT.

Dr. J. Henry Carstens, Detroit, described a modification of the Boeckmann method of preparing catgut. The ligatures are prepared in the following manner: Catgut is put in ether for a few days, or a week, until the fat is all removed, and then cut in strips 18 or 20 inches long. Three of these are wrapped in fine tissue paper, then placed in a small envelope. The latter is closed and placed in a Boeckmann sterilizer and subjected to dry heat for three hours. A thermometer is kept in the apparatus, so that the heat is at least 300 F. At the expiration of that time the heat is shut off and the ligatures remain in the sterilizer without disturbance for twelve to eighteen hours, which gives any spores that may be present an opportunity to develop. The heat is again used, and the ligatures are again subjected to 300 F. They are now sterile. They are put in an envelope and can be carried that way in a satchel. When ready for use the end of the envelope can be torn off and the ligature, with the tissue paper, dropped into alcohol, the tissue paper removed and the ligature can be threaded and used. These ligatures are not slippery or greasy, as is the catgut prepared with different oils. The following points were emphasized: All buried sutures ought to be absorbable, and absolutely sterile. Chemicalized sutures are no more sterile than plain sutures. A chemicalized suture is harder and remains longer in the tissues. This latter is a disadvantage. If in a special case it is desirable that a suture should remain longer, dry sterilized kangaroo tendon can be used.

Dr. Frank F. Simpson, Pittsburg, Pa., read a paper on "Some Contraindications to the Intraperitoneal Use of Normal Salt Solution After Abdominal Section."

SIMPLE METHODS IN PELVIC SURGERY.

Dr. John B. Deaver, Philadelphia, said that simplicity is the sine qua non of good surgery. It means safety, surety, confidence, neatness and a great saving of time, which is an essential factor in the success of many operations. The abdominal route is by far the more rational and therefore the best method of operating on the pelvic organs in the majority of cases, and offers several advantages that render it preferable to the vaginal. Radical operations per vaginam are, with few exceptions, the author thinks, to be discountenanced for several good and sound reasons: 1. The limited area for manipulation. 2. The impossibility of inspection without destruction and removal of the uterus, which should not be removed except for good and sufficient disease of that organ itself. 3. The marked increased liability to hemorrhage, both primary and secondary. 4. Increased danger of injuring ureters, bowel, bladder and large blood-vessels. 5. Danger of doing incomplete surgery. 6. Inability to repair satisfactorily injuries to bowel or bladder, etc. 7. Inability to deal safely with an inflammatory mass which involves the vermiform appendix.

THE TREATMENT OF FIBROIDS IN THE NON-PREGNANT UTERUS.

Dr. E. F. Fish, Milwaukee, Wis., discussed the advisability of operating in all cases of fibroids of the uterus as soon as discovered, and leaves it an open question. He emphasizes the necessity of radical interference whenever the tumor or tumors are productive of pain, hemorrhage, pressure, constitutional impairment, unless there be existing disease, such as nephritis, diabetes, tuberculosis, etc. Of radical treatment, he thinks that myomectomy is the operation of choice, whether subserous, interstitial or subcutaneous, if it is single and can be enucleated without loss of tissue and the cavity closed and covered with peritoneum. Where several tumors exist the judgment of the operator comes into play. Many nodules mean many foci, and the author opposes myomectomy on the ground that some of these may not be discovered and later develop and demand another operation. He thinks, too, that under such circumstances the condition might, and likely would, call for future operation. The vaginal route is favored for small tumors, the abdominal for large ones. Hysterectomy is favored when the tumor involved so much uterine tissue that a proper closing of the tumor cavity is not possible, when the organ is studded with small tumors or nodes, when coexisting pelvic disease is present, when the growth is degenerating, when there are adhesions, when the tubes and ovaries are involved to such an extent that they must be sacrificed, when the disease is no longer local, when the change of life has occurred. He favors supravaginal amputation, leaving the cervix when sound, and panhysterectomy when the cervix is lacerated or diseased. He leaves the ovaries if sound, or if only one is sound he leaves that, or if only part of one, he leaves the healthy part. He believes in ignipuncture for small pea-like cysts, and leaves ovary. He is convinced that it modifies the nervous symptoms which usually follow complete removal.

ACUTE SENILE ENDOMETRITIS.

Dr. L. H. Dunning, Indi[illegible] d [illegible] with [illegible] title, it being the second wri[illegible] ct, ..

which he reaffirms his belief that it is a distinct lesion that has not heretofore been adequately described. Since his previous paper he has encountered three more cases, two of which were attended by sanguineo-purulent discharges from the uterus, and one in which there was a large pelvic abscess. The inflammation tends to spread beyond the endometrium into the Fallopian tubes, ovaries and pelvic peritoneum, resulting in much suffering and ill-health, and not infrequently leading to so serious involvement of these structures as to demand operative procedures, such as extirpation of the uterus and appendages, or vaginal incision and drainage of a pelvic abscess. The chief cause of the lesion is infection. It is not definitely self-limited, but tends to become chronic and to lead to marked degenerative changes within the uterus. The treatment recommended is, in cases where the appendages are not involved, dilatation, curettage, the application of a mild caustic and prolonged drainage. When the uterine appendages are involved in the inflammatory process, extirpation of the uterus and appendages is advocated.

TUBO-OVARIAN ABSCESS AND HOW TO DEAL WITH IT.

Dr. Edwin Ricketts, Cincinnati, Ohio, said that tubo-ovarian abscess is frequently caused by the proximity of the ovary to an infected Fallopian tube. The disease may be complicated by normal or ectopic pregnancy, intestinal, vaginal or vesicle fistulæ, and by appendicitis. In the dormant stage the author operates by the abdominal route; in the acute stage he explores by the abdominal route, and then decides between completing the operation in one or two sittings. Following abortion or delivery at full term, vaginal drainage, in his opinion, often puts the patient in better shape for an abdominal section later on.

The following officers were elected for the ensuing year: President, Dr. W. E. B. Davis, Birmingham, Ala.; first vice-president, Dr. Edwin Walker, Evansville, Ind.; second vice-president, Dr. A. Goldspohn, Chicago; secretary, Dr. William Warren Potter, Buffalo, N. Y., re-elected; treasurer, Dr. X. O. Werder, Pittsburg, Pa., re-elected. Cleveland, Ohio, was selected as the place for holding the next annual meeting; time, second Tuesday in September, 1901.

Omaha Medical Society.

RETRO-COLONIC ABSCESS.

Dr. B. B. Davis reported a unique case of retro-colonic abscess. The patient presented the following history: He was eating pork, when he seemed to swallow a bone, which stuck in his throat and was apparently dislodged by copious draughts of water. He was comfortable for three or four days, but then had considerable pain in the right abdomen, with constipation, which resisted cathartics, and vomiting then ensued. Physical examination showed general tympanites with marked dulness on deep percussion from McBurney's point to the floating ribs. Further questioning brought out the fact that he had been feeling very poorly for several weeks and had progressively emaciated. Malignant trouble was suspected and an exploratory operation advised. Incision was made in the right linea semilunaris; the colon seemed normal, but a hard mass was found behind it and apparently intimately attached to it. After much manipulation, pus and fecal matter welled up from a large cavity. An opening was found in the colon. Drainage was used and the sinus entirely closed in about three weeks. The bone which had been swallowed was not found. The appendix and ileo-cecal junction were examined carefully and found normal. Recovery was uneventful.

GANGRENE FROM MILD CARBOLIC DRESSINGS.

Dr. Davis also reported a case illustrating the danger of gangrene from mild moist carbolic dressings. A little girl of 7 or 8 had pulled off a "hang-nail." It gave her pain and she took a solution of carbolic acid which had been used to wash the wood-work of a sick-room, moistened a cloth with it and wrapped her finger in it. The dressing was kept on over night only. Dry gangrene took place, the bones of the finger were necrosed and amputation was necessary. Investigation showed that it was probable that not stronger than a 2 or 3 per cent. solution had been used. He felt that great caution should be used as to the use of moist carbolic dressings.

Drs. Lord and Gifford spoke of similar cases. Dr. Summers felt that most of the cases arose probably from carelessly-made solutions, in which even crystals of the acid got on the dressings.

HYSTERICAL CILIARY ALOPECIA.

Dr. Harold Gifford reported three cases of this condition. Three years ago, two little girls were brought to him about the same time with eyelashes almost gone, and yet there was no ciliary blepharitis. He thought there was some trophic trouble, was much puzzled to explain it, and did nothing for them. Recently he saw one of them; the hairs were almost gone and the lids red and painful. It occurred to him that there might be hysteria in the case. He accordingly sealed up one eye with collodion; dressed it daily, used vaselin on both lids and found, after several days' observation, that a new crop was coming on the sealed-up lid. He was satisfied that the girl had continued to pull them out from the unsealed lid. The girl would not confess, but went home and had no further loss of hairs. He met with two similar cases a little later. One of these girls, 11 years of age, was entirely removed from the appearance of hysteria. The other girl, of 14, pulled out the lid-hairs and the eyelashes also. She confessed that she had seen her father pulling out "wild-hairs" and imitated him.

In the discussion which followed the question was raised whether pulling out hairs was a "habit" or an evidence of hysteria. Dr. Gifford was of the opinion that it was not a habit because it was painful. It could be stopped without difficulty, merely by telling the patients how wrong and harmful it was and threatening to notify the parents if it was not stopped.

PLACENTA PREVIA.

Dr. J. E. Summers, Jr., said that he had been called on by a doctor who reported himself as completely worn out and needed surgical assistance, and asked him to come prepared to do a Cesarean section. He went, found a woman in profound shock and pulseless; the bed soaked with blood. Examinations showed the os dilated sufficiently to admit the tips of two fingers and a centrally-implanted placenta beyond. He dilated rapidly, probably for six or eight minutes, went through the placenta, grasped a foot, brought it down, delivered the trunk, put the forceps on the after-coming head and had the satisfaction of saving the mother, but the child was dead.

AMERICAN.

2. **Gynecology, Its Present, Past and Future.**—Kelly reviews the past of gynecology, shows how we have lived through the various fads and theories, what discoveries have been epoch-making and beneficial and thinks that in the immediate future diseases of the urinary tract will first take our attention and later will follow the better understanding of diseases of the rectum and gall-bladder. There will be a closer connection between gynecology and surgery in the immediate future.

3. **Chemical Examination of Feces.**—The methods of chemical examinations of the feces are elaborately described by Austin, who shows what is likely to be found and its significance.

4. **Meniere's Disease.**—According to Burnett, chronic ear-vertigo or Meniere's disease is due to a mechanical cause consisting chiefly in impaction of the stapes in the oval window, and removal of this impaction and liberation of the stapes will cure the disease. The removal of the incus breaks the retractive force of the tensor tympani and malleus exerted through the incus upon the stapes, and the latter bonelet is liberated. In chronic purulent cases it is necessary to excise the remnants of the diseased membrana and the malleus and incus with their synechial bands in order to liberate the stapes. This incision of the diseased ossicles also has the effect of curing the chronic suppuration and preventing antrum and mastoid disease. His operation in brief consists, after sterilizing the auditory canal and membrana, and illuminating with electric light, in making, when the membrane is intact, the initial incision close behind the short process of the malleus and following the periphery closely backward and downward to a point below a line drawn horizontally through the umbo of the membrana. It is usually followed by little or no bleeding. The flap which is thus made is turned inward toward the promontory with a probe armed with sterilized cotton. If there is no bleeding, the incus-stapes joint is seen as soon as the flap is pushed aside; if there is bleeding, it should be checked with a sterilized mop. The incus being now in plain sight, it should be gently disarticulated from the stapes by drawing the former outward and downward by means of an incus-hook knife passed behind its long limb. When this is done the long limb of the incus should be grasped by special forceps and drawn very cautiously downward and outward into the auditory canal and then removed entirely from the ear. When this is accomplished the operation is finished. The slight bleeding that sometimes occurs in the chronic catarrhal cases requires no attention. The meatus should be stopped with sterilized cotton and the ear let alone for 24 or even 48 hours, unless the cotton in the meatus gets moist with blood or serum. If this occur the cotton should be removed and dry cotton inserted. There is to be no after-treatment in such cases, as all is accomplished when the incus is removed. As a rule there is no reaction in these cases, and the wound in the membrana heals by first intention. Sometimes a slight reaction has occurred, shown by a little pain and some mucopurulent discharge. But this is healed in a few days by simply mopping the ear with sterilized cotton and a solution of formalin—1 to 1000—and such reaction has never had any bad effect upon the result of the removal of the incus in checking the vertiginous attacks in any of his cases. He has never encountered a serious reaction after the operation, either in the chronic catarrhal or in the chronic purulent class. In purulent cases the operation is somewhat different, the ossicles are usually plainly visible. The incus should be detached and removed and the remnant of the diseased membrane and malleus completely incised. Hemorrhage is apt to be somewhat troublesome and constant mopping may be required. After the operation the ear requires syringing with bichlorid solution—1 to 500—and the ear should not be stopped with cotton, but allowed to discharge. The subsequent treatment may be that indicated in a case of chronic purulent otitis media. Burnett has performed this operation in twenty-seven cases of chronic ear-vertigo and in no instance has it failed to give relief.

5. **New Hemoglobinometer.**—Dare describes a new instrument for determination of hemoglobinuria, the advantages of which he briefly recapitulates as follows: An immense amount of labor is saved by dispensing with dilution and its possible errors; leucocytosis can not influence the results; adjustment is made for the color curve; the color shades for comparison are made more decided; the pipet is absolutely cleaned; and, most important of all, the readings are uniform and accurate and depend upon principles which allow the best analysis of color shades in the shortest time. Results within 1 or 2 per cent. are obtained with a certainty hardly obtainable with other instruments. Clinical patients who took a lively interest in the examination of their own blood, when asked to make comparisons, rarely exceeded a variation of 2 per cent. in successive trials. In the case of shop-girls who were accustomed to match colors the variation was still less. In considering this instrument, its simplicity, its compact construction, lightness, and portability, as well as the accurate results obtainable with it, should be taken into account.

8.—See abstract in The Journal of September 29, p. 838.

9. **Tuberculous Lymphadenitis.**—Crowder concludes his paper by reviewing the literature and finds that while we are not warranted in assuming that all pseudoleukemias are tuberculous, it is at least established that tuberculous lymphadenitis may give rise to their symptom-complex and anatomical findings. Enough examples have been recorded to show that it is not altogether an infrequent condition.

10. **Ascending Urinary Infection.**—Blumer and Lartigau report cases showing the ascending infection by the bacillus pyocyaneus of the urinary passages, a condition which has not been previously reported, nor has the association of proteus vulgaris with the bacillus pyocyaneus been heretofore noted. Several cases are reported in detail; in the first, the main symptoms were referable to the nervous system, the most important of these being partial paraplegia, loss of reflexes, anesthesia and analgesia, without any cord lesions to account for them. The subsequent development of a bed-sore and its infection by the bacillus pyocyaneus is of interest. It seems probable that this was due to urinary infection. Case 2 is a simple case of ascending urinary infection following stone in the bladder. Case 3 gives a clinical picture of hemorrhagic septicemia probably incidental to the puerperal streptococcus infection. In these cases one striking feature was the comparative nonvirulence of the isolated bacillus pyocyaneus, which the author attributes to the fact that the process was essentially chronic. In the ordinary pyocyaneus infections, which are acute, it is rare to find non-virulent forms.

12. **Pott's Disease.**—Bradford and Cotton report experiments on the effect of forcible attempts to reduce deformity in Pott's disease performed on cadavers and models, including also the questions of retention after correction, and discuss the subject. They also show the effects of treatment as personally observed in the practice of the late Dr. C. F. Taylor. In conclusion, they remark that the correction or rectification of the curve in Pott's disease is to be considered in every case of active disease with a deformity. The employment of force should depend on the pathologic conditions and not on the extent of the curve. Force should be used with great reserve. Improvement of the curve is to be attempted wherever the spinal column can be made straighter without great force. The main dependence, however, for ultimate success remains in the surgeon's careful, continued, and thorough employment of retention appliances which hold the spine in the straightest possible position for a sufficient length of time for consolidation of the diseased bony structures. Success is to be won more by careful attention to detail than by an operative attempt.

13. **Digitalis.**—Cutler calls attention to the fat-free tincture of digitalis devised by Joseph W. England, chief druggist of the Philadelphia Hospital, to meet the serious drawbacks in the use of infusions of digitalis when large doses are required

to produce the desired action on the heart and kidneys. For the past five years this preparation has replaced the official tincture in the wards of the Philadelphia Hospital, and Cutler here reproduces the clinical statements as to its non-irritating properties by Dr. D. E. Hughes, chief resident physician. Several cases are reported and in all the fifteen cases the fat-free was compared with the official tincture under the observation of Mr. England and Dr. F. A. Sherer. The author himself has not used the preparation long enough in the Massachusetts General Hospital to obtain any new data in regard to its action, but his opinion has been confirmed with reference to its usefulness. This tincture does no more than the official tincture will do therapeutically, but it does not produce the nausea and digestive disorders so frequently observed with the latter. He believes it fills an important place and reproduces Mr. England's observations to call attention of the profession to its value.

14. **Knee-Joint Surgery.**—The title of this paper is self-explanatory, it being a report of thirty-eight operations for synovial fringes, injured semilunar cartilage, loose cartilage, coagula, exploratory incision, etc. The purpose of the paper is to show that operations on joints need not be feared more than operations elsewhere and to urge their importance not only to relieve a definitely recognized condition, but also for exploratory purposes in doubtful cases.

15. **Surgical Technique.**—The results of advances in the surgical technique during the past five years in the city hospital are given by Brewer as follows: First year, number of operations, 147; deaths, 8; mortality percentage, 5.4 per cent.; infection occurring in clean cases, 39 per cent. Second year, number of operations, 109; death-rate, 8.2 per cent.; percentage of infection in clean cases, 9 per cent. Third year, number of operations, 165; death-rate, 9 per cent.; percentage of infection in clean cases, 7 per cent. Fourth year, number of operations, 191; death-rate, 6.2 per cent.; percentage of infection in clean cases, 8.5 per cent. Fifth year, number of operations, 168; death-rate, 7.1 per cent.; percentage of infection in clean cases, 3.2 per cent. From these observations the writer thinks that he is justified in saying that, if our technique is perfect, no unfavorable suppuration is to be expected and, while he is willing to admit the decreased resistance of the class of patients received and their greater liability to infection, still he thinks that by a perfect, though perhaps somewhat exaggerated, system, the results are as good as in any other hospital.

16. **Toxicity Versus Septicity.**—The action of bacterial infection is discussed by Wasdin, who divides it into two types, toxic and septic, the former including those cases which are due to toxicity from the seat of infection and the latter, those where there is actual presence in the blood of the bacteria themselves. Of the former type, diphtheria, tetanus and cholera are characteristic, and in diphtheria the colony rests always at its primary seat, disposing of its toxin through the system, and there is a wonderful local reaction, the leucocytes quickly forming a barrier of protection in the so-called "false membrane." In tetanus and cholera there is no such local reactionary collection of leucocytes, but there is no invasion of the circulation, no true septicemia. Influenza most probably is to be classed with these, though the isolation by Pfeiffer of his bacillus from the blood in some cases may require it to be classed with the modified septicemias. The infections which develop septicemia more or less primarily are lobar pneumonia due to the pneumococcus, typhoid fever, bubonic plague, tuberculosis and yellow fever. The author shows how each of these is produced, but doubts whether there are any purely septic infections as clearly septic as diphtheria is toxic. He especially discusses plague and yellow fever and maintains that both toxicity and septicity coexist in many of the infectious pathogenes. The law which governs the formation of the types of cases encountered in all of them is that the infection having taken place, the type of the disease must depend upon the development in the infecting organisms of the inherent qualities of toxicity and septicity; that if toxicity preponderate, there will result the toxemias, and if septicity be the more pronounced, the septicemias will be produced, since these qualities coexist in each infective germ, the one or the other being exhibited in greater perfection according to environment. He calls attention to the fact that this infection characterized by mixed toxicity and septicity responds but slightly to sera, while the most toxic, such as diphtheria and tetanus, and the most septic, such as plague, have been thus benefited. He thinks it likely that until it is possible to separate these qualities and to utilize the one desire, it will be impossible to produce a serum of anything like the beneficence of diphtheria antitoxin.

17. **Extirpation of the Ureter.**—This, as advised by Willy Meyer, is the complete removal of the entire ureter from just below the pelvis of the kidney to its entrance into the vesical wall. The difficulties of the operation are noted and the indications recognized for it are discussed. 1. In malignant tumor of the kidney. As far as he had learned, no such case of total ureterectomy has been reported, and it will generally, in such cases, be a partial one. 2. In tuberculosis of the kidney he doubts whether primary total ureterectomy is often indicated, though a few cases have been reported in which it was seen during nephrectomy that the ureter was very seriously affected and its partial removal would have been an incomplete operation. In the majority of these cases, however, he thinks the ureter will take care of itself if nephrectomy is performed early enough in the disease. He believes that the cystoscope might often furnish the best means of determining the indication for secondary ureterectomy. 3. Another indication would be where the original wound breaks open again and a sinus establishes itself. 4. Pyonephrosis and pyonephrotic stone kidney. It was a case of this kind which led to the origin of this paper. The case shows what mischief can be produced by a single renal calculus which can not pass the ureter, and also demonstrates the necessity of always testing the patency, especially when performing nephrotomy and nephrectomy. If the stone can be reached by the lumbar wound the surgeon should try to push it up and extract it, but if at the lower end of the ureter the organ ought to be exposed extraperitoneally if the patient's condition permits. If it does not it will probably have to be done later. He does not believe that stricture without the presence of stone which was the original cause will often necessitate the extirpation of the ureter after the removal of the kidney. In conclusion he says: "By making it a rule always to test the patency of the ureter down into the bladder when doing a nephrotomy or a nephrectomy, and then, according to the result of the examination, adding immediately or later the necessary treatment of, or operation on, the ureter, many a kidney will be saved from extirpation and much trouble be spared our patients."

18. **Hernia.**—Phelps illustrates his method of operating for hernia with the silver-wire pad. He thinks it necessary to make up for the loss of resistance that has resulted from the chronic pressure and distention by the hernia, and the material required must be one that will not be absorbed and be so elastic that it will bend with each movement of the body. The wire mattress which he puts in place is left and becomes encysted and makes that portion of the abdomen even stronger than the rest. If the wire mattress becomes infected, which seldom happens, he would fill the wound with pure carbolic acid, after curetting out the infected part, and afterward wash it with pure alcohol, which is a perfect antidote, and then allow the wound to heal by granulation.

19. **Rheumatic and Gouty Diathesis.**—According to Porter, the predisposing factors in the development of so-called gout, or rheumatism, are that the intake of nutritive pabulum is larger than the system can properly oxidize or a condition that so reduces the oxidizing capacity of the animal economy that the small amount of food taken could not be properly oxidized. Added to this, in determining the special type, are the action of the bacilli and proteids in the alimentary canal and the formation and absorption into the system of toxic products. These factors together determine the nature of the

lesions, the symptoms, abnormalities and biproducts from which we are able to differentiate the different forms of these suboxidized conditions. There are also a few other things that can not be overlooked, as changes in temperature, hygienic surroundings, nervous disturbances, etc. His arguments are elaborate and he goes into the subject in detail, especially as regards the different forms of rheumatic and gouty affections.

20. **Carcinoma of Parovarian Body.**—From a study of a specimen that was thoroughly examined microscopically and otherwise, Talmey concludes that the growth found was certainly a primary cancer, and he argues to show how any connective-tissue proliferation in the broad ligaments may give rise to cancerous growths. He believes that malignant parovarian tumors are not rare and that if all the so-called ovarian tumors were systematically examined under the microscope a great part of them would be found to be of parovarian origin.

22. **Metatarsalgia.**—This disorder, which was described by Morton in 1876, has been a subject of discussion as to its exact pathologic mechanism since the first. The author rejects Morton's explanation that it is due to pressure on branches of the external plantar nerve between the heads of the fourth and fifth metatarsals, and argues at length in favor of the following propositions: 1. That metatarsalgia is a symptom of several pathological conditions of the foot, and sometimes possibly of constitutional disorder. 2. That it is possible to completely relieve many cases without operative interference by establishing an exact diagnosis of the underlying condition and directing the treatment accordingly.

23. **Alkaline Saliva.**—The gist of this article appeared in The Journal, August 25, p. 484.

34. **Enteric Fever in Childhood.**—Blackader reports the results of observation of 100 cases of typhoid in infants, pointing out the peculiarities and the agreements with the disease as noted in adults. As a rule, the typhoid is milder under the age of 15, the duration in the great majority of cases being less than three weeks. Above 15 it generally follows the course in adults. The treatment which he advises in the majority of cases is the systematic use of water, but he does not think it necessary or desirable that so low a temperature should be employed as in the case of older persons, nor should this treatment be confined, as directed by Brand, to cases where the fever reaches 102.4 F. All sudden and severe shocks should be avoided. Even if the pulse falls below 102, he thinks the regulated use of the cool bath once or twice a day strengthens the heart's action and helps to more rapid convalescence.

35. **Soup Diet and Rectal Irrigations in Typhoid.**—On the ground of the probability that milk favors germs, Seibert has attempted the use of other fluids, such as soups. At the beginning of the attack he gives plain cold water for twenty-four hours after the initial purge, then soups made of meat-broth, containing oatmeal, barley, rice and peas, strengthened, of course, with spices, and later lentil soups with eggs. Five meals in all were given during the day preceded by 5 to 15 drops of diluted hydrochloric acid, unless hyperacidity prevailed. No other medication was employed, but two to four warm-water enemata were given daily. The results were the disappearance of headache, delirium, nausea, insomnia, tympanites, vomiting and fur on the tongue; the appetite returned frequently on the fourth day of treatment, even when considerable temperature existed. Excessive diarrhea even disappeared invariably within one week. In all uncomplicated cases the temperature began to decline within twenty-four to forty-eight hours after the beginning of treatment, and invariably reached the normal within ten to twelve days. In cases complicated by pneumonia, nephritis or phlebitis, the temperature generally remained in accord with this condition until it disappeared, while the cerebral, gastric and intestinal disturbances subsided as rapidly as in uncomplicated cases, excepting only the anorexia. Complications, when not present at the start, were very rare, usually appearing in the first two days. Intestinal hemorrhage was noticed in three cases, none ending fatally; perforation did not occur. In all of the 153 cases treated in this manner there were seven fatalities; three patients were brought in moribund and four had complicating bilateral pneumonia.

37. **General Subcutaneous Emphysema.**—Cotton reports a case of this condition and remarks on its rarity and its fatality. He suggests that relief of the cough and the restriction of respirations were indicated and that incision and drainage are possibly advisable.

44. **Cubitus Varus.**—This condition, which consists in marked permanent adduction of the forearm, has been studied by Stimson, both in specimens and by skiagrams. He says he can not escape the conclusion that the close resemblance in a chance collection of six cases and their easy experimental reproduction, with almost total absence of specimens showing lesions of another kind, justify the belief that the common anatomical cause of cubitus varus is not ascent of the internal or descent of the external condyle after fracture extending into the joint, but that on the contrary it is an angular displacement of the entire lower end of the bone after a supracondyloid fracture, or of its lower portion after a fracture which is practically a partial separation of the cartilaginous epiphysis, especially on its outer side. He suggests for the correction of the deformity pressure outward and downward against the olecranon in rectangular flexion of the joint, or adduction of the fully extended forearm and maintenance of the latter position for a week or two, which would probably be the surest means of preventing recurrence, but it should be combined with confinement to bed.

45. **Castration and Vasectomy.**—Wood has collected a large number of cases where castration or vasectomy was performed for prostatic enlargement, from which he concludes that there is ample reason for advising and performing one of these operations in suitable cases.

46. **Massage in the Treatment of Periarticular Fracture.**—Woolsey has used this method in a number of forms of periarticular fracture and with his increasing experience he is more than ever satisfied with the results. He says he has seen no advantage in discarding splints in the early part of the treatment, as they give a sense of security. We should pay particular attention to the position of the limb in carefully reducing any deformity, and keeping it reduced during massage and between the periods of massage when the limb is in the splint. If this is not possible from the outset, after a preliminary massage, a plaster cast should be applied and kept on from eight to fourteen days, when massage should be commenced. The results in these cases are better so far as position is concerned, equally as good functionally and nearly, if not quite, as quickly obtained as when massage is employed from the first. If, again, after massaging for some time, the position is not found to be correct, or, if after three weeks quite firm union has not taken place, he believes in using the plaster splint for from eight to fourteen days, though the functional result may suffer some delay. He thinks the treatment of fractures, especially articular and periarticular fractures, with the above restrictions, by massage and passive motion gives the best and quickest results as to bony union and function of any method in vogue.

47. **Mynter's Method of Wrist Excision.**—Mynter's method is slightly modified from that originally proposed by Studsgaard, and consists in making a longitudinal incision between the third and fourth metacarpal bones, thus opening up the wrist-joint between the os magnum and unciform bones and between the semilunar and cuneiform bones. Mynter's modification consists in splitting the hand between the second and third metacarpal bones and thus entering the wrist between the trapezoid and os magnum and between the scaphoid and semilunar bones. The dorsal incision reaches up to the radius and the palmar incision not farther than the base of the thenar of the thumb. Taylor has tested this method and reports a case, with skiagrams and photographs of the results, which seem very good.

50. **Anesthesia and Circulation and Respiration.**—Kramer has experimented on animals as to the effect produced on the circulation and respiration by irritation of a sensory nerve during anesthesia. The methods are described, and in one dog, where no anesthesia was employed, the cardiac respiration was increased by 50 per cent., and the inspiratory effect was greatly increased. The cardiac rhythm was also increased approximately to the same extent and the blood-pressure invariably rose. This experiment was not repeated, as others had found the same results. When the animals were deeply anesthetized, so that there was no corneal reflex, the results were very different. In most cases the irritation of the central end of the crural nerve was without effect either upon the circulation or respiration. When the animal, however, was only partially anesthetized, the respiration became greatly accelerated and increased in amplitude, while there was a marked fall in the blood-pressure, which may possibly have been preceded by a slight rise. The conclusion drawn from these experiments is that severe vasomotor shock is more liable to follow operation with partial anesthesia than when done under complete insensibility.

51. **Fracture of the Lower End of the Radius.**—This paper by Cotton, which is concluded from a former number, is too detailed to be abstracted satisfactorily and the reader is referred to the original.

52. **Antitoxin Treatment of Tetanus.**—Moschcowitz's article gives additional cases, ending with No. 290, of tetanus reported which were treated with antitoxin. He finds a mortality of 40.33 per cent. Of the cases with a period of incubation of less than 5 days, 9 recovered and 41 died—a mortality of 42.42 per cent.; of 114 cases with a period of incubation from 5 to 10 days, 52 recovered and 62 died—a mortality of 54.38 per cent.; of 64 patients with a period of incubation from 10 to 15 days, 52 recovered and 12 died—18.75 per cent. mortality; of 24 cases with a period of incubation over 15 days, 20 recovered and 4 died—20 per cent. mortality, and of 55 cases with unknown or unreported incubation, 30 recovered and 25 died—a mortality of 45.45 per cent. The total number treated by intracerebral injections was 48, of which 23 recovered and 25 died, or a mortality of 52.08 per cent.

55. **Some Nervous Problems.**—Langdon first notices the neuron theory, the utility of which he points out, and also the fact that it was somewhat anticipated in 1874 by a personal friend of his, Dr. Samuel Spahr Laws, of Bellevue Hospital Medical College, in a graduation thesis. The first problem which he offers relates to locomotor ataxia and its causation. This, he suggests, may be only a result of heredity or acquired vulnerability of the peripheral sensory neuron system. The tabetic type of individuals has impressed itself upon him. There is a marked similarity in the build, temperament and nutritional defect in the great majority of these patients. He reasons that some other factor than syphilis must be predominant and suggests, rather ingeniously, the assumption of the upright position by man requiring greater delicacy and equilibrium and consequent tax on the neurons, with the special conditions of civilization as making greater strain upon the organs. His theory as carried out involves the idea that chronic degeneration or tabes must commence high up in the cord or in the oblongata. Another disease where motor neurons are especially affected is primary lateral sclerosis, of which he recognizes a purely acquired form occurring in late maturity. He applies the rule "late to develop, early to decay" and thinks that, according to this, it should be more common, and the reason of its rarity is man's indisposition to exert the neuron. All the cases he has observed were in men who had seen military service with its special fatigue and exertions. Another condition noticed is combined sclerosis. He concludes his article with two propositions which he thinks demand recognition: 1, that the most important problems we have to solve are those connected with the individual differences in patients and their environments; and 2, that since it is mainly through neurons that these differences are manifested, both in a psychic and somatic sense, in the expression and elucidation of symptoms as well as in the action of remedies, the solution of the corresponding problems rests largely with the neurologist and psychiatrist. The paper is difficult to abstract without great elaboration, but it is suggestive and interesting.

59. **Gall-Stones.**—Richardson's article is a very lengthy discussion of very many of the surgical aspects of gall-bladder surgery and is too detailed to be abstracted.

60. **Latent Infection.**—Adami takes up the subject of the existence and fate of bacilli in the blood and tissues, and from a thorough discussion of the researches that have been made comes to the following conclusions: There is a passage of leucocytes through the mucosa of the alimentary tract and these, while in part destroyed, in part find their way back, bringing with them food particles, among which may be bacteria present in the intestinal contents. During the active congestion which accompanies digestion the passing out and return of these cells is increased and the germs find their way either through the lymphatic canals or portal system. In either of these they tend to be destroyed by leucocytes. By the employment of adequate methods it can be demonstrated that even in the healthy kidney and liver, in a large number of cases, in rabbits at least, a certain number of microbes are living in any one moment, so that cultures can be obtained from the organ on its removal from the body. It is probable, further, that in health a certain number of bacteria which have not been destroyed by leucocytes pass through the liver into the systemic blood. These tend to be removed by the kidneys and possibly by other glandular organs. In any case the ordinary methods at present employed in making cultures from the blood are insufficient to detect their presence unless they are in such number or of such a nature that they are not altogether destroyed by the bactericidal action of the shed blood. From these conclusions he infers that there is a latent infection—what the French term a latent microbism—that is, a condition in which residing germs are, under favorable conditions, excited into activity. This seriously involves surgical operations as well as other pathologic conditions. He also concludes that at the moment of death these bacteria are multiplied and also that there is a condition of what he calls subinfection in which the tissues destroy germs, but from constant invasion become worn out and chronic or acute infection may supervene. He illustrates his views by the conditions of hemochromatosis and pernicious anemia.

62.—See abstract in The Journal, xxxiii, p. 1419.

63.—Ibid., xxxiv, p. 363.

66. **Vibratory Massage in Deafness.**—Lucae describes an instrument contrived by him for massage, and the results of the treatment. The summing-up of his experience is given that the best therapeutic results will be obtained by the application of the simple hand masseur; although the number of vibrations are limited, yet it has the advantage that each stroke can be controlled by the hand and it is free from many of the objectionable features of other instruments.

67. **Bilateral Abductor Paralysis.**—This article is a plea for an early operation in case of bilateral abductor paralysis of the vocal cords. The author reports cases and has searched the literature, in which he has found 88 cases recorded. In addition to these he has learned of 30 more by letter, only a few of which had been published, making a total of 118. He would not have every case of abductor paralysis tracheotomized or intubated at once, but is against procrastination, as the patient may be lost. Of the 30 cases tabulated, 14 were operated on, while 13 had no operation, and 3 were lost sight of. Of the 14 cases operated on, 10 recovered, 1 died and 3 drifted away. Of the 13 not operated on, 7 recovered, 3 died and 3 were lost sight of. Four of the 7 recoveries were not true paralysis of the abductors, but occurred in neurasthenics, which leaves the percentage of recoveries very small.

68. **Septal Irrigations.**—The occurrence of slight septal abnormalities is so common that the teaching to operate upon them is not generally accepted. Pynchon thinks, however,

that they are liable to make trouble, and advises their removal. He gives in conclusion his views as follows: Slight prominences of the nasal septum, which through heightened color of the lining mucous membrane give evidence of chronic inflammation, are to be reduced as nearly as possible to the normal plane of the septum.

69. **Nasal and Post-Nasal Synechiae.**—Price-Brown thinks that these false bands are rarely congenital and nearly always traumatic. They are often due to surgical interference and he considers the galvano-cautery as the form of this most liable to induce their development. He reviews the various causes of this accident and refers to some cases in his own observation, and remarks as to prognosis that this depends largely on the width of the cavity traversed by the synechiæ. When it is not narrow, treatment may be unsatisfactory. In the bony forms he has found the saw the most useful instrument; for fibrous synechiæ he uses the knife, scissors or curved nasal knife. Any hemorrhage occurring at the time he considers as an advantage. He does not like gauze for tampons, but prefers absorbent cotton soaked in one of the hydrocarbon oils, and left *in situ* for several days. He does not use aqueous sprays at all, but hydrocarbon oils thrown through the atomizer by means of compressed air.

74. **Normal Salt Solution for Pleural Effusions.**—Robison remarks that there is nothing so perplexing as to have to deal with cases of chronic non-tubercular pleurisy with effusion that do not subside after repeated aspirations. He has found in such cases injections of hot normal salt solution of great advantage not only in improving the general condition, but in aiding the carrying off of the effusions. The *rationale* of the treatment is simply: 1, To increase osmosis of the fluid into the blood vessels and the activity of the absorbent lymphatics. 2. It is also a solvent and antiseptic. 3. It has a stimulating effect on the pleural vasomotor nerves, dilating the capillaries and hastening the blood-current.

75. **Hallux Valgus.**—Keller operates on this condition in the following manner: Incision over the enlarged head of the metatarsal parallel to its axis, but not extending forward onto the phalanx, the cartilage of which is carefully preserved. All the structures are pushed aside, the joint opened and the end of the metatarsal removed sufficiently for the toe to come back to its place. About three firm catgut sutures are passed through the tissues adjoining the bone of the toe and metatarsal. These do not extend through the skin, but are entirely buried and, when properly adjusted, help to keep the toe in the correct position. The skin and outer structures are closed with interrupted silkworm gut sutures and gauze dressing applied. A light splint is placed on the inner side of the foot and the whole bandaged. No drainage is needed, and the dressing need not be changed for ten days, when the external stitches are removed and the dressing reapplied. If asepsis is good—and one would better not operate without it—earlier change of dressing is not required. In two weeks the patient may be allowed to walk a little on the outer side of the foot slowly but gradually coming to the normal use of it. In his practice recovery has been complete in from six to eight weeks.

76. **Food Adulteration.**—The importance of food adulteration, especially as regards the health, is noted by Leuf, who details some of which he has learned. Mustard is adulterated in several ways, either by extracting the essential oil and deteriorating its quality, or by mixing it with foreign substances from 30 to 60, or even 75, per cent. The average adulteration is about 50 per cent., and this applies to spices as a class. Pepper, especially the white, is adulterated with cracker dust and a little cayenne pepper. In cinnamon we have wholesale adulteration by cassia bark, and when adulterated in the ground article they use cracker dust and cedar sawdust. Ginger is first weakened and then adulterated, the principle is extracted by alcohol and then it is further weakened by the addition of cracker dust, starch and a little cayenne pepper. Cloves are sometimes deprived of their oil and then adulterated, and allspice is not less so, since it is hardly possible to get anything better than half strength in the market. Together with the removal of the essential oil, the remaining product is mixed with the common adulterants. Nutmegs and mace in the powdered form are often adulterated in this way and artificial nutmegs powdered and scented to suit are also on the market. Cayenne pepper itself is also sophisticated, which he thinks must be done through general meanness, as it hardly pays for the trouble.

82.—This article has appeared elsewhere. See The Journal of August 4, p. 267.

90. **Trachelorrhaphy.**—Palmer here describes a new method of performing trachelorrhaphy, which consists in inserting the sutures and passing them around a broad ring encircling the cervix, which keeps the parts together, and tying the suture outside it. It is then held in place and proper coaptation thus kept up by uniform pressure around the entire circumference of the cervix.

96. **Uterine Cancer.**—Eastman calls attention to the importance of endometritis due to abortions, prevention of conception, and unnatural modes of life, and of cervical lacerations as favoring malignant disease of the uterus, but he does not consider these as the sole causes. He thinks, however, that attention to these will materially reduce the death-rate from this class of diseases.

98. **Perforation in Typhoid.**—After reporting several cases, Davis discusses the condition and the form of operation. He would make the incision obliquely to the internal side of the anterior superior spine of the ilium, where the cecum at once presents, and by drawing it out the ilium follows and can be examined. The summary of his paper is given as follows: The diagnosis of perforation is not always easy. A decided and sudden increase, especially of pain, in the abdominal symptoms, associated with an abrupt fall of temperature, is diagnostic of perforation. Leucocytosis is a confirmatory sign. Hemorrhage is accompanied by a sudden fall of temperature, but not by a sudden increase of abdominal symptoms. Dulness in the right iliac region is not to be expected in cases of perforation. Localized impairment of resonance may be due to free abdominal fluid; change of position causes it to disappear. Localized pain and dulness may be due to a plastic peritonitis around the site of perforation. This may be observed perhaps in one case in ten, possibly one in five. It is impossible to recognize that a perforation is about to occur. It is not necessary to operate before a perforation occurs, but operation must be done before collapse is marked. Typhoid-fever patients, when not in total collapse, are liable to die on the table. He knows of some such cases. Washing out the abdominal cavity with hot normal salt solution, even if no perforation is present, seems to improve the condition of the patient at the time of operation, and to favorably influence the subsequent course of the disease. Operate as soon as the diagnosis of perforation is made. It is less dangerous for the patient to run the risk of having an operation done during the first period of depression, than to wait and run the risk of having collapse preclude all operative measures. In operating incise as for appendicitis, and not in the median or semilunar line.

101. **Serum Therapy.**—First remarking that five deaths have been reported out of some millions of cases where antitoxin has been used, Cott discusses the observations that have been made as to the extreme amount that has been given and the occasional untoward effects. He calls attention to the effect upon the kidneys, and his argument is that this is probably due to the antiseptics in the antitoxin solutions. The least danger is apparently in those preparations where trikresol is the antiseptic and the greatest danger, probably, in those where carbolic acid is used. He thinks that in these cases the irritant which is largely excreted by the kidneys intensifies the destructive processes going on in an already existing nephritis and may cause the death of the patient.

102. **Feeding in Stomach Disease.**—Murdoch reports and illustrates a case of chronic dyspepsia with extreme emaciation which was caused from the fear of food. By careful feed-

ng with three solid meals of dry toast with plenty of water nd chopped steak, and three liquid meals of boiled milk, the atient's condition was vastly improved, as shown in the illusrations given. To assure him that food was not his worst nemy, he washed out his stomach some few hours after a meal f solid food and when the patient saw the water returning lmost clear, instead of being mixed with undigested food, he vas convinced that his stomach was doing its duty.

FOREIGN.

British Medical Journal, September 15.

A Discussion on Puerperal Fever in Relation to Notiication.—The discussion was opened by Dr. D. Berry Hart, vho stated the objections to the notification of puerperal fever. First among these he placed the difficulty of determining what s meant by the name, and in this connection he described hree varieties: 1, the acute, rapid form due to a large amount of poison, and usually associated with severe injuries or exensive retention of the membranes; 2, the ordinary lymphatic orm, which is the commonest one, and which usually yields o local antiseptic remedies, but may end in localized cellulitis, r in death if the sapremia be intense; 3, the venous form, vhich taxes the physician's diagnostic skill most. There is iere a streptococcic infection of some clot in the uterine wall vhich causes the general symptoms without giving much, if ny, local indication, and is followed by pyemic affections of he other parts. Typhoid, tuberculosis, scarlet fever or drain oisoning may all suggest themselves. The Widal reaction ielps us as regards the typhoid fever, but as to the other conlitions, he thinks there is still some chance for mistakes. He ias not hitherto thought it right to demand bacteriologic liagnosis in private practice, but he mentions the sign given y Whitridge Williams, which may be of some use, viz., the oughening of the uterine walls indicating infection with putreaction organisms, while if smooth the existence of streptococic infection is rendered most probable. The risk of statistics eing misleading from erroneous diagnosis he considers a minor natter, as physicians will not rashly diagnose puerperal fever, nd the death certificate will give an additional check. The upposed unwillingness of the practitioner to report such cases vhen death does not seem probable is a much more serious objection, and he would make the notification a privileged comnunication, the local health officers not being required to visit he house unless the case be one in the care of a midwife. The dvantages of notification seem to him most obvious, and he s, therefore, strongly in its favor. In the following discussion, Dr. W. J. Smyly thought the notification of puerperal fever night cause great injury to the attendant and Dr. A. V. Macan believed it impossible until it becomes the rule of the profession to inform the patients and their friends what is the matter with them. It is well known that this is not an invariable custom at present. The advantage of the notification is either for the good of the patient herself or to prevent the spread of the disease to others, and he asks how the notification can do the patient herself any good. On the other hand, how will it stop the spread of disease to others more than the ordinary precautions taken by the educated physician in such cases? In the case of midwives, they need instruction, and in his opinion the first step toward lessening the amount of puerperal fever is by the improvement of the education of the doctor and midwife, and not by compulsory notification. Dr. Helme, of Manchester, remarked that it has been so persistently explained that in every case of puerperal fever the physician is the sole and blameworthy cause, that at the present moment, in many districts, to tell the friends that the patient had the disease would permanently injure the medical attendant. He suggested, therefore, that if the rule of notification is to be followed, we should first correct the erroneous opinion of the public in this regard. There were other differences of opinion, but the following resolution was carried unanimously; "That it be a recommendation to the Council that, in the opinion of the meeting, it is desirable that notification of puerperal fever (septicemia) should be adopted generally."

Observations on Human Placentation in the Second Stage. CATHERINE VAN TUSSENBROEK.—The writer's conclusions are as follows: 1. The macroscopical form of the human placenta is accomplished about the sixth month of pregnancy. 2. At that period the decidua reflexa has almost totally disappeared. 3. The reduction of the decidua reflexa is the effect of mechanical pressure. 4. The reduction of the villi of the chorion leve is chiefly effected by the obliteration of the intervillous spaces between chorion and reflexa.

A Discussion on the Natural History of Fibroids and Recent Improvements in Their Treatment.—Alban Doran, in opening the discussion, considered the following questions: 1. The natural history of uterine fibroid. It is not a fibroma. It is always more or less a myoma consisting of muscular fiber like the uterus, and while nobody would think of treating a fibroma with internal medication, it is a fact that ergot acts to some extent on the myomatous tissue as it does on the uterine muscle. It may, therefore, be very beneficial, but these forms are not rarely associated with cardiac disease and then ergot is contraindicated. A more important practical point is the relation of the ovaries to fibroid disease. While no definite changes have been detected in the ovaries the experience of a formerly popular operation shows that the removal in certain cases reduces the fibroid or checks the bleeding. The results, however, are not uniform, but are of some interest to us as bearing on the question whether the ovaries should be left in case of hysterectomy for this cause. 2. We are not quite clear as to the nature of the hemorrhagic discharge in fibroid disease. 3. One of the most puzzling questions is in regard to their growth; the prognosis on this point is extremely difficult. Undoubtedly spontaneous disappearance may occur or the tumor may at least remain stationary, while all other pelvic and abdominal tumors are clinically, if not also pathologically, malignant. The influence of the menopause is also of importance. It is generally believed that a fibroid ceases to grow after the change of life, but Kleinwächter finds from extensive clinical evidence that this is not absolutely true. It seems clear, however, that the menopause is apt to be retarded often until after the fiftieth year in subjects with fibroids. The majority give no trouble after the menopause, only a minority require further attention. The second subject which he discusses is the recent improvements in the treatment. He asks first if there are any recent improvements in expectant treatment. We have advocates of electricity, and the bromids, and he asks the opinion in regard to this matter. The majority of fibroids require no operative treatment, but where this is not so he discusses the various methods. Retroperitoneal hysterectomy is the most popular method in Great Britain at the present time, and he concludes with some remarks in regard to its merits and details. He objects to leaving intraperitoneal ligatures or sutures connected with the stump and finds it best to unite the cut edges of the peritoneal flaps with a continuous Lembert suture of fine silk. As regards the leaving of ovaries, he thinks it does not entail very formidable results and thinks the dread of removing the ovaries a fashion, though on surgical grounds he saves them if possible, not through fear of the consequences, but because the surgeon should remove only what is absolutely demanded. He thinks that retroperitoneal hysterectomy is the best of recent improvements in the radical treatment of uterine fibroids. Panhysterectomy entails more dangers at the time of operation and the ligatures can not be dispensed with.

On Dilatation of the Pupil from Stimulation of the Cortex Cerebri. JOHN HERBERT PARSONS.—The author offers the following as a summary of the principal results of his experiments: 1. Dilatation of the pupil, like other effects of cortical excitation, is best obtained with slight anesthesia. It often occurs without any movement either of the eyes or body, but most when the animal is struggling; it is never seen with deep anesthesia. 2. It is obtained only from those parts of the brain which are concerned in eye movements—that is, from the anterior part corresponding to the frontal [illegible] ar[illegible] he eye muscles, and from the posterior [illegible] occipital "visual center." The frontal area in the dog and cat is in the neighborhood of the crucial sulcus, and the pupil effect is usually best obtained from the mesial surface of the hemisphere at this point. The occipital area is the posterior part of the second external convolution (Ferrier's). 3. When well marked, the dilatation of the pupil is accompanied by all the usual effects of stimulating the cervical sympathetic. 4. The effect is usually more marked upon the opposite eye. 5. The effect is diminished, but by no means abolished, by section of both sympathetic nerves in the neck. The other sympathetic effects are abolished. 6. The effect is abolished by section of the oculomotor nerves intracranially, subsequent to section of the cervical sympathetics. Under these conditions the pupils assume the position of post-mortem equilibrium and are immobile. Hence, I conclude that in the absence of the sympathetic channels the diminished effect is due to inhibition of the tonic action of the third nerves. 7. The effect is not abolished on either side by the section of the corpus callosum. Stimulation of the cut surface of the corpus callosum results in the usual bilateral pupilary reaction. 8. Stimulation of the central end of a cut afferent or mixed nerve—for example, sciatic—still causes dilatation of both pupils after section of both cervical sympathetics—that is, a reflex inhibition of the third nerves. 9. He has not as yet obtained unequivocal constriction of the pupils from stimulation of the cortex, but not much attention has been paid to this point hitherto.

The Lancet, September 15.

Heatstroke in India and Examination of Some Statistics Relating Thereto.—W. J. Buchanan.—This article is largely a criticism of a paper by Dr. Sambon on "Sunstroke as an Infectious Disease." Buchanan takes up the statements contained in said paper as follows: New arrivals are more liable to be attacked than natives or old residents. He admits this to be true, but claims that it only represents a part of the truth. Recklessness and carelessness are characteristic of new arrivals in any hot country, who neglect precautions, but grow more careful with length of residence. There is no acclimatization, as Sambon seems to think, and in spite of precautions, the individual seems to become more and more liable to the effect of the heat until in time his percentage liability, as shown by statistics, becomes equal at least to that of the inexperienced newcomer. The next statement of Dr. Sambon, that siriasis is not always to be found in the warmest regions, is erroneous, as Buchanan attempts to show by figures. He finds that the incidence of fatal cases of heatstroke is greatest in the parts of India where the night and day heat is fiercest, and is also the most prevalent in the months when the heat is greatest. He also found that altitude has not the effect claimed by Sambon; in fact, the danger of sunstroke is greatest in levels above the lowest and altitude enters into the matter only when we come to a point where the elevation is combined with coolness of the atmosphere, as in hill stations. There is no analogy in its distribution with yellow fever, and the statement that its altitude range is more restricted than that of the latter disease is not true. He thinks that it will require much more evidence than that which has been produced to make those who have had experience in India accept the microbial or any other theory which seeks to minimize the great and predominating influence of fierce and continuous heat.

Presse Medicale (Paris), September 15.

Cod-Liver Oil in Tuberculosis. A. F. Plicqué.—The fresh air rest cure is tolerated by tuberculous patients only on an extra amount of food, and especially of fats, to counterbalance the effects of the cold. The struggle in the organism against the bacilli is chiefly the task of the leucocytes, which derive their energy from phosphorus. Consequently the benefits of cod-liver oil in this disease may be attributed to the action of a very easily assimilated fat, to the special combination of phosphorus, to the liver antitoxins contained in the oil, or to all combined. It is utterly useless and only fatigues the stomach when administered in small doses. An adult should take at least 100 gm. a day to derive any real benefit. Jaccoud has been most successful with 200 to 250 gm. a day, commencing with a small amount. It should always be taken in two doses, or, better still, in one dose, at the commencement of the midday meal or before breakfast, followed by a highly seasoned dish or an orange or lemon, if necessary. The oil should be fresh, and cooled if preferred. To disguise the taste a quarter of a glass of strong beer may be mixed with it, or a spoonful of syrup of ether, which assists in its digestion by stimulating the production of pancreatic juice. The addition of 1 or 2 gm. of strychnin may also facilitate tolerance. If the oil induces diarrhea or greasy stools, it is best to suspend it for a few days. It is useless to give it if large quantities are expelled unchanged. Ether or pancreatin may assist in the intestinal digestion. When percussion shows that the liver is becoming hypertrophied and soft, after long and successful administration of the oil, it is an indication of saturation and is soon followed by gastrointestinal intolerance. Remarkable tolerance for the oil during the hot weather has been observed in a few instances, but in general it should be replaced with butter, yolks of eggs, etc., at this season.

Progres Medical (Paris), September 28.

Tunnel Treatment of Abscess in Bones. L. Longuet.—Instead of the usual extensive evacuation and scraping of a circumscribed infected focus in a femur, Longuet drills into the abscess, thus making a well, as he calls it, about 25 mm. in diameter. He then drills through the bone from beneath, or low down on one side, until he enters the bottom of the well, thus tunnelling the bone completely and providing an outlet for the secretions at the lowest point. A rubber drain wrapped in gauze is passed through the tunnel. This method avoids all unnecessary mutilation of bone and soft parts; two longitudinal incisions in the skin are sufficient. The relief from pain is immediate, whether it is a case of ordinary abscess, of osteoneuralgia or of an unlocated abscess. In future cases he proposes to disinfect the tunnel with superheated air. One of his patients was cured completely by this treatment, without even a fistula; the remainder have been lost sight of.

Semaine Medicale (Paris), September 12.

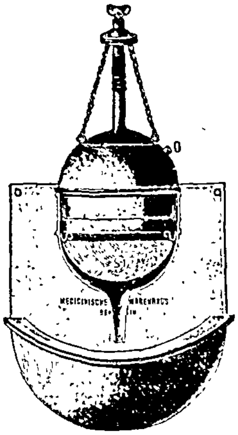
Cyanosis of the Extremities in Brain Disease. F. Leclerc.—Cyanosis of the extremities is pre-eminently a nervous trouble and is usually observed alone or as an accident of hysteria. But in certain cases it appears in the company of other symptoms with which it has certain family traits, all originating in the vasomotor centers of the medulla and adjacent centers on the floor of the ventricle. In a case described, the patient was a man of 35, with a neuropathic heredity, who suffered from almost daily attacks of vertigo, distress and eructations, although free from organic disease. Occasionally the seizures were accompanied by extreme cyanosis of the extremities and transient glycosuria.

Centralbatt f. Chirurgie (Leipsic), September 18.

Restoration of Mobility in Ankylosed Joints. V. Chlumsky.—The production of a flail-joint is usually due to the insertion of some portion of the soft parts between the parts of the joint. If this could be artificially accomplished in a joint threatened with ankylosis, the latter might possibly be prevented. Chlumsky has been experimenting on animals to determine the feasibility of such a procedure and, although his research is not concluded, the results are so encouraging that he announces them without further delay. After resection of portions of the soft parts and bones of a joint on the hind leg of a dog or rabbit, he inserted a thin triangular plate, with rounded edges, to prevent the formation of adhesions, suturing it to the sawed surface of the tibia. The plates were made of rubber, celluloid, silver, tin, gauze or a coating of collodium. The joints healed well with normal flexion and only a slight restriction to complete extension. The celluloid and rubber plates were unaltered and only slightly displaced when the animals were killed, four and a half months later, but the silver and tin had become disintegrated. In another series he used absorbable material, chiefly magnesium. The functional results were equally satisfactory, but as the thin sheet of magnesium was absorbed so rapidly, the space left was small and threatened to become closed ultimately. Further experiments with thicker plates are now under way.

Deutsche Medicinische Wochenschrift (Leipsic), September 6 and 13.

Sieve for Feces. I. Boas.—The little apparatus described screws on a faucet like a filter. The water as it enters spreads out over the small sieve "S" above and thoroughly washes the fecal matters, which are placed on a fine hair-sieve in the lower part. An opening, "O," admits a glass stirring rod. In ten to twenty minutes nothing is left on the sieve but the colorless, insoluble matters, which can then be examined at leisure.



September 13.

First-Aid in Injuries of the Eyes from Lime. H. G. Stutzer.—As time is of much importance when the eyes are injured with lime or mortar, there should be no delay nor hesitation in removing the caustic and therefore Stutzer recommends water for the purpose. The injured person should lie on the ground, another should open the eye wide, pulling down the lids with his thumbs and holding them open while a third pours water into the eye from a height of about twenty inches, using a pail or coffee-pot, preferably with a spout, and trying to make the stream as narrow as possible. The patient should then be taken to a physician, a specialist if possible. The clumsiness of the workmen in opening the eye is not a disadvantage, as the particles of lime are dislodged by the manipulations and are more readily washed out. Illustrated circulars with these instructions should be posted where lime is being used.

Cured Cases of Peritoneal Tuberculosis. Cassel.—If fever continues in a case of tuberculous peritonitis in a child after several weeks of appropriate treatment, the abdomen does not diminish in size and the emaciation progresses, Cassel summons the surgeon without further regard to the nature of the tuberculosis. He has had 18 cases in children under 11, including 3 between 12 and 18 months. Out of the 18 only 2 recovered spontaneously, 3 died and 5 were removed by the parents. Three of the 7 operated on are in perfect health—2 four years and 1 three years—after the intervention. The remainder are still under treatment.

Muenchener Medicinische Wochenschrift, September 11.

Bacterial Capsules as a Means of Differentiation. I. Boni.—It has been impossible hitherto to detect a capsule on certain bacteria when grown on solid media. This is due, as Boni has established, to the lack of color in the background. Substituting bouillon for the water used the capsule stands out distinctly, and thus aids in the differentiation of the bacteria. The typhoid bacillus has no capsule, while by this means one is clearly perceived on the bacillus coli. The medium found most effective in developing a capsule is a mixture of the white of an egg, 50 gm. glycerin and two drops of formalin, shaken and filtered. This mixture keeps well and promptly determines whether the bacterium has a capsule or not.

Test of Waning Vitality of Cells. Bioscopy. M. Neisser and F. Wechsberg.—The reducing capacity of living cells and organisms, the power to decolorize a solution of methylene blue, for instance, is proving an excellent means of determining the degree of vitality of the cell. (See The Journal, September 29, p. 850.) The authors of this communication have been testing this bioscopy, as they call it, on non-motile cells, etc., for instance, tracing the injury inflicted on kidney cells by studying the reducing power as graduated amounts of alcohol are added. The chief merit, perhaps, of the new method is the rapidity with which the efficacy of specific sera or chemical or physical agents, in respect to the destruction of bacteria, can be determined. Anthrax bacilli, for example, reduce methylene blue very rapidly, but the addition of rabbit serum, which is bactericidal for anthrax, arrests the reduction and the stain remains bright. The method can also be applied to determine growth-fostering media. Living tubercle and typhus bacilli, cholera vibrios and staphylococci possess marked reducing power, but it was absent in the toxins or ferments examined. The test can also be used for milk, to determine the microbian contents, by adding methylene blue to graduated amounts of milk, pouring a layer of liquid paraffin on the surface and placing in the incubator.

Wiener Klinische Wochenschrift, September 6 and 13.

Disturbances in Metabolism in Nurslings. M. Pfaundler.—The research on infants with gastrointestinal affections reported in this communication does not confirm Czerny's hypothesis of acid intoxication, i. e., increased excretion of ammonia and diminished elimination of nitrogen. On the contrary, it showed that the oxidating power of the affected liver parenchyma was very much diminished in these cases. The insufficiency was revealed in the products of metabolism, while in the adult and in animals, diseases of the parenchyma seldom entail functional insufficiency appreciable by the metabolism. Nine positive results in ten cases in which the examinations during life had been confirmed by the post-mortem findings, established that the variations in the oxidating energy of the liver have an influence on the nitrogen in the urine of nurslings. A decrease in the fermentative oxidating power of the organ, such as occurs with severe anatomic alterations in the parenchyma of the liver, is accompanied by increased excretion of ammonia, while the amount of urea is diminished.

September 13.

Present Status of Radiotherapy. E. Schiff and L. Freund.—Summarizing the experiences of the last few years in Roentgen therapy, the results show that it is superior to all other methods of treatment for sycosis, favus and other inflammatory or parasitic affections of the hair-covered portions of the skin, by the rapidity and thoroughness of the cure, dispensing with dressings and medicines. When operative treatment is rejected in lupus or would require too extensive intervention, the "bloodless, painless, mild Roentgen treatment enters on its rights." It respects all the sound tissue, requires no hospitals or drugs, and although longer and less certain than operative treatment, is preferable for certain cases. Roentgen treatment has the advantage over Finsen's method that the entire affected surface can be treated at once. In the treatment of hypertrichosis, it has proved effective and painless, but it leads to the formation of small atrophic depressions in the skin at the mouths of the follicles. They are not noticeable, however, and would be recognized only by an expert. Electrolysis is perhaps preferable for small hairy warts and nevi, but for extensive hair-covered surfaces Roentgen treatment should be preferred unconditionally.

General Concentric Franklinization. Breitung.—The patient is placed in a lattice-work cage, the "pavilion," which has wires running throughout the inside, discharging the positive electric breeze, and thus subjecting the patient to a concentric electric-air bath. Neurasthenic subjects are overcharged with negative electricity, and experience great relief and well-being when this is substituted by the positive. The benefits of this "pavilion" treatment have been so pronounced in Breitung's experience with nervous affections of various kinds that he recommends it as a special boon to the general practitioner.

Gazzetta degli Ospedale (Milan), August 26 and September 2 and 9.

The Iodophile Reaction of Pus Corpuscles. V. Porcile.—Wherever the iodophile reaction occurs an active inflammatory process can be assumed. It is difficult to deduce any conclusions from the reaction as to the age, nature, site etc., of the process. The iodophile substan not occ esh tubercles, and the reaction is feeb ely urulen exudates of tubercular origi ied n as ciations. The reaction could never be detected in ascitic fluids, etc., without suppuration.

Glycogen in the Prognosis of Neoplasms. PELICELLI.—The writer's study of 100 tumors of various kinds has confirmed the importance of the discovery of glycogen in a tumor as an indication of its malignancy. It is seldom found in benign tumors. He interprets it as the expression of augmented, accentuated cellular interchanges, not of degeneration. It is the more abundant, the less differentiated the elements of the neoplasm and the more rapid its growth. The glycogenic coefficient of a neoplasm is therefore an indication of its degree of malignancy and affords useful data for the prognosis. Clinical observation in every one of his cases confirmed the microscopic findings.

September 2.

Therapeutic Application of the Cell-Destroying Sera. L. LUCATELLO.—Metchnikoff and others have announced that the serum of animals treated with blood-cells from another species has a distinctly destructive action on these cells in large amounts, but that a small amount of this "cytotoxin," as they call it, stimulates the production of the cells. Like the action of alkaloids and antiseptics on fermentations, a large amount paralyzes, but a small amount induces hyperactivity. Lucatello has been testing these assertions in respect to the "cytotoxins" on four anemic children, and his experiences confirm them in every respect. Dogs were injected in the peritoneum with the blood of the patient. Their serum then acquired the property of stimulating the blood production when transferred to the patient in a subcutaneous injection of .3 to 2 c.c. The number of red corpuscles was increased and also to some extent the proportion of hemoglobin. The erythrocytes increased nearly if not quite to normal and there was slight leucocytosis. This improvement in the composition of the blood persisted for two weeks. The reaction is less pronounced in case of organic lesions with persistence of the causal process of the anemia. The influence of the cytotoxins seems to be principally cytogenic rather than hemoglobinogenic, and this independence of the two processes confirms the autonomy recently claimed for them.

September 9.

Curative Value of Tuberculosis Antitoxin. S. MIRCOLI.—Mircoli tabulates the results of this treatment in 2899 tuberculous patients, mentioning the results on the bacilli, the local lesions and the weight. He classifies the cases as circumscribed apyretic, circumscribed febrile and diffuse tuberculous bronchitis with and without microbian associations, and bronchopulmonitis with cavities. Out of 250 circumscribed apyretic patients, 95 were cured, 110 improved, 30 remained stationary and 35 grew worse. In circumscribed febrile patients, 168 out of 938 were cured, 511 improved, 163 remained stationary and 96 grew worse. Out of 332 patients with diffuse tubercular bronchopulmonitis with microbian associations, 31 were cured, 142 improved, 98 remained stationary and 61 grew worse. In diffuse tubercular bronchitis without microbian associations, 91 out of 665 patients were cured, 301 improved, 166 remained stationary and 106 grew worse. Out of the 712 patients with bronchopulmonitis with cavities, 39 were cured, 281 improved, 102 remained stationary and 240 grew worse. The improvement obtained with anti-toxin treatment is usually permanent. It seems as if the organism, once assisted to effectively defend itself, is able to continue the struggle successfully for years afterward alone. The antitoxin does not act on pyogenic associations nor in cases in which the system is unable to respond to the stimulus of the antitoxin. The aid of hygienic and dietetic measures is also indispensable. The best results were attained with 1 c.c. injected on alternate days. The antitoxin not only neutralizes the toxins, but stimulates the production of "alexins." Its power is shown by examining the blood of patients before and after treatment. The serum of a normal person has a toxic power and also a specific antitoxic power on the tuberculosis toxins to a certain extent. In a tuberculous subject, the former property is above normal, while the latter is nearly if not entirely absent. This condition tends to enhance the effect of the tuberculosis toxins in the system. A month or so after treatment with antitoxin both properties are the same as in a normal subject. This artificially-induced antitoxic power must be due to the active participation of the organism as the potential must be hundreds of times greater than the small amount of antitoxin actually injected. Experimental tests show that the antitoxin also has a direct action on the bacilli, inhibiting their growth and virulence. None of the bacilli develop or produce infection after being kept in antitoxin for twenty days *in vitro*. Tuberculosis intoxication may be conquered without medication, but when the physician is not positively sure that a spontaneous cure is impending, he should bear in mind that nature can be aided and the intoxication conquered more rapidly and more energetically with antitoxin treatment than with any other. It is applicable to all cases and all stages. Tuberculin, on the other hand, adds to the toxins already in the organism, and may prove the last straw to upset an already tottering equilibrium. The recent research on hemolysins has confirmed Maragliano's fundamental conceptions of antitoxin treatment and the autoserotherapy it induces. Naegeli's statements are also confirmatory; he found with improved methods of post-mortem investigation that 100 per cent. of the adults examined presented evidences of tubercular lesions, and claims that every adult is tuberculous. The strong are able to transform an active lesion into a latent, inactive process, and Maragliano, by supplementing the natural resources, reenforces the weak and enables them to accomplish the same result.

St. Petersburger Medicinische Wochenschrift, August 25 and September 1.

Torsion of the Cecum on Its Axis. R. WANACH.—Scarcely fifty cases of torsion of the cecum on its axis have been published. Wanach has had occasion recently to observe two which demonstrate that an external mechanical factor is not necessary to the production of the torsion. Both patients were awakened in the night by the first indications, after retiring in apparent good health. The cecum had no mesentery in one case, but was held by cicatricial fibers proceeding from the neighborhood of an old inguinal hernia. Cases of torsion of the cecum are generally more complicated than of torsion of any other portion of the intestine. In operating, the adhesions and condition of the mesentery which favor torsion must be remedied as far as possible. One patient had evidences of copious exudate in the abdominal cavity and succumbed to septic infection the next day. Clumps of ascarides and teniæ were found in the cecum which, with the ileum, was congested.

Preservation of Cadavers With Formol. J. A. PRESNO.—The climate of Cuba during July and August affords a good test of this method of preserving cadavers, first suggested by Waldeyer and described in THE JOURNAL, xxxii, p. 1438. The formol sterilizes the tissues almost completely and abolishes the cadaveric odor, so that none clings to the hands in dissecting. The tissues are firm and elastic and do not shrivel, but retain their shape and position. The muscles lose their color, although this can be prevented to some extent by adding sodium acetate to the injecting fluid.

Cure of Traumatic Tetanus With Phenic Acid. FLAVEL WOOD.—A lad of 12 developed tetanus after running a nail into his foot, with symptoms of severe infection. Ten drops of a 10 per cent. solution of phenic acid were injected subcutaneously, and fifteen minutes later 20 drops, continuing with 30 drops every half hour all that day and night. Cannabis indica—25 mg.—was added to the solution during the day, but omitted as the pupils contracted. The second day the 10 per cent. solution of phenic acid was injected in half-dram doses every two hours. The third day the patient was able to swallow and a dram of the same solution was given in glycerin by the mouth three times a day. The odor of the phenic acid was marked in the urine. Recovery was prompt and complete. Wood believes that large doses of phenic acid in these circumstances have an antitoxic influence if the system is promptly and thoroughly saturated. The antiseptic action probably occurs chiefly in the blood.

Revista de Medicine Tropical (Havana), August.

The Anopheles in Cuba. J. Guiteras.—The larvæ of the anopheles were found abundant near Havana and Matanzas, but few specimens of the culex could be obtained. Mosquitoes grown from the larvæ proved to belong to the variety described by Grassi as the A. superpictus or the closely-allied A. pseudopictus or costalis. They all rest in the characteristic attitude mentioned by Ross, the proboscis and abdomen forming a straight line, always at an angle of about 45 degrees with the surface on which the insect is standing.

Norkiskt Medicinskt Arkiv (Stockholm), August 9.

Remote Results of Operations for Chronic Ulcer of the Stomach. J. Nicolaysen.—Two of the twenty-seven cases tabulated were operated on more than five years ago, twelve more than two years and eight nearly two years ago. Pyloroplasty was made in five and gastroenterostomy in twenty-two cases. Fifteen are in good health, including all the oldest cases, and not counting the most recent. Six have died, one from ovarian tumor and one from pulmonary tuberculosis, during the second year; four of the deaths occurred soon after operation, including one from pulmonary embolism in four days, one from an unknown cause in one month and one from pernicious anemia in four months. The ulcer had been noted in two cases for fourteen and twenty-four years, respectively. Complete restitution of motility was not attained for a time varying from four weeks to several months, depending upon the degree of the previous stenosis. A corresponding curve was also noted in the faculty of absorbing nitrogen and fat after gastroenterostomy. The blood was examined in eight cases and found normal in two; in the remainder the corpuscles increased rapidly from 3,800,000 with 60 per cent. hemoglobin before operation to 4,000,000 and 5,000,000 with 90 to 100 per cent. hemoglobin afterward. Nine patients with pain and hematemesis were all cured, although four had brief relapses of pain or hemorrhage during the first or second year after the intervention, and one required gastroenterostomy to supplement the previous pyloroplastic operation.

New Patents.

Patents of interest to physicians, etc., Sept. 4 to 11:
657,328. Syringe. Wm. P. Allen, Chicago.
657,279. Bed-pan. Rosa Blank, Vienna, Austria.
657,402. Inhaler. *Peter T. Donovan, New York City.*
657,404. Hernial truss. George Fancher, Greenwich, Ohio.
657,426. Antiseptic broom. Oscar S. Kulman, Savannah, Ga.
657,440. Aspirator. Wm. J. McCaw, Providence, R. I.
657,183. Eye-protector. Edward G. Stevens, New York City.
657,866. Inhaler. Wm. H. Fike, Iberia, Mo.
657,819. Bed-pan. Harriet D. Goodrich, Augusta, Ga.
657,658. Lung tester and developer. Israel Hogeland, Chicago.
657,708. Instrument case. Gustave Rehmann, Newark, N. J.
657,578. Fountain syringe or other cap. George H. F. Schrader, New York City.
657,710. Atomizer. Emmet L. Smith, Chicago.
657,582. Combined undershirt and suspensory bandage. Frank W. Wright, Wichita, Kan.
33,189. Design, atomizer casing. Henry C. Thomsen, Hamburg, Pa.

Change of Address.

W. S. Anderson, Holly Springs, Miss., to Masonic Temple, Memphis, Tenn.
E. S. Albee, Oshkosh, Wis., to 915 Walnut St., Kansas City, Mo.
D. S. Adams, 905 20th St., Rock Island, to 404 N. Lafayette St., Macomb, Ill.

Queries and Minor Notes.

MEDICAL PRACTICE LAWS.

Farmington, Ia., Sept. 12, 1900.

To the Editor:—Can you inform me whether a physician can practice medicine and surgery in Oklahoma simply by registering, or is there a state board examination? C. C. C.

Ans.—The requirements in Oklahoma are graduation from a reputable medical college, good habits and moral character. Lacking a recognized diploma, the passing of an examination and evidence of five years' practice is necessary.

DEFINITION OF INSANITY.

Cambridge, Mass., Sept. 13, 1900.

To the Editor:—Will you kindly inform me as to the number and name of the medical journal which contains the paper by Dr. Hughes referred to in the enclosed clipping from The Journal?

Insanity Defined.—Hughes reviews some of the attempts to produce a satisfactory definition of insanity and offers the following as his contribution to the total. He says: "We need never be at sea before any court, before any jurist, in giving our views of insanity as a disease primarily or secondarily involving the brain of the individual so as to produce in him a change in the natural habits of thought, feeling or action—a change of his normal, natural mental expression by which and by reason of the disease underlying all, he is placed out of harmony with his surroundings, with his natural self or with his normal family type of mind." L. B. B.

Ans.—The above definition is contained in an article by Dr. C. H. Hughes, published in the *Alienist and Neurologist* for April, 1899, p. 170.

TREATMENT OF EPILEPSY.

Norfolk, Va., Sept. 17, 1900.

To the Editor:—On p. 719 of The Journal, under article "Treatment of Epilepsy," it says: "Flechsig's method [illegible] ied." Will you please let me know what "Flechsig's met[illegible] have a case on hand and wish to try it.

Ans.—Flechsig's method consists in giving [illegible] ¼ *gr. or less three times a day, and gradually in-*

solution and it is more convenient to make in quantity in this proportion. He takes 3 or 4 c.c. of the eosin solution and adds to it the methylene-blue solution drop by drop until the red color has just completely disappeared. I have found it more satisfactory to keep the two solutions in burettes, as is done by Bastianelli and Bignami. Having made up a liter or more of the separate solutions a few experiments will show the exact proportions of each which gives the best result, and thereafter the exact amounts can be easily measured out from the burettes. The two solutions should be mixed just before use in a covered staining dish with a concave bottom. The specimen is to be left in the stain for from three to twenty-four hours. A scum which forms on the surface of the stain should be removed carefully with a piece of filter paper, just before placing the specimen in it and again just before taking it out. The use of this method requires a certain amount of practice at the beginning, but it gives such wonderful pictures that it is well worth the trouble taken. The red corpuscles take a dark-red color and the nuclei of the leucocytes and of the nucleated red corpuscles take a deep carmine-violet. The protoplasm of the malarial parasite stains blue. The nucleus of the malarial parasite is seen to be made up of a peripheral unstained or achromatic portion and a central mass or cluster stained a deep carmine-violet, which is chromatin and is sometimes spoken of as the nucleolus.

We will now consider the different varieties of the malarial parasites as they appear at the various stages in their cycle of development.

Tertian Parasite.—The young tertian parasite when it has just entered the red corpuscle is nearly spherical or sometimes apparently ring-shaped. It has a dense rounded mass of chromatin surrounded by a thin peripheral achromatic zone. The parasite grows slowly at first, the protoplasm shows more and more irregularities in shape as ameboid movements become more active, but indications of the ring shape are often seen until the parasite nearly fills the corpuscle. After several hours pigment begins to appear in fine granules, which look brownish in color, probably on account of their minuteness. The pigment increases in amount and becomes coarser and apparently blacker. It is scattered throughout the protoplasm until near the time for segmentation, when it shows a tendency to be pushed to the periphery. The red corpuscle becomes progressively larger and paler throughout the cycle. The protoplasm of the parasite and the achromatic portion of the nucleus increase in size slowly for the first half of the cycle and more rapidly after that until near the time of segmentation. The chromatic portion of the nucleus remains unchanged for eight or ten hours, and then begins to break up into granules, which becomes finer and finer until they are invisible just before the process of segmentation begins. At this period, which is short in duration, no nucleus can be made out, but very soon fine granules of chromatin can be seen arranged in clusters and strands throughout the protoplasm. More or less pale areas can be seen in the protoplasm, but they seem to have no relation to the chromatin and it is difficult to say whether or not they represent the achromatic portion of the nucleus. The chromatin granules soon show a tendency to become aggregated in masses, at first about five or six in number. The chromatin then gradually loses its granular appearance and becomes arranged in sixteen or eighteen dense homogeneous masses, each surrounded by an achromatic zone and having a mass of protoplasm surrounding it or lying close to the side of it. The spaces between the separate segments become more and more evident and the pigment being left out collects in one or two masses near the center. The red corpuscle now ruptures and disappears and the new-formed segment is ready to begin an independent existence in some new red corpuscle as host.

Quartan Parasite.—The young quartan parasite, like the tertian, is made up of nucleus and protoplasm. The nucleus has the peripheral achromatic portion with chromatin in the center, but the chromatin is not in a solid rounded homogeneous mass as in the tertian, but is more or less irregular and often can be seen to be made up of separate granules. As the parasite grows the protoplasm and achromatic portion of the nucleus increase in size, the protoplasm showing fewer irregularities in shape than in the tertian. It is usually oval, but often stretches from one side of the corpuscle to the other like a band. The chromatin disintegrates more rapidly than in the tertian, and during a long part of the cycle is seen only as a cluster of dust-like granules. The containing corpuscle diminishes in size and stains more deeply with the eosin. The pigment is usually, but not always, coarse when it first appears, and it shows a tendency from the first to seek the periphery. The chromatin reappears, before segmentation, scattered through the protoplasm, and finally becomes aggregated in eight or ten masses, which are usually not so rounded and dense as in the tertian form.

Estivo-Autumnal Parasite.—Two different parasites have been described in the estivo-autumnal fevers, one having a cycle of twenty-four hours and the other of forty-eight hours. I have not been fortunate enough to see any case corresponding to the twenty-four hour type, so these observations refer only to the so-called malignant tertian fever. The young parasite is somewhat smaller than the young tertian or quartan parasite. The chromatin is less in amount and often becomes arranged in two small masses or a delicate strand. The rest of the cycle must be studied in material derived from the spleen by tappings during life or from the spleen or bone-marrow obtained at autopsy. The chromatin gradually disintegrates and reappears at segmentation as in the other forms. The number of segments varies from ten to twenty, or more. The chromatin appears in the segments in small round masses with a relatively small amount of protoplasm. Even at full growth the parasite does not more than one-third fill the corpuscle.

The changes hitherto described have been those seen in the sporulating generation, the mode of reproduction serving to propagate the species in the body of a single host. We will now consider the changes that take place in the sexual generation, the form of reproduction for the extension of the species to the body of a new host. This process can be best studied in estivo-autumnal fever, in which the gametes, or individuals capable of sexual multiplication, are often very numerous. They are the well-known crescentic bodies, and they can be divided into two classes according to the arrangement of the nucleus. In one the chromatin is in fine granules situated in a round, clear space at one end of the central clump of pigment. The pigment sometimes partially or completely surrounds the nucleus, and this is the type which, in the fresh blood, can be seen with the pigment in a ring. In the other type of crescent the chromatin is scattered among the pigment granules. The central portion of the crescent takes the blue protoplasmic stain more faintly than do the arms of the crescent. When the blood is taken into the stomach of the mosquito, interesting changes take place in the crescents. The same changes take place when the blood is left a short time under a cover-slip and they may be studied by leaving the thin film of blood between two cover-slips protected from evaporation in a small closed chamber. After a longer or a shorter time the cover-slips are pulled apart and the blood allowed to dry. A series may be made in this way by leaving the cover-slips in contact for from five minutes to an hour. Very soon after the blood is drawn the crescents become spherical, and here again two different forms are found. One form is small, about half the size of a red corpuscle, perfectly spherical, and has pigment scattered throughout. It has at first an irregular mass of chromatin in the center, which later becomes arranged in four or five rounded masses near the periphery. From these masses develop the motile flagella. Each flagellum is made up of a central thread of chromatin, which often has a nodular mass at the distal end or somewhere along its course. Sometimes a blue-staining envelope of protoplasm can be seen. The flagella break loose from the central mass, leaving nothing but a little protoplasm and the pigment. The other form of spherical body is three or four times as large as the first and is usually not perfectly spherical, often having a somewhat triangular shape. The chromatin is in a single large mass surrounded by a clear zone and situated near the periphery. The pigment is arranged in a more or less perfect circle, which surrounds the nucleus. These bodies never give out flagella, and they probably represent the female or macrogametes. The flagellating body represents the male, and is called the microgametocyte. I have not been able to observe the actual penetration of the flagellum or microgamete into the macrogamete, but this has been seen by McCallum. Crows are often infected with halteridium, a parasite resembling that of malaria. The blood is sometimes crowded with the parasites and the process of fertilization can be easily observed. The fertilized female is an actively motile body, shaped like a long, narrow pear, often having a small rounded appendage at the blunt end, which contains the pigment. The nucleus is situated near the center, and is made up of an irregular mass of chromatin without any achromatic portion. The process of sexual reproduction in the tertian form is similar to that in the estivo-autumnal. The gametes in blood which has just been drawn are large intracorpuscular bodies, having a large nucleus composed of fine chromatin granules surrounded by an achromatic zone. They soon become extracorpuscular, and after fifteen or twenty minutes the microgametocytes flagellate like those of the estivo-autumnal parasite. The structure of the macrogametes and microgametes differs in no respect from that already described for the estivo-autumnal parasite.

To obtain material for the study of tissues in the malarial fevers, the autopsy should be made as soon after death as possible. The tissues may be fixed in Zenker's fluid or formalin. Alum-cochineal and borax-carmin are satisfactory stains, but I have obtained my best results by leaving the sections for three days in Ehrlich's eosin-hematoxylin mixture. Unfortunately all efforts to apply the Romanowsky stains to the study of sections have resulted in failure. Much information can be obtained from cover-glass smears of fresh tissue, especially of the spleen and bone-marrow. The smears are fixed and stained like blood preparations.

The changes in the organs may be classed as those occurring in each acute attack and those resulting from repeated acute attacks. The most marked changes are found in the spleen, liver, bone-marrow, brain, and alimentary canal. In the acute attacks the spleen is enlarged owing to hyperemia and the presence in the dilated vessels of the pulp, of free pigment, parasite-containing red corpuscles, and phagocytes. The pigment may be in fine granules, but is mostly in large rounded clumps left after segmentation. The polynuclear leucocytes contain pigment and more rarely broken-down parasites. There are many macrophages or large phagocytic cells, which are usually mononuclear and contain non-infected red corpuscles, fragmented, brassy, and parasite-containing red corpuscles, free parasites intact, and broken-down, pigment in blocks and granules, and leucocytes which sometimes show signs of degeneration. On the other hand, the nucleus of the macrophage often shows by poor staining and fragmentation that it is undergoing degeneration. The red blood-corpuscle carrying cells may be increased in number. The pulp cells may be swollen and contain parasites, pigment, infected and non-infected red cells and mononuclear leucocytes. The endothelial cells of the blood-vessels are phagocytic and often contain pigment, parasites and changed red blood-cells. There may be areas of necrosis, often showing an invasion of leucocytes; capillary thrombosis may be associated with these areas of necrosis. The parasites found in the spleen may be at all stages of development, but the segmenting forms are particularly found here, especially in the estivo-autumnal variety. The chronic malarial spleen may reach an enormous size, caused by the acute process repeated many times. The dilatation of the vessels leads to the formation of venous lacunæ. The necrosis of portions of the pulp is followed by hyperplasia of the surrounding tissue in an effort at repair. The pigment is partly deposited in the perivascular tissue, from which it is removed by the lymphatics, leaving a thickening of the perivascular connective tissue.

The liver in an acute attack shows an accumulation in the capillaries of phagocytes brought from the spleen. They are leucocytes and macrophages containing red cells, parasites and pigment. The endothelial cells of the liver capillaries are phagocytic and become swollen in places, and by thus obstructing the blood-current have much to do with the dilatation of the vessels of the liver, and probably also of the spleen. Kupffer's cells, lying between the capillary walls and the rows of liver cells, also take on phagocytic action. The liver cells contain yellow granular pigment, which differs chemically from the pigment in the parasites and in the large black masses in the phagocytes and tissues. It is derived from the remnants of hemoglobin left after segmentation and from a destruction of red cells, which is probably due only indirectly to the malarial parasite through the action of the poison. It gives the microchemical reactions for iron, which the true malarial pigment does not. Areas of necrosis of the liver cells can be made out, which may be due in part to capillary thrombosis, but in the main are caused by the toxic substances in the blood, and are similar to those due to the toxins of certain bacteria. As time goes on the dilatation of the capillaries persists and the pigmentation of the endothelial cells is more evident toward the periphery of the lobules. The perivascular lymph-spaces are enlarged; pigmented leucocytes and macrophages are seen outside the capillaries and there is an accumulation of free pigment in the connective tissue. Necrosis of hepatic cells has advanced. Still later, the pigment is more markedly accumulated at the periphery of the lobules. In the n[illegible]tic areas there is a regeneration [illegible]ver tis new cells being arranged in cords along the necrosed cells. The pigmentation next becomes exclusively perilobular. There is irregularity in the size of the lobules, owing to the atrophy of some and the enlargement of others due to the formation of new liver cells. Finally there is a gradual diminution of the pigment, leaving dilatation of the vessels and a moderate hyperplasia of the perivascular connective tissue. Whether or not a true atrophic cirrhosis can be caused by malaria is not yet settled. Certainly it is not so frequent as was once supposed, and cirrhosis of the liver is not especially common in malarious regions, but from the analogy one would suppose that the areas of necrosis might well lead to cirrhotic changes, as has been shown by Flexner to be the case after similar necroses caused by bacterial toxins.

The red bone-marrow contains parasites in all stages of development in red cells and in macrophages. In the estivo-autumnal form crescents perfect and in process of formation are present in large number. These embryo crescents are sometimes also found in the spleen, but it is probable that the manufacture of crescents takes place for the most part in the marrow. In the early stages they are probably indistinguishable from the ordinary sporulating forms, but when the latter have about one-third filled the corpuscle they undergo segmentation. The young crescent, on the other hand, continues to grow until it has nearly filled the corpuscle, the chromatin remaining in fine granules. It preserves a spherical shape for some time and then gradually assumes the characteristic semilunar form.

In the lungs numerous pigmented phagocytic cells can be found in the capillaries, which are somewhat smaller than the macrophages seen in the spleen and liver.

An important characteristic of the estivo-autumnal fevers is the unequal distribution of the parasites in the different organs of the body. Often many of the capillaries of the brain are found crowded with segmenting parasites, and it is probable that the coma, convulsions, aphasia and sudden death in these cases are caused by the mechanical presence of these accumulations obstructing the blood-current in the capillaries. Small hemorrhages are sometimes observed. Another seat of localization is the stomach and intestines, where the capillaries of the mucous membrane may be filled with parasites, and areas of necrosis result. These are the "algid" cases, presenting a clinical picture resembling that of cholera.

Technique of Alimentary Rectal Injections.—Boas mentioned at the International Medical Congress that he had found a permanent sound of great assistance in feeding by the rectum. The fluid is injected a drop at a time and as much as 500 c.c. of milk can be given in this way at one "meal," administering thus 1.5 to 2 liters of milk during the twenty-four hours. He warns, however, that the prolonged use of alimentary injections of any kind is liable to lead to serious syncope, and consequently they should only be applied when constant surveillance is possible.

WHAT AMOUNT OF VISUAL DEFECT SHOULD DISQUALIFY IN RAILROAD SERVICE?

FRANK ALLPORT, M.D.
Professor Ophthalmology and Otology in Northwestern University Woman's Medical School; Professor Ophthalmology in Chicago Policlinic; Oculist and Aurist to St. Luke's, St. Joseph's and Wesley Hospitals, etc.
CHICAGO.

The title of this paper constitutes one of the unsettled points connected with the subject of the ocular and aural requirements of transportation employees. Considering the absolute lack of any such requirements whatsoever, obtaining in transportation circles, only a few years ago, it is quite surprising that so much progress has been made along these lines up to the present time. Only a few years ago, the quality of an engineer's eyes and ears was never brought into question, while now the importance of the health of these organs is a settled and incontrovertible fact. The cause of this revolution of sentiment is due to the persistent efforts of ophthalmologists, aurists and conscientious and capable railway surgeons. It must be admitted, however, that honest and sincere railroad officials have quite generally been reasonably quick to grasp the importance of the subject, and to realize the enormity of their own responsibility, in entrusting human lives, and property, to the keeping of employees physically incapable of piloting trains through hazardous situations. Besides this, the financial element has not been without its impression on the minds of railroad officials, for it soon became evident that notwithstanding the fact that ocular and aural examinations of employees entailed some additional expense, in the long run it was a distinctly economical measure, as it was much cheaper to entrust trains to men known to possess good eyes and ears than to pay for accidents, damage suits, etc., believed to have been due to defective conditions of these organs of special sense. In England, Holland, Sweden, Norway, Germany and other European countries a paternal government frames beneficent laws concerning ocular and aural requirements of railway employees. These requirements are not always what they should be, but nevertheless the government considers the matter of sufficient importance to regulate the subject, and that signifies much and presages better things for the future. In this country, there are still, it must be regretfully admitted, some railroads requiring no standards whatever of ocular and aural health of their employees, and whose officials dogmatically and stubbornly assert that determining examinations are unnecessary, as they know when a man has bad eyes or ears, without paying a doctor to disclose the fact. But while such officials are thus far behind the times, a very large majority of American railroads are operated under some kind of regulation and restriction, which clearly demonstrates that their managers are unable to close their eyes to the importance of the subject. These requirements are frequently most meager, unsatisfactory, unsafe and unscientific, but nevertheless they disclose an acknowledgment of the subject's importance in the minds of railway officials, and this is a victory that will expand and grow in the not distant future.

Certain points concerning eye and ear requirements for railway employees are quite well established and much time, therefore, need not be expended in their discussion. For instance, it is practically conceded by all interested parties, including even the employees them-

---

[*] Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

selves, that every one connected with the actual moving of trains should have good eyes and ears. The standards of excellence, and the means of investigation, are still under discussion, but the main fact as just presented, may be said to be settled. There is a practical unanimity of sentiment concerning color perception, and while concessions are frequently made to old employees with diminishing visual acuity, the standard of perfection regarding the color sense is maintained for all time, in all railroads paying any attention whatsoever to the subject. In order to ascertain if possible what is being done in railroad circles in matters of this nature, I have sent a letter of inquiry and a question blank to every railroad in the United States, Canada and Mexico operating over 100 miles of road. Two hundred and forty-four railroads were thus addressed, covering 205,638 miles of road. I have received replies from 64 roads, operating 90,950 miles of road, and I have tabulated these reports, and herewith present them in statistical form. It is to be regretted that all the roads did not reply, but such a fortunate result was, of course, not to be expected. Sufficient has, however, been learned to gather a reasonably good idea as to what representative railroads are doing in the way of eye and ear examinations, and I shall beg leave to briefly analyze the different points in the report.

I find that 53 out of 64 roads exact a systematic eye and ear examination of some kind. These examinations are undoubtedly bv no means ideal in many instances, but it shows an active interest in the matter, and emphasizes the fact that but few roads have the assurance to face public and professional opinion by openly avowing their non-adherence to the trend of advanced thought and ordinary caution.

As to what men are subjected to such examinations, the replies are differently couched, but it is evident that at least 50 of the roads require such examinations of all men directly engaged in moving and operating trains, and in giving and receiving signals, such as engineers, firemen, conductors, brakemen, yardmen, signalmen, switchmen, etc.

One road acknowledges not making systematic examinations, but when they are made, from any reason, subjects such men as just mentioned to the ordeal. Another road under similar circumstances confines the examinations to engineers, firemen, conductors and brakemen. One road claims to make systematic examinations, but only engineers and conductors are tested. Another road only examines engineers, conductors, brakemen and firemen.

Concerning the question as to how these examinations are made, it will be seen that they are conducted exclusively by the railway surgeons in nineteen roads. Eighteen roads entrust the tests to a railway employee, such as a division superintendent, trainmaster, etc. Under this arrangement it is believed that only doubtful cases are sent to the railway surgeon. Upon six roads, doubtful cases are sent to an eye and ear surgeon. Nine roads entrust the whole matter to a regularly employed eye and ear surgeon, and three roads first have the men examined by the railway surgeon, who then sends doubtful cases to the eye and ear surgeon. In three roads, the examinations are all made by surgeons of railway relief associations.

Regarding regular systematic re-examinations there is great diversity of action. One re-examines every six months, four every year, fourteen every two years, four every three years, and two every four years. Eight re-examine whenever it seems advisable, as after a severe illness or injury, or after a railway accident, or when certain incidents bring into question the reliability of the eyes or ears of an employee. One road requires re-examinations merely at times of promotion, and another when a man arrives at the age of 50 years.

As to the standard required from examined men, there is also much diversity of opinion. Upon twenty-three roads it is claimed that perfect eyes and ears are required from new men, and that no concessions whatever are made to old employees. This statement seems rather broad and Utopian, and really hardly possible, unless old employees are constantly discharged to make place for younger and more perfect men, and the writer is unaware of any road where such practices exist, and would not approve of them if they were. A perfect standard should be required of men entering a service, but it would be unnecessarily cruel and inflexible to continually discharge old and trusted employees simply because their vision had dropped to 20/30, or had slightly impaired hearing, and whose experience and matured judgment make them extra valuable to the service. This statement, it is believed, therefore, must be unconsciously somewhat highly colored, at least it is hoped that this is the case. In sixteen roads, while perfection is required of new men, various reasonable concessions are made to old employees. On one road the following requirements are made: Engineers and firemen shall possess a vision of 20/20 in one eye and 20/30 in the other. Conductors, flagmen, brakemen and switchmen must have a vision of 20/30 in one eye and 20/40 in the other. Other employees must possess vision equaling 20/40 in both eyes. Upon the road just referred to, it was not stated whether the requirements were for new men only, or whether it is the universal and constant standard to be perpetually observed. With one road the applicant must possess eyes and ears whose functions shall equal 75 per cent. of the normal function. One road requires perfect eyes and ears for firemen. All the employees must possess vision equaling 20/20 in one eye and 20/50 in the other. Another road sets the standard of vision at 20/30 and declares that a whisper must be heard at twelve feet. One road requires a combined vision of 20/20, and that neither eye shall drop below 20/70. Another road requires of engineers, firemen, signal-tower men and switchmen vision of 20/20 in one eye and 20/30 in the other. All other men must have 20/30 in each eye, or 20/20 in one eye and 20/50 in the other. Upon two roads employees are retained who still possess vision equaling 20/40 in both eyes, and when the hearing is half lost in one ear, provided the other ear is perfect.

It is interesting to notice under what circumstances a man is considered an old employee by different roads. One road considers a man an old employee when he is once installed into actual service; another after he has worked one year; another after two years of service. Six roads require three years of service; eight roads five years; one road six years; six roads two years, and two roads fifteen years.

Concerning the use of glasses, when on duty, it is feared that the question has been misunderstood. I meant to ask the question as to whether glasses were permissible in actual service, when their use was necessary to bring vision up to a proper distant standard; but owing to so many roads (45) returning an affirmative reply, I fear the question was interpreted to refer to the use of glasses for reading when on duty. Seven roads, however, specifically state that old employees may wear distance glasses, if glasses will enable them to reach

Statistical Report of Eye and Ear Requirements of Railway Employes

By FRANK ALLPORT, M. D.
Of CHICAGO, ILL.

No.	Railroad.	Miles.	Are Eyes and Ears Systematically Examined.	If so, what class of employes? And do you require same standard for all classes.	Are such examinations made by an Eye and Ear Surgeon, a General Surgeon, or by some R. R. Employee?	Do you require reexaminations from time to time and if so, at what interval or under what circumstances?	Do you require perfect vision, color sense and hearing in new employees? And what concessions do you permit from a perfect standard in the case of old employes?	How long must a man work on your road before you call him an old employee?	Do you permit old employes to wear glasses when on duty?
1	Louisville Henderson & St. Louis.	188	Yes.	All classes in Transportation Department.	By General R'y Surgeon.	No.	Yes. None.	No rule.	Yes.
2	Ohio Central.	525	*Yes, but not scientifically* Men required to pick out different colored worsteds Other tests very inaccurate		By Superintendent or his agent.	No,	Yes, as before stated.	No rule.	Yes.
3	Freemont, Elkhorn & Mo. Valley.	1408	Yes.	All employes in train and yard service. Same standard for all.	General R'y Surgeon, also by Eye and Ear Surgeon.			No rule.	Yes.
4	Buffalo, Rochester & Pittsburgh.	475	Yes.	Engineers, Firemen, Conductors, Flagmen, Brakemen, Switchmen, Yardmaster, Operators, Section Foremen, Foremen of Bridge gangs, etc.	By Trainmaster.	Once a year	Engineers and Firemen must have 20/20 in one eye, 20/30 in the other. Conductors, Flagmen, Brakemen, Switchmen must have 20/30 in one eye and 20/40 in the other. All others 20/40 in both eyes.	No rule.	Yes.
5	Pittsburgh & Lake Erie.	180	Yes.	Train Dispatchers, Telegraph Operators, Conductors, Brakemen, Enginemen, Firemen, Switchmen, Crossing Watchmen and Section Foremen.	General Surgeon and approved by Company Eye and Ear Surgeon.	Every two years. Re-examination made by Company Eye and Ear Surgeon.	Yes, old employes allowed to wear glasses, if defect in vision can be corrected by them.	No rule.	Yes.
6	Hocking Valley	346	Yes	Conductors, Engineers, Brakemen, Firemen and Operators. Same standard for all above men.	General Surgeon.	Every three years.	Require Perfection in all new employes. No rule about old employes.	Fifteen years.	Yes.
7	New York, Chicago & St. Louis.	523	Yes	All who use and observe signals.	Primarily by Div. Supt, special cases by special Surgeon.	Yes, every two years, or oftener if men seem to require it.	Yes, no concessions.	Ten years.	Yes.
8	Long Island.	379	Yes	Trainmen., Enginemen, Switchmen, Towermen, Flagmen.	General Surgeon.	Every two years.	Yes.	Three years.	Yes.
9	Rock Island & Peoria	123	Yes	Engineers, Firemen, Brakemen, Baggagemen	Both.	If thought necessary.			Yes.
10	Fitchburg.	450	Yes.	All men in train service having to do with signals.	First by employee. Then by Specialist if necessary.	Every two years.	Yes, if vision can be made satisfactory by glasses, they may be used.		Yes.
11	Wabash.	2275	Yes.	Employes engaged in moving trains.	General Surgeon.	No rule.	Yes. No concessions.		Yes.
12	Grand Rapids & Indiana.	590	Yes	Engineers, Firemen, Conductors, Brakemen. Switchmen and Baggagemen	Eye and Ear Surgeon.	Every three years	Yes.		Yes.
13	Michigan Central	1662	Yes. (Eyes)	Men in engine and train service	Railroad officer.	If defect is noticed.	Yes. No Concession.		Yes.
14	Omaha, Kansas City & Eastern Ry.	315	Yes.	Engineers, Firemen, Conductors, Switchmen, Brakemen. Same standard for all. . .	Eye and Ear Surgeon,	No regular re-examination.	Yes. No concessions. In case of defect other employment is given.	One year.	Yes.
15	Central Vermont	513	No.	Men in train and yard service examined by Transportation Department officers.					
16	Florida Central & Peninsular.	940	Yes.	All men engaged in train service. Same standard for all.	Eye and Eye Surgeon.	Re-examination annually, oftener if necessary.	No concessions.		Yes.
17	Yazoo & Mississippi	969	Yes	All men engaged in train service, including train dispatchers and telegraph operators.	General Surgeon.	No regular re-examinations.	Yes. Some concessions with old employes.	Five years.	Yes.
18	Minneapolis & St. Louis.	504	No.	Engineers. Firemen. Conductors and Brakemen.	Train Master.		Yes, for new men.	No rule.	Yes.
19	Chesapeake & Ohio.	1376	No.				We require perfect vision and hearing in all employes.		Yes.
20	Rio Grande, Sierra Madre & Pacific.	160	Yes.	All whose duties require them to use signals, flags, lights, etc.	By General Surgeon and one other appointed by Government.	No.	No exceptions.	Three years.	
21	Cincinnati New Orleans & Texas Pacific	336	Yes.	Conductors, Engineers Firemen, Brakemen and Operators All in same manner.	Employe	We do, every three years	Require perfect vision, color sense and hearing in new employes. Color test made by requiring men to pick out different colors.		Yes.
22	Chicago, Terminal Transfer.	208	Yes.	Train and Enginemen	By Supt. or Train Master.	Not unless we have reason to believe employes eyesight or hearing is failing.	Require men to be able to distinguish colors of our signals and to have good hearing.		Yes.
23	Wheeling & Lake Erie.	462	Yes	Engineers, Firemen, Conductors, Brakemen, Yard Masters, Station Agents, Telegraph Operators. All persons in any way concerned in the movement of trains or handling of signals. Same standard for all classes.	By Division Superintendent.	Every two years.	An average of 75% is required. When applicant stands less than 50% in sight, color sense or hearing, though he be perfect in the other two he is rejected.	Ten years.	Yes.
24	Ft. Worth & Rio Grande.	142	No.					Five Years.	
25	Lehigh Valley	1402	Yes.	All train and yard employes.	First by instructed employe Doubtful cases by Chief General Surgeon.	Re-examinations at stated intervals required for heavy users of tobacco or for progressive ocular diseases.	New employes must be perfect. Old employes are passed on 20/20 one eye, 20/40 in other, with good range and field.	About ten years.	Yes.
26	Ohio Southern	215	Yes.	All engaged in giving or interpreting signals.	By Railway Employe.	General re-examination every two years.	New men required to be perfect. Some concessions to old employes.	Ten years.	Yes.
27	Baltimore & Ohio.	2205	Yes.	Same standard for all engaged in giving or interpreting signals.	By Medical Examiner of Relief Department.	Every two years in *Ohio*, in other states, as indicated by Gen. Mgr.	Perfect eyes and ears of Firemen, when entering service. All other train men must have normal vision in one eye and 20-30 in the other. In case of old employes, each case is considered on its merits.	No rule.	Not in case of trainmen.
28	Philadelphia & Reading & Atlantic City.	1080	Yes in certain classes.	Enginemen, Firemen, Crossing Watchmen, Yard Corps, Brakemen, Yard Masters, Conductors, Train Baggagemen, Car Runners, Car Couplers and Engine Wipers. There are two standards for acuteness of vision, otherwise the same standard	By Relief Association.	Every three years.	(a) Yes, except that two standards for acuteness of vision are required, according to [illegible]	Five years.	Yes.
29	Santa Fe Pacific.	818	Yes.	All engine, train and yardmen, crossing watchmen and signal towermen must be examined. Same standard for all.	Eye and Ear Surgeon.	*Re examinations every two years.*	1st—Yes. 2nd—Certain concessions are made to old employes where there is no danger.	*No Rule*	Yes.
30	Chicago and [illegible]	648	Yes.	Engineers, Firemen and Trainmen.	R. R. Employe.	Yes once a year.	Require Perfection.	Five years.	No not on train or engine service.
31	Cincinnati & Northern.	402	Yes.	Engineers and Conductors.	Eye and Ear Surgeon.	Every two years.	Perfection required.	Five Years.	Yes.
32	[illegible]	1156	No.					Fifteen years.	Yes.
33	Atlantic Valdosta and Western.	114	No, new road, but owing to your circular will have examinations made at once						
34	Cincinnati Portsmouth & Virginia	215	No.					Three years.	Yes.
35	Atlantic Coast Line.	1716	Yes.	Engineers, Conductors, Brakemen and all employes using flag and lantern signals. All employes of transportation service.	Medical Examiner and Relief Department.	Not yet, but probably will soon.	Vision must equal 20/30. Hearing must equal 12 feet for whispered voice.	No rule.	
36	Mobile & Ohio.	[illegible]	Yes.	All engaged in transportation service and giving and interpreting signals. Station agents, Telegraph Operators, Station Baggagemen and Crossing Flagmen. Will be accepted with 20-40 of vision in one eye and with 20-20 in the other, or with 20-30 of vision in each eye.	Railway Surgeon.		Yes, for new employes.		
37	Denver & Rio Grande	1666	Yes.	All men engaged in train service and who have to do with giving or interpreting signals. Same standard for all.	Usually by the Eye and Ear Surgeon. Never by a non-medical man.	Re-examination on promotion and where suspicion of sight or hearing is aroused.	Perfect eyes and ears required in both old and new employes.	Not considered.	Yes, in special cases.
38	Minneapolis St. Paul and [illegible]	1253	Yes.	Same standard for all employes and all are required to be examined.	On entering service by Railway Surgeon. On promotion to an engine by Eye and Ear Surgeon.	Once in two years by Eye and Ear Surgeon.	Yes. Not much concession to old employes and none when on engine.	Seven to ten years.	Not on engine nor train service.
39	Mexican International.	744	Yes.	Conductors, Brakemen, Engineers and Firemen.	Railway Surgeon.	No.	Require good eyes and ears and make no concessions.	Five years.	Only for reading.

40	Grand Trunk	4186	Yes after May 1, 1900	Enginemen and all trainmen. Same standard for all.	General Surgeon.	Not determined.	Not determined.	Ten years.	
41	Southern Railway.	6415	Yes.	Those employed on train service.	Railway employe. In case of doubt the Railway Surgeon.	No.	Perfection in all.	No Rule.	
42	Galveston, Harrisburg, San Antonio.	1064	Yes.	Same standard for all men connected with operating department.	Railway Surgeon.	Not Yet.	Yes.	Two or three years.	Yes.
43	Texas & New Orleans.	343	Yes.	Same standard for all men connected with operating department.	Railway Surgeon.	Not yet.	Yes.	Two or three years.	Yes.
44	New York, Texas, & Mexican & Gulf Western, Texas & Pacific	225	Yes.	Same standard for all men connected with operating department,	Railway Surgeon.	Not yet.	Yes.	Two or three years.	Yes.
45	Norfolk & Western.	1551	Yes.	All connected with train service. Same standard for all.	First by Division Supt. These reports are sent to Company Surgeon. Defectives are then sent to Eye and Ear Surgeon.	Yes, every two years, and oftener if necessary.	Require perfection. Some concessions made to old employes, especially those who have been injured in the Company's service.	No rule.	Yes, except firemen or brakemen.
46	Canadian Pacific.	7251	No.				Do not employ or continue in service any man known to have defective eyes or ears.	No rule.	Yes.
47	Cleveland, Cincinnati, Chicago & St. Louis.	2300	Yes.	All connected with train service. Requirements vary in accordance with responsibility of duties.	By railway employe. Reports sent to Eye and Ear Surgeon Doubtful cases are sent to Eye and Ear Surgeon.	Every two years and when deemed necessary.	Standard varies in accordance with the responsibilities of duties.		Yes.
48	Chicago & Northwestern	5096	Yes.	All engaged in operating trains or in giving or interpreting signals. Requirements vary in accordance with responsibilities.	By Railway Surgeon.	No.	Require perfection on entering service. Some concessions are made to old employes	No Rule	Yes.
49	Chicago, Rock Island & Pacific.	3562	Yes.	All engaged in train service and in giving and interpreting signals. Same standard for all.	Usually by Eye and Ear Surgeon,	Every four years and when deemed necessary.	Require combined vision of 20-20. Neither eye must have a vision of less than 20-70 which must be reached without glasses. Color sense and hearing must be perfect No concessions		No, except for reading.
50	Chicago, Rock Island & Texas.	121	Yes.	All engaged in train services and in giving and interpreting signals. Same standard for all.	Usually by Eye and Ear Surgeon.	Every four years and when deemed necessary.	Require combined vision of 20-20. Neither eye must have a vision of less than 20-70, which must be reached without glasses Color sense and hearing must be perfect No concessions		No, except for reading.
51	El Paso & North-Eastern Railway.	204	No.						
52	Vandalia Line	507	Yes.	All engaged in train service and in giving and interpreting signals. Same standard for all.	By employe. If defect is found, man is sent to Eye and Ear Surgeon.	Once a year.	Perfect eyes and ears in new men Old employes may wear glasses if defect can be thus overcome	No rule.	Yes.
53	Chicago and Great Western.	1024	Yes.	*Engine and train men and yard men.*	*Railway employe. Doubtful cases sent to Company Surgeon or Oculist.*	*Yes, as men in the service get to about fifty years of age.*	*Perfect in new men. 70% in old employes.*	Six or seven years	No.
54	Mexican Central	1955	Yes.	All in train service. Same standard.	General Surgeon	Yes, when defects are suspected.	Require perfection.	No Rule.	No.
55	Oregon Short Line.	1476	Yes.	All men in operating Department.	Eye and Ear Surgeon.	Every two years.	Yes, concessions made to old employes, where such concessions are not dangerous	Two years.	
56	Southern Pacific.	5783	Yes.	All train and station men. Practically same standard for all.	General Surgeon	No.	For Engineers, Firemen Signal tower men Switchmen 20-20 in one eye and 20-30 in the other is required for all others 20-30 in each eye or 20-50 with one eye if the other is 20-20	All actual employes.	Yes.
57	Pennsylvania Lines West of Pittsburg.	2672	Yes.	All having to do with signals.	Railway employe, supervised by Company Oculist.	Every two years.	New employes must be perfect. Old employes allowed some concessions according to position held.		Yes.
58	Colorado & Puget Sound R. R., Pacific Coast R. R., Port Townsend R. R., and Seattle & Northern R. R.	210	Yes.	Conductors, Brakemen, Yardmen, *Engineers and Firemen.*	By Company General Surgeon.	Re-examinations not re*quired unless circum*stances require them.	Perfection for new men entering *train, yard or engine service.*	Five years.	Yes.
59	New York, Philadelphia & Norfolk.	112	No.		Nothing but a general superficial examination is made such as by a careful personal scrutiny.	No.	As before stated.	No rule.	Yes.
60	Atchison, Topeka & Santa Fe.	4736	Yes.	Men who give and receive signals.	Always by a surgeon, sometimes by Eye and Ear Surgeon, sometimes by local Surgeon.	If examination is not satisfactory, the man may be ordered to report again in six months.	Perfect for red and green. One eye must be perfect and the other not less than two-thirds.		Yes, when reading.
61	Wisconsin Central.	858	Yes.	All classes of employes connected with train service.	By General Surgeon	Every six months, or when deemed necessary.	Yes, as to new employes. If old employes can have sight made normal by use of glasses we allow it.	No rule.	Yes.
62	Great Northern	4969	Yes.	All employes in train service and Section Formen are required to pass visual and aural examinations Operators examined on eyesight Same standard for all.	By employe and submitted to Surgeon for approval	No, unless there are indications of defect.	Yes, old employes permitted to wear glasses if vision can be made *normal by their use.*	Five years.	Yes, as before given.
63	Illinois Central.	3780	Yes.	All engaged in operating trains or in giving or interpreting signals. Requirements vary in accordance with responsibilities.	By Railway Surgeon.	No.	Require perfection on entering service Some concessions are made to old employes.	No rule	Yes.
64	Gulf, Colorado & Santa Fe	1088	Yes.	All Train and Enginemen, Yardmen, Agents and operators.	By Railway Surgeon	Only when some defect is suspected.	Perfection required in new men. In old employes, vision if 20-40 passes. Perfect hearing in one ear and ½ in the other.	When once in service	Yes.
Total Miles		90,950							

the proper standard. My personal views on this matter are materially changing by experience and observation. I am fast coming to believe that the standard of distant vision by a railway employee actively engaged in operating a train should be reached without glasses. It certainly may well be questioned whether dirty, foggy and smoky glasses are safe adjuncts to vision before the eyes of an engineer or fireman, who peers into an uncertain atmosphere, with a train going at the rate of fifty miles an hour. The writer knows of instances where glasses are laid aside under such circumstances, the employee feeling that while his own vision is poor, it is better unaided than when encumbered by glasses such as have just been described. The question of glasses breaking or being mislaid during the progress of a trip must not be forgotten, and it certainly is no argument in favor of such a train employee wearing glasses.

One road says that glasses on a train may be used only when reading. This is rather an unnecessary remark, as it surely is a necessity to allow men to use reading glasses on trains, as most orders come in written or printed form, and must often be read by a man of 45 or 50 years of age or more, who can not possibly read without glasses. Seven roads specifically state that they do not allow distance glasses during train duty when such glasses are necessary to bring vision up to the proper standard.

Thus it will be seen that on all points bearing on the visual and aural capacity of railroad employees there is much diversity of opinion on the part of the employer and the employed, and also on the part of railway surgeons and eye and ear surgeons themselves. This is unfortunate, and precludes the probability of meeting on mutual ground, and formulating rules that shall be safe, and yet not extreme nor Quixotic.

I beg leave to submit some practical suggestions along these lines that appear to me to be just and equitable. If members of the Section entertain different views, it is to be hoped they will be mentioned, and that a discussion will enable the Section to formulate principles regulating this matter, that will be a true reflection of the opinion of a representative body of eye and ear surgeons, and which it is hoped will have some influence in molding the regulations on this important subject.

1. The essential principle to be advocated is that railroad corporations shall require a scientific and correct entrance examination of the eyes and ears of those employees at all to be concerned with the active operating of trains, or in giving or receiving signals.

2. Such examinations are best made by regularly appointed eye and ear surgeons. But if such a course is not deemed advisable, the company surgeon, aided by his medical assistants, may conduct them, with the understanding that all doubtful cases shall be sent to a regularly appointed eye and ear surgeon. Non-medical men shall never conduct the examinations.

3. There shall be two general standards of visual and aural requirements, viz., those for new men hoping to enter the service, and to be actively engaged in the operation of trains, and in giving and receiving signals, and secondly, those men engaged in similar work, who have been uninterruptedly in a company's service for five years, and who have, therefore, a right to be called old employees.

4. New men shall be required to possess perfect color sense. They shall also have a vision of 20/20 in each eye, without glasses, and have healthy eyes, and not over two diopters of hypermetropia. They shall also hear the whispered voice at 20 feet in a quiet room, and have healthy ears.

5. For purposes of graduated requirements old employees shall be subdivided into two classes as follows:

Class A.—Engineers, firemen, conductors, brakemen, switchmen, signalmen, switch tenders, and engine dispatchers.

Class B.—Track foremen, bridge foremen, crossing flagmen, bridge tenders, gatemen, train baggagemen, telegraph operators, station agents, and station baggagemen.

Employees enumerated in Class A shall not be retained in such positions if vision sinks below 20/30 in one eye and 20/40 in the other, or if the whispered voice cannot be heard in a quiet room at 15 feet by one ear and 10 feet by the other. Employees enumerated in Class B shall not be retained in such positions if vision sinks below 20/40 in one eye and 20/50 in the other, or if the whispered voice can not be heard in a quiet room at 10 feet by both ears. Employees, and especially engineers and firemen enumerated in Class A, must reach the visual standard without glasses and will not be allowed to wear distance glasses when on duty. Employees enumerated in Class B may reach the visual standard with glasses, and will be allowed to wear glasses when on duty, and will be required to do so if the wearing of glasses is necessary to bring vision up to the proper standard. All the employees shall have perfect color sense.

6. Re-examinations shall be made of all men every three years, and after a severe illness, or accident, or any occurrence which seems to cast doubt on the visual or aural capacity of an individual. Re-examinations shall also be made more frequently on men known to be excessive users of tobacco, or to be suffering from syphilis, albuminuria, diabetes, or acute or chronic eye and ear disease. Men shall always be examined before promotion.

7. Men known to be excessive users of liquors shall not receive employment.

It would seem as if these rules were sufficiently comprehensive and liberal to be adopted by any railroad; at the same time they are believed to be sufficiently stringent to exclude dangerous eyes and ears from the service. They will, of course, exclude a certain proportion of old employees from their accustomed occupation, but this is of small moment compared to hazarding the lives and property of the public by the retention in service of physically incompetent men. Railroads can always, if they choose, lessen the disappointment of an old employee, by transferring him to some other and less hazardous position, with a liberal salary.

I desire to emphasize what was said in Rule 2 concerning the appointment of examining eye and ear surgeons. I believe it is best that such examinations should be made directly under the supervision of eye and ear surgeons. Ophthalmology and otology have advanced with such strides that no general surgeon can keep well informed on these subjects. An examination of the color sense is by no means the simple matter that some would have us believe, and examinations for vision, the field of vision, and ocular and aural functions and diseases require the services of one especially skilled in such matters. The argument is frequently used that in large railroad systems, the work would be too ponderous for any one man. This is true, but now-a-days skilful oculists and aurists may be found in every city of a few thousand inhabitants, and appointments in different places might be made, and the work properly performed, with but little expense. However, I have no desire to draw the lines too tightly on this subject, and I believe that general satisfaction to all interested in this subject would be accomplished, if such examinations were *never made by non-professional men,* but by the general surgeon, or his medical assistants, and that an eye and ear surgeon should be appointed on each road, who should outline the details of these examinations and to whom all doubtful cases should be promptly sent.

Referring to Rule 3, that treats of perfection required in new applicants, it would seem as if there could scarcely be a doubt as to the advisability of rigid requirements for those hoping to become employees, and yet some ultrapractical railroad men and general surgeons believe that perfect eyes and ears are unnecessary requisites for such applicants. The world is full of healthy men possessing perfect eyes and ears; therefore, while a railroad is under no possible obligations to primarily employ a man, why should they not secure men of this standard, and at least start right. This is not only an act of justice to the road, which certainly possesses the right to demand the highest physical standard in an entering employee—for it is expected to make many physical concessions later on—but it is also an act of justice to the man, who enters railroad service with hopes of advancement in mind, but whose ambitions may be harshly dissipated later in life, when eyes and ears, barely sufficient to admit him to service under an inferior standard, diminish in power, until, at a crucial period in the man's life, when about to realize his hopes, these organs prove incapable of standing the required test. While, therefore, I am heartily in favor of making all possible concessions to old employees at all compatible with safety, believing that age, experience, familiarity with routes, judgment, etc., compensate to a degree for somewhat defective eyes and ears, I am positive that the standard should be perfection for those applicants hoping to enter the service of a railroad corporation for the first time.

Concerning Rule 4, and the possession of an applicant of more than two diopters of hypermetropia. This is a point that is rarely taken into consideration in initiatory examinations, and yet the suppressed hypermetropia of early manhood often plays an important rôle later in life, in the exclusion of old and trusted employees from active duty. Ophthalmologists are familiar with the fact that considerable hypermetropia may be suppressed by an active ciliary muscle during youth, and a vision of 20/20 or more be apparent during a superficial examination. But railway officials and surgeons are perhaps not so well acquainted with these data, and with the fact that in later life, with the decadence of ciliary activity, the lack of visual power becomes manifest and the use of glasses necessary to reproduce normal vision. Therefore, it would certainly seem desirable that no man should enter railway life expecting to be engaged in active transportation service, possessed of such a handicap. This point would seem to be one of the strong arguments in favor of ocular examinations being made by oculists, as one unfamiliar with such work would find the detection of latent hypermetropia rather difficult to accomplish.

Concerning Rule 5, it seems eminently proper that from an ocular and aural standpoint, employees should be divided into two classes, according to the responsibilities of their duties and their prospective occupations by promotion. An effort has been made to do this under the two classes A and B. Those old employees in Class A, owing to the importance of their positions, are never allowed to sink so low in the requirement scale as those of Class B. It certainly seems no more than just to the safety of the traveling public, that the eyesight of an engineer, fireman, conductor, etc., should not be lower than 20/30 in one eye and 20/40 in the other; that this vision should be obtained without glasses, that are objectionable for the reasons previously mentioned, and that the hearing should not be less than the perception of a whisper by one ear in a quiet room at 15 feet, and by the other at 10 feet. At the same time an old employee in Class B, such as a baggageman, telegraph operator, station agent, etc., would undoubtedly be perfectly safe with the requirements already enumerated.

Concerning the aural capacity of old employees, it seems inadvisable to make rules of excessive stringency covering this point. Very little work in transportation service is done by the voice; it is almost all done by signals, and the possession of good hearing is often a matter of no importance whatever. For instance, conversation on an active engine is practically impossible, and it is not inconceivable that a deaf engineer or fireman might be quite capable of being an efficient employee. Still, such laxity is evidently undesirable, and it is believed that the limits referred to under Rule 5 will be just to all concerned. The Railroad Commission of Germany declares unreservedly that as long as a man is capable of hearing an ordinary conversational voice, he is quite competent to work on an engine; and as engineers, firemen, etc., who work constantly amid the noise, dirt and exposure of an engine, which becomes emphasized on mountainous and tunnelled roads, are quite apt to lose their acuteness of hearing, somewhat after the manner of boiler-makers, every possible concession should be made to them.

Referring to Rule 6, and the subject of re-examinations, it may be said that if a railroad deems it at all advisable to carefully test men on entering the service, they should consider it equally necessary to enforce re-examinations at stated intervals, of which three years seems to be a fair compromise. It is unnecessary to dwell on the fact that serious eye and ear defects are liable to occur in much less time than three years, but of course some chances must necessarily be taken, and it is believed that, with enforced re-examinations every three years, and whenever through accident, illness, overuse of tobacco, promotion, etc., such re-examinations are thought advisable, reasonable safety will be assured the traveling public, as far as the eyes and ears of railway employees are concerned.

I desire to mention two practical points in testing vision for railway purposes, that are not always observed, *and that have much bearing on the subject. One is to* see that applicants and employees are tested with a considerable variety of test cards, as men become familiar with a limited number, and sometimes memorize them, and pass such knowledge on to their comrades. Another point is to have the test cards always lighted by uniform and ample illumination. For instance, I can always secure a little better vision in my private office, where the test cards are illuminated by shaded electric lights, than a railroad surgeon can in his office, where such conditions do not prevail, and have several times had my results questioned, probably on this account. Besides this, test letters are by no means of uniform size, and I believe that this element may also have considerable to do with unsatisfactory, unstable, and inharmonious results.

In closing this article, I beg leave to remind the Section of the great importance of the subject, for it has been estimated that there are in this country upward of 200,000 miles of railroad, employing about 900,000 men. In the year 1899, nearly 500,000,000 passengers were carried, and nearly 800,000,000 tons of freight. In the same year nearly 2000 employees were killed, and about 32,000 injured. Nearly 4700 passengers were killed and 6200 injured.

In the face of such facts, no apology is needed for honest and persistent efforts tending toward the uniform adoption of proper and scientific requirements from railroad employees by railroad employers.

DISCUSSION.

DR. C. H. WILLIAMS, Boston—I am sorry Dr. Allport's list does not include three of the large railroad systems where some of the most careful examinations of the vision and color-sense of employees are now being made. I refer to the Pennsylvania lines east of Pittsburg and Erie, concerning which Dr. Thomson can tell us later, the Chicago, Burlington & Quincy system and the New York, New Haven & Hartford system. For about six years, from 1889 till 1895, I was medical director of the Burlington system, and, among other duties, had charge of putting in operation the tests they are now using, and a little more than a year ago I was requested by the New Haven road to instruct their examiners and to draw up a set of rules to govern these examinations, so that I am familiar with the work which is being done on those two roads. On the Burlington system the tests are made by the physicians of their Relief Department, who have been carefully instructed in regard to the methods to be followed. *All material for the tests is furnished* by the company, to ensure uniformity, and is inspected from time to time to make certain that it is kept in good condition. The report of every examination is sent to Chicago for final approval by the medical director, which serves as a check on the thoroughness of the work, and any doubtful cases are referred to him.

On the New Haven system the examinations are made by employees selected by each division superintendent. These examiners are first tested to see if their vision, color-sense and hearing are up to standard; they are then carefully instructed by an expert in regard to the methods of making these examinations and are furnished with a set of rules to govern the tests and a set of blanks for recording the results, all these reports being sent to the office of the general superintendent for file, and any doubtful cases being referred to an expert for further tests.

On the Pennsylvania system these tests are also made by nonmedical men, and although I believe it is better, where possible, to have these examinations made by trained physicians, and to have them include not only the tests for vision, etc., but also the heart, lungs and general physical condition, especially of men applying for work; yet, when this can not be done, the vision tests can be made very satisfactorily by intelligent men selected from among the employees, provided they are properly *instructed, are furnished with suitable apparatus and rules to* govern the work, and some provision is made to refer any doubtful cases to an expert. With a well-devised sys[illegible] examination by trained employees is l[illegible] give m[illegible] ter results than when made by ph[illegible] have special training for this work, or who are not supplied with suitable apparatus for making the tests.

The instructions of the New Haven road at present provide for the following standards of acuteness of vision: "Class A, enginemen, firemen, towermen and drawer tenders, on entering the service or promotion, 20/20 in each eye without glasses. Class B, conductors, brakemen, switchmen and others who are required to pass a visual test, on entering the service or promotion 20/20 in one eye and not less than 20/40 in the other, without glasses." For the re-examination of the men in the different branches of the service at stated times a different standard is required; for "Class A, not less than 20/30 with both eyes open without glasses," and for "Class B, not less than 20/40 with both eyes open without glasses."

The acuteness of vision is tested not only with cards on which are printed letters subtending the standard angle of five minutes, but also with some cards which I prepared for the New Haven road, on which are printed small semaphore arms of such size that the length of the arm at twenty feet subtends a visual angle of five minutes, and the width of the arm an angle of one minute; this corresponds to the apparent size of a standard semaphore arm when seen at a distance of 2600 feet, which would be sufficient for railroad work. It is found, by using these cards, that men can read easily the position of the semaphore arms at 20 feet who have only 20/30 of average normal vision, for the position of the signal at danger (horizontal) or at safety (inclined) can be seen much more easily than the difference between such letters as O, C, D, etc., and a man who has 20/30 or better when tested by the letters can read easily the signals at the required distances. In fixing the above standards of vision the object has been to require for entrance to the service, or for promotion, in those positions where good eyesight is essential, such a standard as will ensure 20/20, or the average vision of normal eyes, and for men in other positions, to require this *in one eye and at least one-half of this in the other.* For the re-examination of men in the service who have become familiar with their duties, and by reason of their experience are more valuable employees, a lower standard has been fixed which was considered safe for a continuation of such work. In connection with the test for vision, I wish to say a word in regard to the necessity for using both the lantern, properly arranged, and the colored worsteds, in making the test for color-sense. We must keep in mind the fact that both in railroad and marine service it is necessary not only to distinguish colors which are spread over a considerable surface, as in a signal flag, but also to read the color of a distant signal lamp which is focused on a very small central portion of the retina, and a number of cases are found where the color of flags or test-worsteds can be seen well enough to pass the tests, but where the central area of the retina is impaired in its color-perception over a space large enough to prevent it from seeing accurately the color of a distant signal lamp. Such a test has been used for many years in Holland, and for more than a year the New Haven road has been using an improved lantern which I designed for them, which has been very satisfactory, and at a later session of this meeting I hope to have the pleasure of showing you the latest form of this lantern.

Dr. Albert E. Bulson, Jr., Fort Wayne—I am very glad to hear Dr. Allport say that he does not approve of trainmen wearing glasses for distant vision; I fully agree with him. About one year ago an old engineer on the western division of the Pennsylvania railroad was operated on by me for double cataract, the result with cataract glasses being practically 20/20 vision in each eye. An application for a position as yard-engineer brought an enquiry from the railroad officials as to the amount of vision, and asking for an opinion as to the propriety of allowing the applicant to wear glasses while on duty. While admitting that the applicant had the required acuity of vision in each eye I did not advocate allowing employees in the train service to wear glasses, as the steaming and frosting of the lenses at certain times would render them useless, so far as obtaining satisfactory vision through them is concerned. This same opinion was advanced in the case of another engineer who had but 20/50 vision in each eye without glasses, and 20/20 vision in each eye with glasses.

As to testing the vision of railroad employees I believe intelligent *railroad officials can, if properly coached,* make as satisfactory examinations of the vision, both for acuity and color-perceptions, for all practical purposes, as nine-tenths of the medical men.

Dr. C. F. Clark, Columbus, Ohio—We have with us a pioneer in this work, Dr. Thomson, of Philadelphia, who over twenty years ago established a method on the Pennsylvania road and issued instruction under which the examiners should work, and I have for sixteen years been working under that system. I do not know that the Doctor now has any reason to criticise that method, and it has been in operation long enough to test it. Dr. Allport has called attention to one point that might perhaps be improved, and that is in always having the first examination made by an oculist. I can not help thinking it is a mistake to allow non-medical men to make the first examination, for if the preliminary examination was made by an oculist he might often detect conditions, which, while not interfering with a man's ability at the time, would indicate that he would not be able to continue in this as his life work, whereas in some other line of work he would be worth twenty or thirty years of good service. The railroad men are better able to determine a man's ability to remain in his position than they are to determine his ability to enter the service.

Dr. William Thomson, Philadelphia—I have been so much pleased with Dr. Allport's paper that I would like to make a motion to extend to him, as we did to Dr. Hansell, the thanks of this Section for such an excellent report. (A vote of thanks was adopted.)

Of course, as some of you know, long before 1880 this was a burning question, and my old colleague, Dr. Jeffries, of Boston, and myself were quite obnoxious to the railroad people of the country, if not to the American Ophthalmological Society, for the manner in which we pressed the question of color-blindness. When the matter was presented to me by the Pennsylvania Company in 1879 to see if I could invent some method of practical examination, I found that we could not employ the medical men then in the service of the railroad. That led to the adoption of the system in use there since 1880.

Dr. Allport has given us an eloquent account of what would take place in the examination of a road where there was a large number of employees never before tested. Three or four per cent. of color-blind and perhaps 25 per cent. of the men showing poor vision would be found. This method of the Pennsylvania Railroad system has been adopted by many roads, which I think control about 150,000 miles. I would simply say in behalf of the method that it was a pioneer move intended to take the place of nothing, and I hope it has been somewhat effective in protecting the public and the employees from the disasters of accidents until the present time, when this agitation that Dr. Allport has taken such a good part in bringing about may offer something better.

I agree with Dr. Allport that the examination should be in the hands of oculists wherever possible. Dr. Williams shows us that his road, using the Pennsylvania Railroad method, has made him the examining oculist, for all doubtful cases are referred to him, but if we can formulate something better Dr. Williams and I will both be glad to call the attention of our railroad officials to these points. Now, while Dr. Allport thinks that no examinations should be made by non-professional persons, we have the distinguished example of Dr. Allport *himself in his excellent system of examinations* of school children where the teachers are trusted to make the original examinations.

Dr. C. H. Williams, Boston—I should like to say that your Section appointed a Committee at the Philadelphia meeting to consider the question of the vision of railroad employees, which practically deals with this same subject. That Committee reported in Denver, a majority and a minority report, and the matter was referred back to the Committee, which was enlarged from three to five members, Dr. Allport being chairman. The Committee decided not to report this year, because the subject is coming up for discussion at the International Congress this summer in Paris and it was thought best to wait until we had a chance to go over the findings of that International Committee before making a final report. It would seem to me best to refer this paper to the existing committee and let them report on it next year

Dr. Lippincott—I accept Dr. Williams' suggestion.

The Chairman—Then the paper will be so referred.

Dr. J. A. Lippincott, Pittsburg—I would move that the paper of Dr. Allport be referred to a committee, appointed by the Chairman, who shall use it as a basis in drawing up some practical resolutions to guide us in this work.

Dr. Allport, closing the discussion—I desire to say that we all surely bow to our friend, Dr. Thomson, in matters pertaining to this subject, as he certainly has accomplished more than any one along the lines referred to in my paper. If I failed to mention Dr. Thomson's name in my article when drawing some of my conclusions from his writings, it was because we are all so familiar with his work, and feel it to be of such a standard character, that it hardly seems necessary to go on quoting him whenever an article is written on this subject. I wish to thank the Doctor for the kind words he has said concerning my paper, and am delighted to learn that it coincides with his views, especially concerning the opinion that the time has arrived when eye and ear examinations should be made by medical men. Dr. Thomson certainly makes an apparently reasonable argument when he refers to the fact that I advocate the examination of school children by teachers, but do not recommend the examination of railroad employees by non-medical men. It certainly seems to be a lack of harmony between two views, but I think a careful analysis will disclose the dissimilarity between the two conditions. School children should be annually examined in enormous numbers. For instance, during the last few weeks in Chicago the five thousand school teachers in the city have examined about two hundred and fifty thousand children. The expense involved in such examinations by medical men would be an insurmountable obstacle to the work being ordered by the various boards of education, besides that, the examination of children by physicians, concerning whose selection parents have nothing to say, would create a storm of opposition from the ranks of the laity, and I am sure we all, as medical men, understand that the selection of certain eye and ear surgeons to examine every child in a city would engender professional strife and jealousy sufficient to stop the whole proceeding. Then the dangers involved between the examination of school children and railway employees are not at all similar. The preservation of life and property is vitally involved in the examination of railroad men, which certainly is not the case in the examination of school children. These and other arguments which might be produced appear to me quite sufficient to demonstrate that, while I believe eye and ear examinations of the character which I recommend can be made with sufficient accuracy by school teachers, where defective children are always advised to consult a medical man, the examination of railway men can only be made with safety by physicians.

Dr. Williams expresses some dissatisfaction that the three roads with which he is connected are not included in my statistics. I beg leave to assure the Doctor that no one regrets this more than I. I desire to say, however, that it is not my fault. Letters of inquiry were sent to these three railroads with question blanks enclosed, and they were earnestly requested to assist me in completing the statistics. They, however, saw fit to ignore my letters, and, of course, I could not compel them to reply. I sincerely hoped that every road in this country would reply to my letters, but many of them have not done so. I think that after the interest that has been expressed in this paper by the Section, I will in the course of the next year endeavor to secure reports from those roads that have not reported, in order to be able to present complete statistics on the subject.

Dr. Williams thought that switchmen, and some other employees directly interested in the moving of trains, should not be required to possess perfect vision on entering the service. I can not agree with the Doctor on this point. I see no reason why railroads should not require perfect eyes and ears from men when they for the first time enter their service. There are plenty of men seeking railroad employment and it is not a difficult matter to secure those in reasonably perfect physical condition. Probably no one enters railroad service without ambition, and without the hope of advancement. The switchman of to-day hopes to be the fireman or the engineer of to-morrow. Why, therefore, is it not an unnecessary injustice to both the railroad and the man himself to voluntarily select a man below a perfect standard? I can see the force of the argument in favor of great leniency toward old employees, but I can not understand Dr. Williams' position. Dr. Williams also says that 20/20 of vision, with both eyes open, should be considered sufficient. This argument is to me even more inexplicable than the other; for however good vision may be in one eye, the other eye may be extremely defective, lost, or even glass for that matter, which should, I think, certainly disqualify a man from assuming the charge of an engine run at the rate of 40 or 50 miles an hour. Concerning the semaphore arm, we must bear in mind that this is not the only signal used on the railroads, even where the semaphore is adopted. There are many railroads in the country where the semaphore signals are not used at all. If we are to make recommendations that are to be adopted by railroad and medical men, we should make them of such a character that will be consistent and usable on the roads. The opinion has been expressed that non-medical men are competent to make these tests. I can not agree with this view. We know that this system has been used on the Pennsylvania road and on other roads, and we also know that excellent work and results have been achieved, and at the time that this work was inaugurated by Dr. Thomson it was a great step in advance of anything that had heretofore been employed; but I think the time has arrived when we are in a position to take a step further and endeavor to bring about the physical examination of railroad men by physicians, and not by members of the laity. If I understand Dr. Thomson correctly, he himself is now in favor of this plan. If any of you have examined large bodies of men for railroad service after they have been examined by non-professional men, I am sure you will agree with me that such examinations are not safe. I remember one railroad engineer who was sent to me for examination who had been examined two or three times by non-medical examiners. He had a vision of 20/200 and had passed several so-called examinations. He told me that he had never in his life seen better than 20/200, and I have no reason to doubt his statement, as I found he was simply myopic. I obtained for him a vision of 20/20 in each eye by suitable glasses. On the same road I found between 3 and 4 per cent. of color-blind men, after they had passed the examination by non-medical men, and you will remember that this is about the percentage that we find among men who have never been examined.

I desire to thank the Section for the cordiality with which they have received my paper.

OPERATIONS FOR SECONDARY CATARACTS.

PETER A. CALLAN, M.D.

NEW YORK CITY.

It is a safe assertion that at least one-third of all cataract extractions require a secondary operation to obtain satisfactory vision. What constitutes satisfactory vision must vary with the different needs of our patients. The uncultured laborer requires less than the educated professional gentleman or business man. The laborer with a vision of 20/70 is able to earn a living and read type as he would naturally choose, while the educated man of affairs would look for at least 20/40. Even with that amount I do not hesitate to do a secondary operation, provided the patient is willing to

---

* Presented to the Section on C [illegible] Fifty-fi Annual Meeting of the Ameri [illegible] A., held Atlantic City, N. J., June 5-8, 1

assume his share of the risk. When the vision is 20/70, or less, I suggest to the patient the advisability of an operation to improve the sight.

We can divide the so-called secondary cataracts into two classes, the simple and the complicated form. The former consists of hyperplasia of the epithelial cells of the anterior capsule with more or less lens matter. The complicated form has, in addition, exudate due to inflammation of iris, ciliary body, or uveal tract as a whole.

The time to operate on a secondary cataract should depend on the condition of the eye. If it has become normal in appearance and does not redden up when it is grasped by the fixation forceps, we are generally safe in our presumption that it is quiescent, and will not unduly react after the operation. Personally, I prefer to delay the secondary operation for a period of months after the extraction, rather than run any unnecessary risk by undue haste. In all surgical procedures there is the ever-present danger of infection, due to surgeon, instruments or field of operation. The danger from sepsis, following an operation, ought to be of extreme rarity if we are clean in our methods of procedure; still, it does occur, with loss of eyes as the net result. It is poor consolation for the patient after the loss of an eye to learn that the surgeon thinks that the infection was introduced at the time of the cataract extraction. If such were the case there is no question but that the secondary operation was done too soon and might have been avoided by waiting. Aside from infection, the great danger is from traumatism exerted on the ciliary processes, and if this can be avoided, we can perform secondary operations without dreading an unfortunate outcome. The attacks of glaucoma and iridocyclitis, which often ensue, are in the main due to faulty methods employed or interfering too soon after the cataract extraction. We can attribute our disasters to operating too soon and exerting too much traction—in the effort to obtain a clear pupil—on the ciliary processes.

The underlying principle which ought to guide us in operating on pupilary membranes is that we should cut and not attempt to tear them. Personally, I now limit myself to two methods in operating on all forms of secondary cataracts.

When the pupilary membrane is thin and veil-like, of uniform color, without whitish bands across its surface, I use Knapp's knife-needle according to his method. Having a dilated pupil, make two incisions in the membrane; the first should be above in the horizontal plane, the second from below upward to the first, thus making a T-shaped opening. The corneal puncture is made about 3 mm. from the limbus, up and out or inward, as is necessary in the right or left eye.

If the membrane should be tough, the knife-needle does not cut, but it is likely to tear, if we exert force, and drag on the ciliary processes. I was unfortunate in using this method and lost an eye from iridocyclitis: I had made a cataract operation on both eyes of a woman of 65 years. The last extraction was about one year before I did the secondary operation. The eye last operated on had a thin web-like membrane in the upper third of the pupil, while the lower two-thirds was crossed by a white band. The upper horizontal cut was readily made, but in attempting to make the vertical incision I met with considerable resistance and must have used too much force, which resulted in the loss of the eye.

I had another case, with a better final outcome—a young man with a soft cataract, where three incisions had absorbed the lens, leaving a thin pupilary membrane, which was diagonally crossed by a narrow band, cord-like in character. In this case I did not succeed in cutting through the band with the knife-needle; I withdrew the needle, enlarged the corneal opening and introduced the forceps-scissors into the anterior chamber and readily cut the resisting band without any difficulty. A mild attack of cyclitis resulted, which kept him in the hospital for over three weeks. Patient was discharged cured.

For the past several years I have used the forceps-scissors of De Wecker, to the exclusion of all other methods in operating on thick or tough pupilary membranes, where the lens has been removed, either by extraction or absorption. I consider De Wecker's model the best. The forceps-scissor blades should be 13 to 14 mm. long from point to heel and not to exceed 2 mm. in width when closed, and the greatest thickness 1.75 mm.

In using the forceps-scissors the corneal opening should be selected so as to give free play to the instrument within the eye. With an occluded pupil make the corneal incision about 2 mm. from the limbus, but with a mobile pupil the corneal opening should be opposite the point of maximum dilatation, otherwise we are very likely to button-hole the iris. The iris falls forward with the escape of the aqueous and comes in contact with the scissor blades. In the case of children it is imperative to work quickly, otherwise the iris sphincter contracts and covers the opening in the membrane, so that it is not possible to insert one of the scissor blades behind the tissue to be cut. I find Agnew's angular keratome, which is 16 mm. long and 4.5 mm. wide, the most satisfactory instrument for making the opening in the cornea and membrane. It is long enough to reach any part of the anterior chamber where we may wish to pierce the obstructing tissues. The modus operandi is as follows: Incise the cornea at any point from 2 to 4 mm. with the keratome; then partially withdraw the instrument, elevate the handle and gently push down the point through the tissue to be cut by the scissors. The opening need not exceed 2 mm. and the keratome should not enter deeply into the vitreous. Having withdrawn the keratome, insert the blades of the forceps-scissors closed; when within the anterior chamber, open scissors and push one blade through the opening in membrane, then cut. If the tissue is tense and on the stretch, one cut is enough, but with a flaccid membrane, two are necessary in order to secure a V-shaped aperture. If we have to deal with a small occluded pupil, simply limiting our incisions to pupilary area will not be sufficient; it then becomes necessary to include the iris sphincter, if not more, in order to secure a satisfactory result. I prefer to cut the iris above, rather than below, for cosmetic effect. In operating on eyes without displaced pupils, due to prolapse or incarceration of iris, it is necessary to make three incisions with the scissors, one on each side to free the iris from the traction to the corneal cicatrix and a vertical cut through membrane and iris. The lateral incisions should be of sufficient length to free the involved part of the iris, and the amount of pupil displacement should guide us as to what length to carry the downward cut.

In nuclear, perinuclear and soft cataracts of the young, where we have made several discissions, the result is not always quite satisfactory, owing to thickened capsule containing more or less unabsorbed lens matter. The further use of a discission needle is not advisable; while it might cause some more absorption, there is still the opaque capsule. I have found the following method most satisfactory: In young children general anesthesia is imperative. With mydriasis of pupil, incise cornea opposite upper border of sphincter, insert the point of keratome about 2 mm. below upper edge of dilated pupil, through capsule and its contents. Withdraw keratome with as little escape of aqueous as is possible. Introduce forceps-scissors through corneal section; insert one blade through and behind the capsular opening; then cut downward to the iris, pushing the upper blade behind it and continue the incision almost to the periphery. In traumatic cataracts of long standing, especially of the young, where most of the lens has disappeared, and in unripe senile cataracts after extraction, leaving considerable lens fibers within the closed capsule, the forceps-scissors, when properly used, give most excellent results. When there is considerable lens matter it is often necessary to freely cut the capsule in various directions in order to remove the mass by syringing. If we are adverse to introducing the nozzle of the syringe into the anterior chamber, by depressing the posterior wall of the corneal wound, with the syringe held at an angle of 30 degrees, we can force a column of water over the opening and accomplish the same result.

It not infrequently happens that after the division of the capsular membrane it is possible to remove it, in part or the whole, from the eye, without exerting any force, and secure a clear, black pupil. This method is not without its drawbacks; we are apt to lose some vitreous, especially if it is fluid. If it is done too soon after the original operation, before the eye has fully recovered, the opening obtained will not be permanent.

In regard to Bowman's method, the use of two needles for tough membranes, while often very satisfactory results are obtained, by this means we never feel sure of the amount of traction exerted on the ciliary processes. The underlying principle of the method is faulty, inasmuch as the opening obtained through the membrane is done by tearing the tissue, and the tougher the obstruction so much greater is the pull at right angles to the movement of the needles.

As far back as the first quarter of the 18th century Cheselden performed iridotomies with a small one-edged knife, which suggested to De Wecker the forceps-scissors; by means of this secondary cataracts can be removed from the pupilary area, by cutting without any traction, with minimum of reaction as a result of the operation.

DISCUSSION.

Dr. Herman Knapp, New York—I am very sorry I did not hear Dr. Callan's paper. Thus, I shall have to begin where my predecessor left off. He believed that a simple extraction was the ideal method, but that there were many objections to it. I say the simple extraction is not only the ideal method, but the best and safest, and this is not a theoretical speculation, but the experience of over fifteen years. I can say that there is no year within that time in which I have done less than 100 extractions. I make an iridectomy only when there is a complication necessitating it.

The method which I have followed and which avoids almost altogether the thickening of the capsule, avoids also iritis, which is often the cause of the thickening. In the ordinary recovery from cataract extraction there should be no inflammation at all, but a smooth healing of a clean aseptic wound. There are, however, not a few cases where the conventional operation itself is productive of the adhesions. You rupture the capsule in a variety of ways and the lens comes out through the section, but when you look attentively at the iris you will discover many fine ruptures in its pupilary edge which are produced by the out-going lens. You do not see them any more when the lens is out and the pupil back in its place. Adhesions develop at these imperceptible fissures which come in contact with the shreds of the lens capsule. This can be avoided by passing the cystotome through the pupil under the iris and after turning it gently rupture the capsule near its periphery, parallel with the corneal section. This is not so difficult as it appears and is easily accomplished after some practice. The incision of the capsule heals by cicatrization and from the scar you see in some months or years a number of wrinkles in the capsule. By the peripheral capsulotomy the iris is kept away from the capsular wound, and the intact part of the capsule does not come into contact with any of those little fissures at the pupilary edge of the iris. Thus, we obtain a free and round pupil. When a capsule is ruptured in the form of a T—and some seem to think it unusually smart to do this; I saw also Graefe do it—this opening will heal with a T-shaped scar, from both sections of which radiating folds will develop that are unpleasant to deal with.

In regard to this peripheral capsulotomy, it is very necessary that the cystotome should be exceedingly fine, delicate, and very sharp, for there must be no tearing whatever of the capsule, nor of the iris, at any time. When we make this operation with a thin cutting point we get just as clean an incision as in the cornea, and when we dilate the pupil afterward we see the scar very distinctly.

It is not only necessary that the incision should be correct, but it is also necessary to consider the amount of resistance with which we have to deal. If the cataract is hyper-mature we are very apt to dislocate the lens. If the lens is hard, it may be turned round in the capsule; and if the cataract is too dense, we are apt to rupture the suspensory ligament of the lens, which leads to escape of vitreous, either during the operation or afterward, commonly the next day, with prolapse of the iris. The latter is likely to occur in all cases in which the suspensory ligament is frail or defective. If we can detect this condition before the operation, for instance in tremulous cataract, we do best to cut out a piece of iris immediately after the corneal section. When prolapse of iris is noticed the next day, even if it be small, it is best, in my opinion, to abscise it immediately, which can be done easily and cleanly, and the result is just as good as that of a combined extraction.

In the secondary cataract operations, we have to deal with capsules that are wrinkled and nothing else, and I think myself to be of the same opinion with all of you in believing that nothing need be done except to split it with a knife-needle, by a T-shaped or crucial incision, as the case may be. Where there is a thickening of the capsule, the best thing to do is to make the incision at the upper part through cornea and capsule, draw a piece of the latter out with a pair of delicate forceps, and cut it off.

There is a kind of secondary cataract, though, where the capsule, through inflammatory products or whatever it be, produces a dense membrane from one side to the other. If the membrane is not too tough it can be dealt with by the double needle introduced through the same opening in the center. Now, the most difficult ones are those capsules that are not only thickened, but degenerated. In those cases I have made several kinds of operations, and the one I have pursued for a length of time is the so-called cystiridectomy. I go in through the cornea, iris and capsule and take out something of this, either by the hook, which is the most convenient instrument, or by forceps. I have of late, as well as formerly, used the De Wecker forceps-scissors and their new modifications by Esberg and Schweigger. I have had some good results from this procedure, but in those cases where there is much cicatricial tissue there is no method that is entirely satisfactory, for the new pupils are apt to cl[illegible] some i[illegible] they will do this three or [illegible] are c[illegible] which I know no remedy.

I ought to say some[illegible] particular glaucoma foll[illegible]s. are much better than t[illegible] speak from a very large experience. I am quite sure my experience with this operation reaches 2000 or more cases, and I can not say that any eye has been lost. In a number of cases increased tension occurs, but it is controlled by eserin or pilocarpin and injection of morphin, and as soon as you use those remedies a great many of the irritative symptoms of the first night when the eyeball is hard, will disappear, but there are a certain number of cases where the glaucoma is not controlled by these measures and has to be treated by iridectomy. A simple paracentesis does not cure all cases of glaucoma after division as Pagenstecher asserts.

Dr. H. V. Wurdeman, Milwaukee—May I ask what is your procedure for endeavoring to make peripheral capsulotomy when you find that the lens turns?

Dr. Knapp—Those cases are rare, but the best thing is to press a little more on the cornea opposite the lower edge of the cataract. The lens then may come out through the pupil as usual, or turn about 180 degrees on its horizontal axis and you may witness a breech delivery that will please you.

SYSTEMATIC CLEANSING OF THE NASAL CAVITIES BEFORE OPERATIONS WHICH INVOLVE OPENING OF EYEBALL.[*]

J. A. LIPPINCOTT, M.D.
PITTSBURG, PA.

Operations which involve penetration of the ocular tissues, such as cataract extraction, discission, the removal of foreign bodies from the interior of the globe, and iridectomy, whether optical, therapeutic or preliminary to the removal of cataract, are sometimes followed by inflammation of different degrees of intensity, with results varying from a simple and possibly harmless synechia to a destructive panophthalmitis. A considerable portion of these unfortunate results may be prevented by a well-executed operation characterized by a sufficiently large incision, gentle manipulation, careful cleansing and accurate approximation of the lips of the wound. But the most perfect operation—from a mechanical point of view—is occasionally the first step in a series of changes which, passing through corneal infection and suppurative inflammation, terminates only with enucleation of the eye.

The measures usually taken to prevent infection have reference to the field of operation and to the preparation of the instruments. In regard to the former, the precautions generally employed, viz., conscientious cleansing of the conjunctival sac, the lid edges and the adjacent parts of the face, together with flushing of the sac with some mild antiseptic, such as a weak solution of the bichlorid or of the cyanid of mercury, are probably as good as could be adopted.

As to instruments, the modes of preparing them perhaps most commonly employed, viz., letting them remain in alcohol for twenty to thirty minutes, or holding them in boiling water for a few seconds, are not theoretically correct, i.e., they will not successfully stand the ordeal of a culture-test. Many such tests made by myself and my assistant, Dr. Joseph L. Duncan, proved that purposely contaminated knives were not sterilized after immersion in alcohol of any strength for twenty-four hours and that boiling for twenty seconds by the watch was also ineffectual. The method which I employ and which, besides being practical, stands rigid bacteriologic tests, is to keep the cutting instruments constantly immersed in a liquid consisting of formalin, 20 per cent., and saturated solution of biborate of soda. Other instruments are boiled for fifteen or twenty minutes in borax solution.

While, however, I am a purist in practice I am not disposed to question the practical efficiency of methods which may be imperfect from a theoretical point of view. You are probably familiar with the opinion of Professor Knapp,[1] expressed some years ago, to the effect that a smooth instrument like a cataract knife, if carefully washed and wiped, might be regarded as surgically clean. Furthermore, I used the alcohol method for many years and I do not believe that any case of infection which occurred in my practice was due to unclean instruments. In point of fact, I am convinced that the principal source of infection in eye operations as now generally performed is to be sought neither in our instruments nor primarily in the conjunctival sac. In a paper read by me before the American Ophthalmological Society, in 1891, occurs the following passage: "I am inclined to believe that in a considerable proportion, if not the majority, of these cases of obscure causation, the *fons et origo mali* is in the nasal chambers, from the intricacies of which, as from an almost inaccessible stronghold, armies of micro-organisms, scenting out with fell sagacity the operative breach in the cornea, crowd through the lachrymal passages into the conjunctival sac. Hence, though much has been and much can be done to minimize suppuration following operations on the eyeball, we can scarcely expect to wholly eliminate it; for although we can sterilize our hands, our instruments, and the parts surrounding the eye, we can never be sure that the conjunctival sac is, or will remain, free from germs unless we seal up the puncta, a procedure likely to be resorted to only in exceptional cases. We may, however—and it would probably be good surgery—carefully examine the nasal cavities in all cases before operating, and, where disease of this region is observed or suspected, apply a more or less prolonged preparatory treatment. Indeed, no harm can, and much good may, result from spraying the nostrils with an antiseptic solution before the operation in every case. In opposition to the view here expressed, it might be urged that nasal catarrh is a very common affection, while corneal suppuration after operation is rare. The explanation may lie in the facts that nasal catarrh usually exhibits no purulent tendency, that if there are pus germs in the nasal cavities, they need not necessarily reach the eye, and that even if they do, the invaders may be routed by those not yet well-understood agencies which fight for the integrity of the tissues."

The impossibility of sterilizing the conjunctival pouch, demonstrated by Gayet[2] thirteen years ago, is easily accounted for by the free communication through the tear-passages with so prolific a breeding-ground as the nasal cavities. Out of 100 gelatin tubes stabbed from the nostrils of adults making no complaint of nasal symptoms, 94 contained micro-organisms, among which were bacilli, staphylococci, streptococci and other forms of micrococci. Such a condition of things was to be expected, from the fact that the nasal spaces are the gateways and in a certain sense the filters through which passes or should pass all the air we breathe.

Although I have been for ten years in the habit of giving attention to the nose in cases that appeared suspicious, I did not until comparatively recently commence the method which I now employ and which is as follows: A few hours before operation, in every case, a spray of potassium permanganate, 1 to 2000, is thoroughly applied to the nostrils. In some cases the spraying is repeated imediately before the operation, and, where there is decided evidence of nasal disease, each of the three or four days succeeding it. The permanganate spray, besides not being specially unpleasant, has potency enough to destroy a large proportion of the organisms with which it comes in contact, and to lull most of the rest into a beneficent inactivity until the corneal wound is closed. This procedure has been carried out in each of my last 152 operations in which the globe was penetrated. Of these, 60 were cataract extractions, 17 were discissions, 21 were operations for the removal of foreign bodies, and 54 were iridectomies for optical purposes, for glaucoma or for chronic iritis, or were preliminary to the extraction of cataract. In these operations there was not only a complete absence of any sign of suppurative inflammation, but there was an unusual degree of freedom from inflammation or irritation of any kind, although a number of the cases were of an unfavorable nature. The wounds healed with less than the usual degree of redness, and convalescence was more speedy than in my previous experience. By way of illustration I shall cite two cases.

---

[*] Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Transactions Am. Ophthal. Soc., iv, 195.

[2] Archives d'Ophthalmologie, vii, 353.

Case 1.—Mrs. W. Y., aged 62, had been operated on by myself for cataract affecting the right eye, in 1896. The operation, which was entirely satisfactory, was followed by corneal suppuration, hypopyon and very violent iritis, which kept her in her room for nearly two months and left her with the iris extensively adherent to a very opaque capsule. It is true that discission subsequently gave her good vision—with $+14=20/30$—but the experience was a long and trying one, both to her and to myself and came nearly ending disastrously. In June, 1899, I operated on the other eye, having sprayed the nose well with the permanganate solution. This time, healing kept on promptly, painlessly and almost without redness, and the patient went home on the eighth day without a synechia or other sequela of iritis. Corrected vision some weeks later was 20/20+.

Case 2.—Mrs. E. L., aged 64, had double-sided cataract, complicated with myopia and extensive choroidal atrophy. The left eye was operated on by me Jan. 21, 1898. Operation was followed by severe iritis. Eventual recovery, and with +2.5 ⊂⊃ +2 cyl. horizontal, vision = 20/70. In May, 1898, preliminary iridectomy was made on R. E. Notwithstanding free use of atropin intense iritis ensued, causing firm adhesion of the lower three-fourths of the pupilary margin. On Nov. 2, 1898, after freely spraying the nostrils with the permanganate solution, the iris was dissected from the lens and the latter removed. Healing process was rapid and smooth, without any iris trouble. The resulting vision was quite poor, only 3/200, but this was explained by the existence of a large area of complete atrophy of the choroid in the neighborhod of the macula.

I have long been of the opinion that the introduction of pathogenic—not necessarily pyogenic—germs is more common after the more important operations on the eye than is perhaps generally supposed, and that to it may be attributed in a large measure the not very infrequent cases in which post-operative inflammation of the iris and other tissues is observed.

As a measure of prophylaxis against such inflammations, as well as against infection of the corneal wound with its dreaded consequences, I think that systematic cleansing of the nasal cavities by means of permanganate of potassium solution or some similar agent will prove a useful addition to our antiseptic precautions.

DISCUSSION.

Dr. G. E De Schweinitz, Philadelphia—Since the first of the year I have followed Dr. Lippincott's method, using a solution of 1 to 5000, and have employed it in perhaps thirty or forty operations. It has been my experience that the spray seemed to reduce the hyperemic condition of the conjunctiva which sometimes follows extractions and various operations. Most of these operations were done in the hospital, where I deal with a poor class of patients. I have seen disagreeable results only once, and they occurred in a man who sneezed thirty times after the first atomization. Sterilization of the nasal cavities is a proper procedure, and as permanganate of potassium is a powerful antiseptic, it would seem suitable for this purpose.

Dr. J. A. White, Richmond, Va.—It has always been my practice when there was any trouble with the nose to cleanse it prior to an eye operation. In the methods of cleaning our instruments we may differ somewhat, the main thing being to have the instruments and the field of operation as sterile as possible. I have followed Dr. Lippincott's method and I use the formalin sterilizer, but in the preparation of my patient for operation I have for many years back, notwithstanding the fact that many observers claim that it is impossible to get the conjunctival sac sterile, tried to get it as sterile as possible. The method I have used for ten years has been so satisfactory that I want to give the results of that experience. It is my habit always in preparing a patient for cataract extraction to sterilize the face and to irrigate the conjunctival sac thoroughly with normal salt or 1 to 10,000 bichlorid solution, and afterward to fill the eye with a preparation that I call sterilized vaselin. This is made by adding 1 gr. of bichlorid and 5 gr. common salt to 6 ounces of vaselin. The salt may be dissolved in a little water and the vaselin is boiled, although it is usually claimed to be sterile, and the solution of salt is then easily incorporated. Then I have a cotton pad dipped in bichlorid placed over the eye and hermetically sealed and the eye is not opened again until the patient is on the table for operation. If left on over night, I usually find on opening it that much of the application has been absorbed. As soon as the operation is concluded I fill the eye again with this same preparation. The amount of irritation is not more than that which commonly follows a drop or two of cocain solution. I have had a long and very successful experience in operating and have never had a case of sepsis of any kind, nor any of the complications I used to meet with prior to the time I adopted this method.

Dr. R. S. Magee, Topeka—I simply want to mention the fact that in troublesome ulcerations of the cornea I find that the cleansing of the lachrymal sac, as well as the eye, gives beneficial results. No doubt you have all found ulcerations that will not heal under the various plans of treatment, and can not be expected to until the nasal sac and passages surrounding are thoroughly cleansed. The solution I use is a saturated boracic acid.

Dr. C. A. Veasey, Philadelphia—I simply desire to add my testimony to the efficacy of the method advocated by Dr. Lippincott and which I have now been using for upward of a year. Before I began to use the intranasal sprays of potassium permanganate, previous to operations involving the opening of the eye-ball, it was my custom to employ some mild antiseptic alkaline spray, preferably Dobell's solution, but since I have adopted the new plan I get better results than I did before.

I have met with the complication referred to by Dr. De Schweinitz, that of sneezing, and it is exceedingly annoying. Occasionally a small amount of the solution penetrates the accessory sinuses of the nose and will trickle into the posterior nares after the patient is laid upon the table, producing the paroxysms of sneezing. Another complication I have met with in a small number of cases has been an intense nausea produced in patients of delicate sensibil[illegible] red [illegible] few weeks ago that it produ[illegible] like odor of a dead [illegible] and wa[illegible] that I use of it. These cases are rare and should not deter us from its employment in most cases.

Some time ago I adopted Gifford's method of wiping that portion of the cornea to be penetrated, just preceding any operation involving the opening of the ball, with a pledget of moist absorbent cotton, and I am quite sure the method often prevents germs from being carried into the eye at the time the instrument enters.

Dr. S. Lewis Ziegler, Philadelphia—As Dr. Lippincott knows, I have been interested in the nasal end of eye surgery for some time, but I have not used the permanganate solution. I have used a solution of silico-fluorid of soda, as recommended by the late Dr. Goodman. In cases where there is real danger of infection from the tear-duct a suture placed in the cornea after the operation and the wound treated as an open one, either with or without ice, with frequent use of an antiseptic wash, has prevented any complications in the way of infection.

Dr. G. A. Aschman, Wheeling—In cases where there is purulent condition of the nasal sac and canal, or ozena, I have found valuable help by closing the lachrymal puncta. At the Detroit meeting I read a paper on the treatment of dacryocystitis and advocated this measure. They are closed by introducing the electric cautery almost up to the end of the canaliculus. I think you will all come across cases of this kind, and I believe that by this method the so-called inoperable cases will be done away with. There are cases that can not be postponed, and I believe this is an efficient way to operate on them.

Dr. Lippincott, closing the discussion—I can add only a word to what I have already said. As to the sneezing, curiously enough I have not seen it, but no doubt the next dozen cases I operate on will all sneeze, as things generally occur that way. My patients have not complained of the spray being especially unpleasant, but I do not allow the spray to get back into the throat, making the patient sit with the head bent forward, and stopping for a moment or two when there is any sign of the fluid getting into the pharynx.

Dr. Aschman's suggestion of closing the punctum is, of course, a very old matter, and was referred to in a part of the quotation I did not read. Most of us do not wish to seal the punctum in ordinary cases, and it is only applicable to the cases he referred to. Where the nasal duct is thoroughly probed and syringed, I have never had any trouble with cataract operations.

A CASE OF COLOBOMA OF EACH LENS WITHOUT COLOBOMA OF THE IRIS OR CHOROID.[*]

JAMES MOORES BALL, M.D.

Professor of Ophthalmology in the St. Louis College of Physicians and Surgeons; Ophthalmologist to St. Joseph's Ophthalmic and Surgical Sanatorium.

ST. LOUIS.

Instances of coloboma of the crystalline lens are so rare—only about seventy having been recorded—and bring up so many interesting questions for discussion, that I feel justified in directing your attention to a case in point.

S. B., male, white, aged 14, was brought to me on Oct. 7, 1899, on account of defective vision. The parents state that he was a delicate child and never was able to see distinctly. Seven years ago glasses were purchased from an optician, and two years since an ophthalmologist prescribed for him.

The boy is an ungainly looking youth; he is 5 feet 7½ inches in height, weighs 100 pounds, wears a 7⅜ hat, and has flat feet and a chicken breast. Four years ago he was operated on for adenoids. With the exception of an attack of scarlet fever he has had no serious sickness. When 3 months old he was salivated. The parents are strong, healthy appearing people. The father acknowledged an attack of gonorrhea before marriage, but denies syphilis. However, a medical friend who knew the father intimately, informs me that he contracted syphilis before marriage. The boy was born eleven months after the marriage of his parents.

The boy is a blond, with blue eyes. To ordinary inspection the eyes appear normal, except for a slight prominence suggestive of myopia. The ocular movements are normal; there is no tremulousness of the irides. The pupils measure 6 mm.

Vision of the R. E.=8/200; of the L. E.=6/200.

The astigmometer of Kagenaar gives the corneal astigmatism as: R. E.=3.00 D. axis 35°; L. E.=2.25 D. axis 135°.

Under atropin the best vision results from these lenses: R. E.=—13.00⊂⊃—5.00 axis 35°=20/50; L. E.=—11.00⊂⊃—2.25 axis 135°=20/40.

After the effect of the mydriatic had passed off, I prescribed these glasses for constant use: R. E.=—12.00⊂⊃—5.00 axis 35°=20/50; L. E.=—10.00⊂⊃—2.25 axis 135°=20/40.

With these lenses he can read, with R. E., Jaeger No. 6 at 10 to 28 cm.; L. E., Jæger No. 2 at 7 to 21 cm.

As remarked by Clark,[1] few cases of coloboma of the lens are recorded in which mention is made of the refraction and accommodation. The reason is that in many of these cases vision is too defective to permit such study.

It will be noticed that in the right eye there is a difference of 2 D. of astigmatism between the findings of the ophthalmometer and the trial case. Retinoscopy shows the amount of astigmatism to be 5 D. I conclude that 2 D. of astigmatism must be lenticular.

Examination of this boy by the ophthalmoscope before using a mydriatic shows coloboma of each lens. The appearance after the use of atropin is shown in the accompanying illustration. No attempt has been made to delineate the retinal vessels. The object of the illustration is to present the defect in the lenses.

There is no coloboma of the iris or choroid. The lens capsule and suspensory ligament are not visible. There is no displacement of either lens. The lenses are transparent up to the lower borders, which appear of a golden-brown color. The fundi are normal.

In looking into literature, I find that most cases of coloboma of the lens show the defect in the lower part. Three exceptional cases are on record: in that of Schiess[2] the lower and outer border was wanting; in that of Lang[3] the defect was directly outward, and in the case of Bronner[4] the coloboma was upward and outward. Doyne[5] has described a case of coloboma of iris and choroid with a projection of the corresponding margin of the lens.

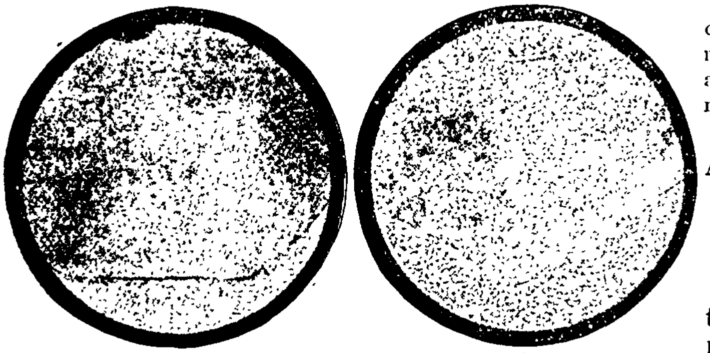
Eyes with coloboma lentis usually present myopic refraction. Bowman[6] and Heyl[7] have recorded cases in which the refraction was hypermetropic. Gruening[8] met with it in an emmetropic eye.

How are we to explain the occurrence of coloboma of the lens? Lang and Treacher Collins[9] say: "The abnormity is caused by some defect in the development of the suspensory ligament. As has been already mentioned, this is developed by adhesions forming between the sides of the lens and the ciliary body at that period of fetal life when they lie in contact. Should some of these adhesions fail to occur, then, as the eyeball enlarged, that portion of the capsule to which no suspensory ligament was attached would not be held taut and made to expand like the remainder; consequently there would be a depression in the lens in that situation. The amount and shape of the deficiency would depend on the extent of the defect in the suspensory ligament. The most likely cause for the absence of adhesions between the ciliary body and the side of the lens, with a consequent defect in the suspensory ligament, would be an absence of the ciliary body; and, as we have already said, a coloboma of the ciliary body is frequently found associated with coloboma of the lens."

---

[*] Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Norris[10] says: "While this feebleness or defect in the zonula is probably the true explanation of some superficial notches, and possibly due to imperfect closure of the fetal slit, the deeper notches in the lens, as has been pointed out by Heyl and Hess, are probably caused by some congenital defect dependent upon an anomalous distribution of the hyaloid artery or of its branches to the posterior lens capsule. The exact nature, however, of such a congenital defect is very differently understood by the two authors just mentioned. Heyl holds that insufficient or arrested development of some of the vessels of the vascular lens-capsule causes an arrest in the development of the lens, while Hess maintains that the defects are due to pressure on the lens by some portion of vascular fetal tissue which has not undergone regressive changes and absorption at the usual time. Bock also believes that the vascular plug of ingrowing mesoderm is a hindrance to development at the points of contact, while Bach thinks that the lens at times becomes too large for the secondary optic vesicle, and that at the point of contact with the ingrowing mesoderm there is sufficient pressure to cause molecular degeneration of the subcapsular fibers, which undergo gradual absorption and leave a notch in their place."



Right. Left.

Which of these explanations is correct I will leave to your judgment. Since only about seventy cases of coloboma lentis are recorded, it must be that the condition is occasionally overlooked, or, if found, remains unreported.

DISCUSSION.

DR. A. B. MCCONACHIE, Baltimore—I have very little to add to the discussion, my personal experience having been limited to a single case, and that not exactly of a character that has been depicted. It was one that, in addition to this defect at the equator, had also a displacement. A boy about 12 years of age came to me two years ago complaining of double vision, which he could avoid by contracting the lids. I could see the dislocated lens upward and outward, and the lower border was slightly excavated. There was also a coloboma of the suspensory ligament, extending completely down to its ciliary attachment. The condition was symmetrical in each eye. Naturally, there was in the lower inner segment a hypermetropic condition and this gave an excellent opportunity by skiascopy to show the myopia above and hypermetropia below.

As to the origin of these faults, I think there is much in the explanation that is hypothetical, and we are not yet able to study them as we ought to. Our study is largely ophthalmoscopical, and our opportunities being limited, we must expect to remain in darkness for some time. In regard to those cases in which the coloboma occurs otherwise than in the region of the ocular fissure there is more difficulty of explanation. I believe Dr. Theobald, of our city, has reported one case in which the cleft appeared in the upper and outer segment. Doubtless those cases are due to faulty development of the suspensory ligament.

DR. GEORGE E. DE SCHWEINITZ, Philadelphia—I would like to put on record a case that came to the Jefferson Hospital Dispensary a few weeks ago, a colored boy with double coloboma of the lens, associated with a coloboma of the iris. The general refraction of the eye in this case was hypermetropic.

DR. R. L. RANDOLPH, Baltimore—I may mention in this connection a case I saw about two months ago of a man with microphthalmus with coloboma of the lower border of the lens, also associated with coloboma of the iris, choroid and optic nerve. It was the first time I had seen the latter condition.

A STUDY OF THE INOCULATION THEORY OF MALARIAL FEVER.*

ALBERT WOLDERT, M.D.
PHILADELPHIA.

At the outset of the discussion regarding the inoculation theory of malarial fever through the agency of the mosquito, it seems best to spend a passing word in giving credit to those who have labored to bring about a revolution of ideas in regard to the etiology of this disease. The man who principally formulated the theory that the mosquito acted as the intermediate host in the life history of the malarial parasite was Patrick Manson, of England. Manson, in a measure, followed the views of Lancisi, of Italy, and of Laveran, of France, in that the malarial parasite through the mosquito first passed into water, and in that way was ingested by man. But Manson did not prove this theory. Ronald Ross, of England, caught the inspiration from Manson, and in India, after months of toil, proved by observation and confirmed by experiments on birds that the mosquito really and in truth did act as the host of this parasite. Thus began the movement toward the proper knowledge of the life history of the malarial parasite. Amico Bignami, under the direction of Battista Grassi, of Italy, was first to prove the inoculation theory in the case of man, on the person of Abele Sola, an inmate of San Spirito Hospital, who voluntarily submitted himself to such an experiment. The work of Marchiafava and Bignami in Italy, of Koch in Germany, and of Thayer in this country, can not be mentioned without praise.

The full development of the theory, and confirmed by proof, that the mosquito acted as the intermediate host in the life cycle of the sporozoa of malarial fever has a far-reaching importance and carries one into new fields of thought regarding the various other unknown hosts which may perhaps act similarly for many of the other infectious diseases.

The keynote of this subject was struck by Theobald Smith, who in a recent lecture delivered before the Philadelphia Pathological Society,[1] stated that in making studies in biology one should record carefully all his experiments made on the lower forms of life, whether they at the time seemed of interest or not to the individual investigator.

Starting on the road in pursuit of the facts in regard to the inoculation theory of malarial fever one encounters at the very threshold the sciences of biology, zoölogy and entomology. History states that the term "mosquito originated on this side of the Atlantic Ocean, such being first used in the West Indies, where, it is learned, the word 'mosquito' meant 'a kind of gnat streaked with silvery white, the female members of which have a piercing and sucking apparatus, and annoy man.' " This term is well founded and is a better one than the word "gnat," which has recently come into vogue by certain writers of the old world. The former term distinguishes the mosquito from gnats in general, from the chironomus, and from various other insects analogous to the mosquito.

For the most part, this article deals with two genera of mosquitoes, namely: genus Culex and genus Anopheles, both of which belong to the natural order Diptera.

The Culex pungens deposits its eggs in pails and drains, or vessels of any kind, around the house, while the Anopheles seeks natural ponds or puddles left after heavy rains, and usually in those places which do not contain fish. The number of eggs deposited by the female Culex pungens is about 200, and at the end of three weeks the full-grown mosquito develops. Several broods are hatched each season. The larvæ of the Culex float with head downward in the earliest stages, and breathe through a pneumatic tube at the end of the tail, but later the mature larvæ—or pupæ—reverse their position and then float with head upward, doubtless breathing through two prolongations or spiracles projecting from the head. When disturbed they wriggle rapidly to the bottom of the vessel in which they are contained. The larvæ of the Anopheles, according to Ronald Ross, lie flat upon the surface of the water, like sticks, and when disturbed they move off with a backward skating motion. Marchiafava and Bignami[2] describe the larvæ of Anopheles as "being brown in color, and always move in a horizontal direction, never in a vertical or oblique one," as do those of Culex. The larvæ of Anopheles live in fresh water, such as streams or artificial lakes which contain green moss or algæ. I have been able to confirm these observations of Ross and of Marchiafava and Bignami.

The Culex pungens may be found in the heart of cities, the Anopheles in rural districts, and frequently in the rooms of patients suffering with malarial fever. The Anopheles is frequently found in barns and near horses or cattle, and may be transported through hay to cities and thus lead to local outbreaks of malarial fever, as pointed out by Marchiafava and Bignami.[2]

One may devise either of two methods in studying the relation of mosquitoes to malarial fever; first, to search for the Anopheles in its native haunts and then for the case of malarial fever; or secondly to find the case of malarial fever and afterward look for the Anopheles.

The mosquito is ubiquitous over the face of the earth. It may be found in the tropics, and in regions of perpetual snow. While on a recent investigating journey to Washington, Rear-Admiral George Wallace Melville, who was on the steamer *Jeannette,* which a few years ago made a trip to the Arctic region, informed me that when in Siberia, between the Lena delta and Yakutsk, about 1200 miles from the north pole, mosquitoes prevailed from June to September, and bit severely during those months. In 1877 and 1883 he visited the west coast of Greenland, 500 miles from the pole, or in latitude 65 to 78.30 north; mosquitoes bit fearfully during July and August, but worse in the former month. In August and September, 1878, he visited Norton Sound, and when at St. Michael's, in the Behring Sea, south of Cape Prince of Wales, and east of Cape Prince of Wales Island, mosquitoes were abundant. He also visited the region of St. Lawrence Bay, westward of Cape Prince of Wales. Here mosquitoes were also found. On each of these expeditions members of the crew were severely bitten, but not one had fever of any kind. I was told that so bad are the mosquitoes in these regions that animals coming down in the warmer months are driven back north again by the swarms of mosquitoes which infest that region.

The mosquitoes obtained in the arctic region and in the collection in the National Museum at Washington and shown me by Mr. D. W. Coquillett, were specimens of the Culex consobrinus, and Culex impiger. Both of these species came from Alaska. The impiger was taken at Sitka, June 16, Yakutat, June 21, Virgins Bay, June 26, and Popoff Islands, June 8 and 16, in the year 1899. It might be interesting to note that one of these specimens was accidentally found in an old box of paper and doubtless would have been thrown out if its presence had been known. The Culex consobrinus may also be found as far south as New Mexico, while the impiger has been found on the Island of Jamaica, by C. W. Johnson. Specimens of mosquitoes caught near the City of Mexico on Aug. 4, 1900, and sent to me by Dr. Manuel Urbino, of the National Museum of Mexico, proved to be Culex tarsalis and Culex impiger (?). Mr. C. W. Johnson has recently shown me a specimen of Anopheles —resembling a crucians—which was captured in Venezuela.

Whether the Anopheles lives in the arctic regions is not known, but should they do so they are doubtless harmless.

An interesting question to be decided is, where do the mosquitoes in our latitude go during the winter months? My observations can only be recorded for the latitude of Philadelphia. In this city, the Culex pungens were abundant during September and the first two weeks of October of 1899. Toward the latter part of October the females apeared to be more scarce, while the males were abundant, and I could not find the former in the cellar or outhouses as formerly. On December 17, a full-grown female Culex pungens was found in the sitting-room of a residence in the center of the city. It was kept alive for nearly one month. On February 4, another full-grown female pungens was caught in the kitchen of the same residence. The weather for a week previous had been intensely cold, and for a few days the thermometer had dropped to 7 degrees above zero. It had evidently come out to get water, for when caught it was adjacent to a hydrant. In captivity it only survived one week. About April 1, 1900, a few moths, gnats and spiders, with very long brown legs, began to appear, but no mosquitoes. I could not find any in the dark corners nor walls of the cellar, nor on the wooden structures of the house, nor anywhere around the furnaces on April 1. Not feeling satisfied, the greenhouses of the Biological Department of the University of Pennsylvania were visited. A brief description of these houses would be: 1, a vivarium containing tropical plants and standing water throughout the year, and kept at a temperature of 60 F.; 2, an orchid room kept at 60 F.; 3, an animal-house kept at 60 F.; 4, a cypripedium room at 65 F.; 5, a palm-room at 69 F.; and 6, a stove-room at 89 F. In all these rooms standing water may be found during the winter. A search of two hours in all of these rooms failed to reveal a single mosquito until I had gone into the animal-house, where a full-grown female pungens was found lying flat on the wall and about three feet above some rabbits, and the same distance from a hydrant. It was devoid of blood.

On May 15, 1900, a search of two hours through Horticultural Hall, in Fairmount Park, from the dark basement below to the roof above, failed to reveal a mosquito of any kind. From October to May the temperature in this building ranges from 65 to 70 F. On going into an outhouse immediately adjacent, a young female pungens was found. On May 19, I had no trouble in finding several specimens of full-grown female pungens in a barn in the lower edge of the city and about two miles north of League Island Navy-Yard, a district in which I had treated a case of estivo-autumnal fever the previous fall.

That mosquitoes survive the winter in the climate of Philadelphia, and that they do not necessarily have to migrate to this region, I offer the following data: Full-grown mosquitoes were caught in this latitude during September, October and November, on December 17, February 4, April 24, and a young specimen on May 15. To complete this series the following may be recorded as told me by others: Mr. Coquillett informed me that a specimen of Anopheles punctipennis was found on the snow in Castleton, Vt., on February 1, when the temperature was 6 degrees above zero. Mosquitoes have been found in Washington on December 23 and January 30. Professor Theobald Smith caught a mosquito in Boston during the last week of March. The series is thus complete, and mosquitoes have been found in this latitude during September, October, November, December, January, February, March, April and May. Whether these insects migrate at all I am unprepared to say.

It is said that they do not fly far from their breeding-grounds.

It seems interesting to know that not one male mosquito was found during the entire winter. Marchiafava and Bignami note a similar experience in Italy.

The males were more numerous than the females up to the latter part of October, then disappeared. Of the first brood captured the following May, probably half were males.

All of my mosquitoes were full grown except the specimen obtained May 15; all were Culex pungens; all but one collection were found on plastered brick surfaces; all were adjacent to some kind of animal, and all were in localities convenient to standing water.

According to observations made by different scientists in various parts of the world, it has been demonstrated that not all genera of mosquitoes are capable of inoculating man or birds with malarial fever. This power so to do appears to rest solely with the different species of the genus Anopheles. However, this much has been proved, that birds suffering with malarial fever, Proteosoma Grassii, have been bitten by the Anopheles, and the disease thus conveyed to uninfected birds through the bite of this insect. Further, Grassi and Bignami have raised the Anopheles from larvæ obtained in districts far removed from malarious localities, which mosquitoes have been transported to other places and there have bitten patients suffering with malarial fever and after a certain number of days these same mosquitoes have bitten uninfected men with the result that malarial fever has been produced.

Ross found that within from two to three days after the Anopheles maculipennis—claviger, or quadrimaculata—had bitten birds suffering from avian malarial fever, there developed in the outer muscular coat of the middle intestine certain bodies which had not been found in the middle intestines of other species of mosquitoes, nor in uninfected specimens of the same genus; and within seven to ten days these spores or sporozooids of malarial fever became stored up in the veneno-salivary gland of the insect and in that state were capable of infecting man.

The malarial parasites in the body of man do not take a similar course. Studies of the human blood reveal the presence of certain small, round, actively motile intracorpuscular organisms. These grow to full development at the expense of the red blood-disc, and subsequently rupture, setting free a number of hyaline bodies that at once re-enter other erythrocytes. These results therefore go to show that the sporozoa or plasmodia of Laveran require for their complete existence two biological cycles, one being completed in the body of man, the other being completed in the tissues of the mosquito.

Previous to this time the species of Anopheles used in the experiments on birds and man have been the Anopheles claviger, or more accurately, Anopheles maculipennis. (Lately identified as our Anopheles quadrimaculata.—Howard.) The Anopheles quadrimaculata, or maculipennis—claviger—acording to L. O. Howard, has been found in eight different localities of the United States, as follows: Texas, Florida, Maryland, District of Columbia, Illinois, Minnesota, New Hampshire and New York. The Anopheles punctipennis has been found in nine different localities, namely: Texas, District of Columbia, Maryland, Vermont, Massachusetts, Pennsylvania, New York, New Mexico and Illinois. I have found the Anopheles claviger—quadrimaculata—in at least two localities near Philadelphia and in the Pocono Mountains of Pennsylvania at an altitude of nearly 3000 feet above the sea level. The Anopheles crucians has also been found in this country. Grassi states that he was first to claim that all species of Anopheles were capable of transmitting malarial fever to man.

The genus Anopheles may be distinguished from the genus Culex by the fact that the Anopheles has spotted wings, the palpi are as long as the proboscis, and when the insect rests against the wall the body points outward, forming an angle with the surface on which it rests. The two posterior legs of Anopheles hang downward, and not thrown up over the back as in Culex. The word "spots" as applied to the minute dots or markings on the wings of the Anopheles, signifies very minute round, oval or irregular dark areas on the upper surface of the wings and may be readily discerned by the naked eye, but better with a small hand lens.. The dots are due to a thicker growth of hair in these regions.

My studies to determine the anatomy of the mosquito consist of making paraffin sections of the entire insect in serial form, thus cutting the insect into about 600 pieces, and staining with Delafield's hematoxylin solution and eosin; further by dissecting the fresh specimen by means of needles under a dissecting microscope.

In a former [illegible] printed in The Journal, Feb. 3 [illegible] that regarding [illegible] previous to [illegible]

I take this opportunity to say that since examining the literature further I find that Mr. Leon Dufour,[3] in the "Récherches Anatomiques et Physiologiques sur Les Hemepterics," Paris, 1833, has shown a chart of the dissected mosquito, as has Mr. Felix Arribalzagas in "Dipterologia"[4] (Argentina), 1891.

Marchiafava and Bignami have had Anopheles to bite patients suffering with malarial fever, and, killing the insects from day to day, have studied the whole life history of the parasite outside the human body. For the development of the sporozooids of the different forms of malarial parasites they found that it was best to keep the insects at a constant temperature ranging from 68 to 86 F. After the seventh day they found the spores accumulating within the salivary glands of the mosquito and were then in a fit condition to inoculate man.

Since the conditions seem to require that the temperature be a somewhat high one, this fact might in a measure prevent the development of the malarial parasites within the tissues of the mosquito in arctic regions. (The isothermal line near the arctic circle for the most part remains at 10° F.). It might explain the absence of malarial fever in regions near the north pole. On the other hand, all the necessary conditions are fulfilled in tropical climates, and here also may be found all varieties of malarial fever throughout the entire year.

As has been previously stated, it has been proved that all kinds of mosquitoes are not capable of inoculating man with malarial fever. This power has so far been proved to rest alone with the Anopheles, the exact reason for which must be solved by future workers. Its solution will doubtless be explained by finding certain differences in the anatomy, the function, or the habit of these insects. Whether there is a difference in the structure of the mouth parts, stomach, middle intestine, circulatory system, salivary glands or its secretions, are questions still *sub judice*. In answer to this question, Grassi has stated that it might be due to the rapidity with which the blood may be digested by the Anopheles, that is, twenty hours sooner than in Culex.

In many regions of this country proof that malarial fever may be inoculated has been a revelation to the physicians of those districts. It also furnishes proof positive of the value of experimental knowledge combined with clinical experience. Clinical experience, be it remembered, is only a form of observation, and will never furnish more than half proof. Proof consists in *observation confirmed by experiment.*

Speaking as one who formerly lived in a malarial district of the South, I shall make the statement that owing to the manifold causes and intermixture of effects which surround this question, it is absolutely impossible for clinical experience to unravel the thread which entangles the question of the etiology of malarial fever. This does not apply alone to malarial fever. Is it not so in all the other infectious diseases? The physician, according to my experience, questioning the patient suffering with malarial fever can not elicit the absolute evidence for which he searches. In over 75 per cent. of the cases the patient will state that he has slept in a region adjacent to water, in a low, damp place, or in an open house, and that he has been drinking water from shallow wells, or, worse still, creek water. Farther than this the mind of the patient will not go. His knowledge only extends to the time when the bilious spell came on, or perhaps the initial shiver.

Several years ago, before the full development of the inoculation theory, I undertook by close questioning to learn, if possible, how patients contracted their chills. The whole evidence led to a labyrinthine skein from which it was impossible to unravel any safe conclusion. Some patients told me positively that they did not drink creek water, but only water from wells or springs, and that they at night slept in open houses. The majority perhaps told me that they had both slept in open houses and drank creek water, or water from shallow wells. Instances have been cited in which expeditions have gone into malarial districts without drinking creek or well water and that they had no chills. And from this the conclusion is reached that infection forsooth must take place through the gastrointestinal tract. One may well ask, what about infection through the inspiratory tract, and also about the question of immunity at that definite time? By whichever road one may travel at least one of them leads up to that monument of proof furnished by Ronald Ross, Marchiafava, Bignami, and Koch, that the spores of the malarial fever may be inoculated into the blood of man through the bite of the mosquito.

As to the stamping out of malarial fever various methods have been advised. If the mosquito is to be exterminated in temperate climates, which at the present time seems an impossible task, there may be two periods in which it may be assailed. One would be to kill off the adult and fertilized females during the periods of hibernation, a period in which there are least of them, and secondly to get rid of the larvæ especially during a few brief weeks of early spring. The most direct way of eradicating malarial fever is to isolate all the cases by means of mosquito netting and the judicious administration of quinin.

So far as the Culex pungens is concerned, a very great deal might be done toward limiting its multiplication by giving strict injunctions to the housemaid not to permit stagnant water to remain in pails or buckets about the premises. Another plan would be to point out to boards of health the danger lurking in stagnant water wherever found. The larvæ of Anopheles have been found by Marchiafava and Bignami[2] in stagnant water, and in winter they have found the fertilized females hibernating in caves.

Different drugs and chemicals have been recommended for the destruction of the larvæ of mosquitoes. A culicicide to be of any service must undoubtedly possess many qualities: 1, it must be easily obtained everywhere; 2, it must be inexpensive; 3, when used it must lie on the surface of the water for long periods of time in order to prevent the deposition of eggs by the female; 4, it should be non-poisonous; and 5, it must kill the larvæ or pupæ of the mosquito.

On the morning of May 22, 1900, I found about 100 larvæ of the Culex pungens in an old paint-bucket in the yard of a residence in Philadelphia. These were nearly all in the same stage of development. After their development into pupæ, I decided to make the following experiments with chemicals calculated to destroy them. The experiments thus made consisted of: 1, a strong solution, 120 grains of tobacco to the ounce of kerosene oil (the tobacco to macerate in the oil for 24 hours); 2, a saturated solution (240 grains to the ounce) of camphor in kerosene oil; 3, a saturated solution (80 grains to the ounce) of naphthalin in kerosene oil, and 4, kerosene oil. Two round glass jars were selected, having a diameter of 7 inches (18 centimeters), a circumference of 21½ inches (52 centimeters), and holding a half gallon (2 liters) of hydrant water. Into each glass jar four of the above-described pupæ were placed, one series to be used for the experiment, the other containing the control pupæ.

(The mosquito seems easiest destroyed in the pupa stage since the larvæ may frequently be seen to prevent closure of the breathing tube by biting off the occluding substance.)

Experiment No. 1. Tobacco and kerosene oil experiment: The pupæ on which the experiment was begun were disturbed so as to cause them to fall to the bottom of the jar and on the surface of the water was floated one drop of the tobacco-oil solution. At the end of eight minutes no effect whatever was produced. Now adding three more drops of the solution, all pupæ were practically dead at the end of one hour. The control pupæ remained active.

Experiment No. 2. Camphor-oil series: The jar was now rinsed out carefully until no odor of oil could be detected and four fresh pupæ were placed in the vessel containing a half gallon of hydrant water. The jar was shaken to cause them to sink to the bottom and two drops of camphor-oil solution added. Twenty minutes later no effect was observed. At this time two more drops were added and eight minutes later all the pupæ were sick and were all practically dead at the end of thirty-five minutes. The control pupæ were active.

Experiment No. 3. Naphthalin and kerosene oil series: Four fresh pupæ were placed in the cleansed glass jar containing a half gallon (2 liters) of water and the vessel agitated to cause them to sink, and two drops of naphthalin solution added. Five minutes later one pupa was dead while the other three were active. Eleven minutes later two more drops of naphthalin solution were added and at the end of thirty-seven minutes all the pupæ were practically dead. The controls were in good condition.

Experiment No. 4. Kerosene oil series: Into the cleansed jar containing half a gallon of water were placed four fresh pupæ. After causing them to sink, four drops of kerosene oil were added, with the result that all four pupæ were practically dead at the end of twenty-seven minutes. The control pupæ remained in good condition.

It was evident that four drops of kerosene oil without any other ingredient whatever, acting for a period of from 1 to 37 minutes on four mosquito pupæ contained in a glass vessel 21½ inches in circumference and containing half a gallon of water, was as destructive as kerosene oil containing tobacco, camphor, or naphthalin dissolved in the above-named proportions.

Not feeling satisfied with these experiments and thinking that a smaller amount of one of the combinations might be of greater potency, acting through a longer period of time, I followed the same line of experiments, only this time adding 1 drop of each solution and allowing it to stand from six hours to a longer period. The result proved that the addition of 1 drop of the camphor-oil, or 1 drop of the naphthalin and kerosene oil, or 1 drop of plain kerosene oil produced no effect at all, while the tobacco-oil killed all four pupæ within a period of two hours. The control pupæ which had been used throughout all these experiments remained in the best of condition. To these were added 1 drop of tobacco-oil solution, which produced death in all of them within a period of five hours.

Carrying my experiments still further, I placed four control pupæ in a tub 2 feet (61 centimeters) in diameter and 70 inches (177 centimeters) in circumference, and about 4 inches in depth, and also four pupæ in a similar tub, each of which contained four gallons (8 liters) of hydrant water; to the latter series 6 drops of tobacco-oil solution were added, which caused death to all of them within 4½ hours. The control pupæ remained in good condition during the experiment, and three of them were later killed by the same solution. The fourth one positively refused to die, and after development was given its liberty. Making a rough calculation, the amount of this tobacco-oil solution to be applied to an acre of water for the destruction of the mature mosquito pupæ contained, should be said to be from 44 to 60 ounces. It would be best to renew this fluid every three or four weeks. Frequent agitation aids the fluid in spreading on the surface of the water.

Should the mosquito be the only agent in disseminating malarial fever, the destruction of the larvæ or pupæ of that insect would be only one way of getting rid of the disease. When one realizes that according to Manson 5,000,000 British subjects die each year of malarial fever or its complications, the question assumes mighty proportions. How many die of this disease in the United States I am not prepared to say. They at least run up into the thousands. Regarding the stamping out of the disease in any country Manson suggests the following methods: "1, to begin by administering quinin for long intervals to all cases of malarial fever, since a single man is a source of infection to a whole locality; 2, to cause all persons suffering with malarial fever to sleep under mosquito netting; 3, to compel all the uninfected to sleep in mosquito-proof houses or beds; 4, to kill by different culicicides all mosquitoes entering houses; 5, to destroy all the mosquito larvæ before they reach maturity or the biting stage—to which might be added the destruction of the adult mosquitoes in their places of hibernation—and 6, a combination of all these methods."

[Microscopes for demonstration of sections of mosquitoes at the Atlantic City meeting were loaned through the kindness of Messrs. Queen & Company, Philadelphia.]

THE ATROPHIC PHARYNX.

RALPH W. SEISS, M.D.
Professor of Otology in the Philadelphia Polyclinic; Consulting Laryngologist to the Pennsylvania Institution for the Deaf and Dumb.
PHILADELPHIA.

The literature of the atrophic stage of chronic pharyngitis may be generally classed under the term vague. Writers appear to know or care nothing about the pathologic anatomy of the condition and its relationship to other forms of pharyngeal inflammation seems to be generally ignored. The old term "pharyngitis sicca" is a clinical one, used at random for any form of dryness of the pharyngeal mucous membrane, and bears no relation to any definite form of disease.

All types of simple chronic inflammation of the pharynx tend to progress into the atrophic form. What might be called the average type of chronic pharyngitis is characterized by the enlargement of the lymph-glands, giving the so-called follicles, by dilatation of the superficial blood-vessels, and especially by the formation of small masses of granulation tissue, which are usually situated immediately behind the posterior half arches of the palate. Atrophic areas, showing as sunken, glistening, light-colored spots, occur in the [illegible] portions of the pharyngeal wall. Su[illegible] re-

---

*Presented to the Section on La[illegible] Fifty-first Annual Meeting of the A[illegible] held at Atlantic City, N. J., June 5-8.

main *in statu quo* for half a life-time, seeming hardly to progress, yet never growing better, and giving but a minimum of discomfort. But in a certain number of cases, sometimes dependent on causes known and measureable, but more often for reasons unknown, the chronic interstitial inflammation steadily extends, the areas of granulation tissue become more extensive, and the greater portion of the pharyngeal surface is infiltrated.

The pathologic process is identical with fibrosis elsewhere, the persistent migration and aggregation of leucocytes, their fibrillization and slow conversion into new connective tissue, and the contraction and extension of this formation, with resultant pressure atrophy. In advanced cases the process extends until most of the important structures of the pharynx have been replaced by the fibrous tissue, and the anatomical relations and functions of the organ have been more or less materially changed.

The etiology of this disease, like that of fibrosis elsewhere in the body, is almost unknown. Gouty subjects are certainly more prone than others, and extensive atrophic changes are always present in advanced cases of chronic lithemic sore throat. But it occurs apparently at random among patients of all types, and one might almost say of all ages, and sometimes fails to be present where most positively expected. It follows sclerotic rhinitis, but may exist where the nasal lesions are but slight. Not rarely I have seen it swiftly follow extensive and repeated destructive intranasal operations, but these cases are fortunately now much more rare than they were a few years ago, when the galvanocautery was more popular than at present. In a certain number of cases it is rapidly lighted up by an attack of diphtheria, typhoid fever, or measles, and in many subjects it appears to be distinctly inherited. The clinical history of the atrophic pharynx is that of years of throat fretting, latterly growing decidedly worse. Dry throat, itching, tickling and resultant cough, choking while eating, dull pain which may radiate into the larynx or up toward the Eustachian tubes, and interference with voice, are the commonest symptoms. From the extension of the disease in the larynx, dysphonia is always a prominent complaint in advanced cases. The voice is weak and without staying powers, requiring great nervous and muscular effort to talk or sing for any length of time. Vocal resonance is lacking, and the voice may be called thin, while a constant sense of irritation is produced by its continuous use. The appearance of the atrophic pharynx on inspection is characteristic and unmistakable. Normally, the posterior pharyngeal wall, as viewed from the front with the tongue properly depressed and the part illuminated, is somewhat concave, the surface is slightly rugose, and the color resembles that of the general buccal lining. The atrophic throat, on the other hand, shows a somewhat convex posterior wall, the glandular and muscular elements having disappeared and the centra of the cervical vertebræ pushing the mucous membrane forward in the median line. The surface is absolutely smooth, glistening, and tightly adherent to the tissues beneath. There is generally a line of nearly white or yellow tissue immediately behind the posterior half arch, and the distance between the border of the pendant soft palate and the posterior pharyngeal wall is abnormally great. Engorged and varicose veins may traverse the pharyngeal membrane in any direction, but are especially prominent close to the tonsil and posterior half arches; they are due to cicatricial tissue pressing on the veins and preventing proper return of blood from the part.

The postnasal and laryngeal regions always participate in the general destructive process. Rhinoscopy is easy, and shows the pharyngeal vault to be abnormally large, light colored, and smooth in outline. The Eustachian prominences are pale and contracted, and tubal changes with a greater or less degree of middle-ear sclerosis are almost constantly present. The larynx is noticeably light colored, and the aryepiglottic folds are more or less thinned. Chronic tracheobronchitis is a common concomitant or result in middle or advanced life.

In the nature of things treatment of atrophic organs must always be unsatisfactory so far as restoring their function is concerned. The calm assurance with which practitioners proceed to "cure" diseases due to hopeless alteration of organs is one of the dreary spectacles in medicine. No fibrosed tissue ever returns to a normal condition, no organ so affected can carry out its functions with normality.

The possibilities of treatment in the present state of our knowledge in atrophic pharyngitis are limited to palliation and perhaps arrest of progress. The essentials are to control the migrations of leucocytes and to obtain hyperactivity of the remaining normal tissue element. To bring about this result, stimulant and alterative sprays, such as oil solutions of gaultheria, cinnamon, cubebs, thymol and the like, are certainly of benefit. They should be applied generally by the physician himself, and only to a membrane which has been carefully cleansed by an alkaline spray. Cases of atrophic pharyngitis are generally either markedly irritable or unusually tolerant under treatment; the former class are naturally much the more favorable, and much more satisfactory therapeutic measures can be carried out. The massage effect of properly chosen atomized fluids when driven with a pressure of from 15 to 18 pounds is very decided and most beneficial. The tip of the atomizer should be held about one inch away from the mucous membrane, and the jet steadily and rapidly carried over the entire surface.

In the irritable cases much less can be done, and spraying may have to be limited to inhalations with the tip of the instrument outside the mouth. Pigments applied with the applicator and tightly rolled cotton mop often seem to give more definite results than nebulæ. Thymol solution in alcohol and glycerin, tincture of sanguinaria and glycerin, and copper sulphate, are favorites with me; iodin is sometimes useful. In tolerant subjects much valuable massage can be given by rhythmic and gentle patting of the whole membrane with the medicated mop; if retching, cough, and discomfort result, the method is likely to do more harm than good. Best of all methods of massage and stimulation is the faradic current, the positive pole being applied to the pharynx while the negative is held in the hand of the patient. Many cases will tolerate a séance of two or three minutes with undoubted good result; irritable subjects are best treated by applying the rheophore to the palate and roof of the mouth only. Powders, caustics, strong astringents, and especially silver nitrates, I regard as only injurious in this disease, their use almost always hastening the fibroid process. Operative measures have not been advised by even the most radical of special surgeons; we need to replace tissue, not remove it, and if surgical procedures are necessary for any incidental nose or throat conditions, they should be undertaken with the greatest caution, as every cicatrical area undoubtedly acts as a fresh center in the fibrosis. Palliatives intrusted to the patient may consist of eucalyptus and menthol oil-sprays, lozenges of elm and lettuce, and possibly a sedative gargle. The good effect of the latter is probably entirely due to the necessary muscular action in gargling and not to the medicinal agents employed. Medicated steam inhalations from a really efficient steam atomizer give great comfort, and have some permanent limiting effect on the disease; their use can be continued for months. Internal medication is but a weariness to the patient, so far as altering the diseased throat is concerned; but good hygiene is, of course, necessary, and the correcting of pernicious habits, especially among them the inhaling of smoke, is often absolutely necessary to secure any symptomatic improvement.

Very great comfort extending over long periods and indefinitely prolonged by occasional treatment may certainly be secured by the therapeutic measures outlined in atrophic pharyngitis. The voice will increase in power, the disagreeable sensations lessen or disappear, and the most dreaded sequelæ, sclerotic otitis and chronic bronchitis, may be prevented. But too much must not be hoped for, for patients must be frankly told that their condition is not definitely curable, and accuracy in diagnosis of the actual pathologic factors at work is essential.

DISCUSSION.

Dr. W. Freudenthal, New York City—I am very much interested in Dr. Seiss' paper and would like to make a few remarks on atrophic pharyngitis and rhinitis. You can not separate the pharynx from the nose, especially in these cases. *The principal symptom in atrophic pharyngitis and atrophic* rhinitis is a dryness of the throat, and this is a most important factor. I wrote a few years ago on this topic, and my theories are now acknowledged abroad by a number of men, although I have not heard anything about it in this country. The dryness arises largely from the atmosphere we inhale. The atmosphere of New York, for instance, in winter is entirely too dry, and when it sinks below 40 degrees it is injurious. I have measured for years the dryness of the atmosphere in New York in the houses and schools, and I have often found a relative humidity of 20 per cent., while the highest was only 25 or 30 per cent. The colder the outer air is the more we heat our furnaces and the more hot dry air is driven into the rooms. The air in the furnace is heated and thoroughly dried and the more that is driven into the rooms the more we inhale of it. For a while the nose and pharynx can stand it, but when the rest of the body can not supply the pharynx and nose with sufficient moisture, there sets in at last what is called a dry atrophic pharyngitis and rhinitis. This condition affects mostly the nose, but in the cases where the nose is stopped up the patient will inhale much more with the pharynx, and the dryness *will affect the pharynx chiefly. We should* expect this to occur especially in children with adenoids, but since the process requires years and years to develop we find atrophic pharyngitis most frequently in older people.

The Doctor spoke of the effect of the spray. That is very good and very true. But why not apply massage directly? I devised a few years ago a vibrator and it works very well.

Dr. J. Holinger, Chicago—There is a diversity of opinions as to dry pharyngitis. The fact is that so far we have no intelligible explanation for the pathology of the whole picture. The dryness and moisture of the air, the bacteria and all the other factors are present in people who never had and never will have an atrophic rhinitis or an atrophic pharyngitis. These two diseases, together most probably with a third one, that is, with pachyderma of the larynx, form one group of diseases. One or another of the combination may be lacking; most often it is the pachyderma, but it is wrong to speak of one and ignore the others. In a patient I am now observing all these morbid conditions and their close relations are quite clear. A short while ago I read a paper before the Chicago Laryngological Society, in which I spoke of this matter. In this case the two nostrils are not equally wide. From the left one, which is very wide, I have constantly to remove accumulation of crusts, while in the other nostril a big ridge is present, which I think is responsible for the comparatively moist condition and the little accumulation of crusts in that side. He has one-sided ozena, dry pharyngitis and pachyderma of the larynx. This class of cases led Liebermann to compare the noses of patients with atrophic rhinitis and of normal patients by *measuring the skulls. A mention of that work is made in one* of the latest numbers of the *Laryngoscope.* It was proved beyond all doubt that by far the greater number of cases of atrophic rhinitis, something like 97 or 98 per cent., occur in *people with broad faces, combined with the low nose.* By "low" is meant from the forehead to the mouth. At the same time these people have a wide nose. These are the congenital cases or the inherited cases of atrophic rhinitis. They are usually combined with dry pharyngitis. The acquired forms have as yet no direct explanation. The atrophy of the turbinals, especially of the bony turbinals, shows there must be a process that causes the bone to shrink. There may be something similar to chronic osteomyelitis of other bones. Thus, it is possible that the explanation of the whole picture of atrophy of the mucous membrane of the pharynx and turbinals and turbinal bones is nothing else but the scar retraction after submucous or interosseous inflammatory processes and that the change of the epithelium is similar to the change that we found long ago in old fistulous tracts. The inflammatory processes would run their course in childhood, where we see often pus discharges from the nose.

The text-books treat these diseases as diseases of the mucous membranes of the nose and pharynx, and we all know that in atrophic or dry pharyngitis and rhinitis the subumcous tissue and even the underlying bone suffer just as much or more than the mucous membrane.

Dr. H. Stillson, Seattle, Wash.—I am very much interested in the pathology of the disease, and since Dr. Seiss has asked for a kind of experience meeting on the question of treatment, I wish to refer to a method of treatment that I advocated about 15 years ago. I wrote at that time to Dr. Bosworth and asked him if he had attempted to teach patients to cleanse the mucous membrane of the pharynx by means of the *tongue. He said he had in his experience seen very few pa*tients who were able to insert the tongue into the naso-pharynx. I wrote also to Dr. Solis-Cohen, and he said he had seen very few patients who would become able to do that, and he himself when he attempted *to do it, found it very difficult.* I have found patients able with the moistened tongue to cleanse the naso-pharynx. Then they can medicate it with the saliva or with some medicine they carry with them. They can do this without injury. I have discovered no deleterious effect from it. They can certainly cleanse the pharyngeal orifice of the Eustachian tube. They can stick the tongue into the nose, and I had one boy who could protrude the tongue entirely through the nose and wiggle it at you through the anterior orifice. My observation is that boys and ladies are able to learn this movement of the tongue much better than others. There are certain pathological conditions that render it very much more difficult, for instance, adhesions of the soft palate with the tonsils or cicatricial contraction of the pillars of the fauces. One advantage of this method is that the tongue has its own intelligence and can hunt out the little granulation tissue and confine its massage movement to the tissue that *needs it most. It is able to carry the medicine intelligently* to the granulation tissue. Along with the pharyngeal process there is a similar process along the upper wall of the soft palate. Often there will be a growth of granulations here, to which the tongue is able to carry the medicine and apply it. The tongue is able to apply massage to the posterior end of the turbinals, and in the early stage of this disease there is very often hypertrophy along with atrophy, and hypertrophic tissue may be found beside the atrophic tissue.

Dr. C. L. Richards, Fall River, Mass.—While admitting with Dr. Seiss that the dry atmosphere [illegible] found the condition to occur often in [illegible] in which the air is necessarily of [illegible] to work the threads. These people have the disease as marked as you see it anywhere, notwithstanding that for twelve months in the year they work in an atmosphere with if anything more than ordinary humidity.

Dr. C. M. Cobb, Lynn, Mass.—There are several very peculiar things in connection with atrophic conditions of the nose and pharynx. The typical atrophic pharynx is not a pharynx with the crust formation. The atrophy of the nose, if we begin with that part of it, is a very curious formation. The atrophy does not take place where the disease is. The disease and crust formation are around the middle turbinate, which is the last place to get well and the first to become affected. If I understand Dr. Freudenthal, he claimed that the air in the furnace is heated and the moisture is driven off. As I understand it, in the furnace the cold air passes over the hot iron and the temperature of the air is raised, but there is just as much moisture in the atmosphere after it is heated as before, although there is less relative humidity. Another thing is the escape of carbonic oxid from the hot iron, which may be an important point. It may be an irritant to these patients. Furthermore, in regard to irritation, it hardly seems probable that directly, or indirectly for that matter, mechanical irritation produces a disease of that kind. Mechanical irritation does not anywhere else in the body produce atrophy or an atrophic condition. For instance, a man working on the street may get thickened epidermis all over the hand, but the hand will not atrophy. The broadening of the face seems to me as much a result as it is a cause. A person who has atrophic rhinitis from childhood, or in other words, a person who has purulent rhinitis as a child, and this condition follows, may have the broad face because of the nasal disease, and then as it grows older and the bones develop the face is relatively broader. The cases often get well at that time, because the broadening of the face gives them more room to breathe, and better drainage from the sinuses. A very curious case of atrophic rhinitis occurred in my practice the other day. I saw a child 10 years of age, with none of the surroundings in which we would expect a case of atrophic rhinitis to originate. The child had atrophic rhinitis following an infantile vaginitis. The people supposed that the disease had migrated from one place to the other, and I have no doubt that it did so, with assistance, the contagion being carried from one place to the other.

Dr. Emil Mayer, New York City—As germane to the subject under discussion I would like to mention as a therapeutic hint the happy effect I have seen from the application of carbolic acid and glycerin to the pharynx, in a 12 per cent. solution.

Dr. Holmes—I would like to ask Dr. Mayer if he begins with a lower per cent.

Dr. Mayer—No. I use a 12 per cent. solution at once.

THE PRESENT STATUS OF OUR KNOWLEDGE CONCERNING THE BACTERIOLOGY AND SERUM TREATMENT OF DIPHTHERIA.*

SAMUEL E. ALLEN, M.D.

CINCINNATI, OHIO.

Although we may not consider this subject as exactly fitting for the deliberations of this Section, still diphtheria is to a certain extent a throat affection, and as such its discussion has a place here. The subject offers something a little different from the ordinary run of topics which engage our attention, and for that reason, on the advice of our Chairman, I take the liberty of introducing it here. It is not my intention to treat the subject from a practical standpoint, but rather to touch on the scientific advances which have been made by the bacteriologists and those engaged in working out the problems connected with serumtherapy. An enormous amount of work has been done and is being done along these lines, and an account of the latest theories advanced, even as imperfectly as given here, can not fail to be of some profit to us. The subject naturally divides itself into two phases: the first concerning diagnosis, and the second including the intensely interesting questions of immunity and serumtherapy. The diagnosis of diphtheria can not be considered as scientifically confirmed without the demonstration of the presence of the Klebs-Loeffler bacillus. No one is now content with a clinical diagnosis alone, because we know that other etiological factors may be concerned in the production of what is pathologically a diphtheritic membrane, for example, the material in crypts of the tonsils in lacunar tonsillitis. Baumgarten, who has studied many true diphtheritic membranes, states that in his opinion streptococci are often the cause of the membrane, and the diphtheria bacillus of the general intoxication.

At the present day, the Klebs-Loeffler bacillus has as distinct a position in the etiology of diphtheria as has the tubercle bacillus in that of tuberculosis. The recognition of the diphtheria germ, however, presents difficulties not met with in the direction of tubercle bacillus. Recognition of the tubercle bacillus is exceedingly easy. An absolutely accurate and positive determination of the diphtheria bacillus is very difficult, requiring time and considerable knowledge of bacterial technique. Under ordinary circumstances the appearance of simply stained specimens from an eight to twenty-four hour culture on Loeffler's blood-serum mixture is sufficiently accurate for practical purposes; but that we are able to recognize the bacillus positively by such simple means is far from the case. Diphtheria bacilli are no doubt definite specific organisms, but with such variations as to shape, size and arrangement, that we are almost justified in speaking of them as the group of diphtheria-producing bacilli. Let any one make fresh blood-serum cultures of the bacilli from different hygienic stations or bacteriological laboratories and he will find marked differences. Again there is a group of organisms often found in the throat and elsewhere that resembles the diphtheria group so closely as to be indistinguishable from them, and differing only in being non-pathogenic. To this group, which now includes the so-called Xerosis bacillus, the name "pseudodiphtheria" bacilli has been given. There is no absolutely reliable quick way of differentiating between them, the test of pathogenesis being the only sure one. In recent years many attempts have been made to devise quick differentiating methods. The most favorably considered is the method of double-staining devised by Neisser. The organisms are first stained with acetic acid methylene blue and then with an aqueous solution of bismarck brown. The bacilli present brown protoplasm and blue polar granules, the so-called Babes-Ernst bodies. Neisser and Fränkel claim the test to be absolutely accurate, if 9 to 24-hour-old cultures on Loeffler's blood-serum mixture, grown at a temperature between 34 C. and 35 C., never above 36 C., are used. That this method is certain is disputed by many competent observers, among them Loeffler. Up to the present day we may say that the variations of neither the true nor pseudo group have been accurately determined. As the disease presents a definite clinical picture while the organisms vary, this variation is probably due to differences in the soil. This much we can at present say of the diphtheria bacillus. It is a bacillus subject to as yet undetermined variations. It can not be absolutely differentiated from the pseudo group, except by animal experiment. In practice a reasonably accurate quick diagnosis can be made in nearly all cases. We are more likely to overlook germs when present than to err on the side of an affirmative diagnosis.

---

*Presented to the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

We now come to questions of immunity and serumtherapy. It is in the cure of diphtheria that the result of scientific research into these obscure fields has been of the greatest practical worth. Bacteriologists have been trying to work out a theory as to what happens when an animal is made immune by repeated injections of toxins, and as to the real nature and working of the substances—antitoxins—which appear in the blood of an animal so immunized. There has never been any very satisfactory theory offered as to the cause of either natural or artificial immunity until Ehrlich a few years ago formulated his very original theory. According to him, no animal can be inoculated with a bacterial disease unless it has in its body-cells a substance capable of combining with the bacterial toxins. This act of union between this substance in the cells and the toxins gives rise to the fever and other general symptoms of the disease. This substance he considers a sort of side-group in the molecules of the cell and serves to fasten the toxin, altered by the combination, in the cell. Natural immunity, while it may be due partially to phagocytosis or to the germicide properties of the alexins of Buchner, is, according to Ehrlich, in a large measure due to the absence of this side-group or side-chain of molecules, this so-called "Giftbindende Substanz." We can get at the theory best by applying it to the disease diphtheria. The organisms begin development in the throat of the patient; aside from the local inflammatory effect, virulent toxins are produced and absorbed. These toxins combine with the "Giftbindende Substanz" in the cells, and the act of combination causes such a cellular change as to produce the fever and other symptoms of diphtheria intoxication. If the toxins are produced in large amounts the reaction will be such that death results; the cells are too severely damaged to admit of further physiologic function. If, however, the poison is less in amount or the physiologic resistance of the cells relatively greater, further cellular activity is not inhibited, but the cells are stimulated and an effort is made by nature to restore the "Giftbindende Substanz" used up in combining with the toxins. Nature here, as elsewhere, in accordance with known physiologic laws, not only reproduces but overproduces the "Giftbindende Substanz" used up, and the overplus is taken up by the blood. The overplus is then available for immediate combination with the toxins, being produced from the local focus in the throat, and renders them innocuous. The disease becomes in this way self-limited and recovery takes place. The self-limitation of infectious diseases is due, according to this theory, to the overproduction and absorption into the blood of the very same cellular substance which while still in the cell allows of the general reaction of the organism to the infectious toxin. Diphtheria antitoxin is nothing but this "Giftbindende Substanz" produced in overplus and taken up by the blood. The self-limitation of an infectious disease and its cure by the injection of ready-made antitoxin are similar processes. In the first instance the antitoxin which limits the disease is produced within the patient; in the latter, the antitoxin is introduced already formed. Antitoxin is a substance normally present in the animal cells, which allows of the combination of toxin with the cells and the production of the disease, but which, when in superabundance and in the blood, there combines with the toxins, and hence renders them innocuous—a similia similibus theory of the first rank.

Such a principle of cure as this is isopathic. Medicine has invented many so-called principles of cure: the allopathic principle, where the disease is to be cured by the administration of a remedy whose physiological action is opposed to the symptoms of the disease; the etiological principle, where the remedy is directed toward the destruction of the cause of the disease and nature is left to herself after the cause is removed; and, as the latest development of our knowledge, this isopathic curative principle. The various infectious diseases can not be treated on the etiological principle, because we have found that the animal cells are more sensitive to the various disinfectants than are the cells of bacteria; hence the bacterial cells can not be killed by anything short of a quantity which would destroy the animal cell. The isopathic principle is the one from which we are to hope for a solution of the problems of infectious diseases. How often are we forced to recognize the truth that there is nothing new under the sun? Hippocrates said: "That which produces a disease also cures it."

Giftbindende Substanz—antitoxin—is not antitoxin until it gets into solution in the blood; consequently antitoxin has no effect on toxins already combined with the cells, and can do nothing toward remedying the evil effects of such combination when once formed. All antitoxin can do is to neutralize toxins before they get to the cells. Hence, the practical necessity of employing antitoxin early in the course of the disease. The process of immunizing becomes under this theory but a process of cell stimulation; the repeated and ever-increasing doses of toxins injected stimulate the cells to the overproduction of large amounts of antitoxins. For the production of the antitoxin, either that needed to limit the course of the infectious disease, or that which we desire to obtain in large amounts for serumtherapy, it can be readily understood that a nice poise between the amounts of toxins and the cellular resisting power of the animal must be maintained. Let the toxins be relatively too strong and cellular activity is stopped; let them be too slight in amount and the stimulation is not sufficient to produce any overflow into the blood. Take a disease like tuberculosis; here the toxins are so small in amount or slight in toxic effect that no antitoxins are produced, and the disease steadily progresses. Lately, Behring has been able to immunize cattle to tuberculosis by using injections of enormous amounts of tubercular toxins. From the blood of such animals he obtained an antitoxin which prevents tuberculosis in guinea-pigs. This theory of Ehrlich carries with it, of course, the idea of a direct chemical union between toxin and antitoxin. Buchner, Roux and their adherents still cling to a cellular theory of the action of antitoxin upon toxin, claiming that the agency of the living cell is a necessary factor in the action of antitoxin upon toxin.

Ehrlich's well-known experiments with the vegetable poison ricin indicate, at least, that the chemical theory is the correct one. Animals can be immunized to ricin and an antiricin serum obtained. Ricin has the property of precipitating in a peculiar manner the red blood-corpuscles of defibrinated blood. This is purely a chemical phenomenon. When ricin and antiricin are mixed in a test-tube, the mixture loses this coagulating and precipitating property. Ehrlich claims that a sort of double salt is formed by the un [illegible] antiri [illegible] this double salt not having [illegible] ricin alone. Just this sort soned, takes place when any antitoxin acts upon toxin. If toxin, in producing a disease, combines chemically with a cellular substance, then, in the cells specially affected, we should not be able to find any toxin. This point has been investigated in tetanus. Tetanus toxin affects the cell of the central nervous system. This has been proved by direct examination post-mortem. Now, when the body of an animal dead from tetanus is examined for toxin, it may be found in the blood and various organs, but not in the central nervous system. That portion affected by the poison is the only portion absolutely free from it, showing that a combination of the toxin and cellular substance must have taken place. The above theory is the latest and most generally accepted one concerning diphtheria immunity and serum-therapy.

As far as the practical results of antitoxin treatment are concerned, it is almost universally admitted that the mortality has been reduced nearly two-thirds. Cases still die, as we must expect when we consider the theory on which the action of antitoxin is based. A great point in the therapy is to employ the serum early, before damage is done, because antitoxin does not repair destruction already accomplished. Antitoxin simply neutralizes toxins produced after its introduction; repair and cure are left to nature. We may expect always to find some individuals so sensitive to the diphtheria toxin that the initial amount absorbed during the first day or so of the disease will be sufficient to cause death, and we must therefore expect a certain percentage of deaths. Another cause of failure, is the injection of too little antitoxin. At least 2000 units should be used and repeated every twelve hours if necessary. Any harm done by antitoxic serum is due entirely to outside substances in the serum, and the more carefully this is prepared, the less liability of trouble. Now-a-days we get perfectly reliable serum, and as improvements in its production and preservation are made we hear less and less of the various undesirable complications. Antitoxin as a chemically pure dry substance would be the ideal.

The immunity produced artificially by inoculation with toxins or by injection of antitoxic serum is short-lived. The "Giftbindende Substanz" in the blood, on which the immunity depends, is soon excreted and gotten rid of. Protective inoculation does not last above three or four weeks. When large doses are given, excretion is more rapid and the duration of immunity hardly as long. We are indebted to bacteriology for this new principle of cure, this *isopathic curative principle,* and from its development, if it shall stand, we are to expect great things for the future.

EPITHELIOMA.

REPORT OF TWO CASES—ONE OF SLOW AND THE OTHER OF RAPID GROWTH.

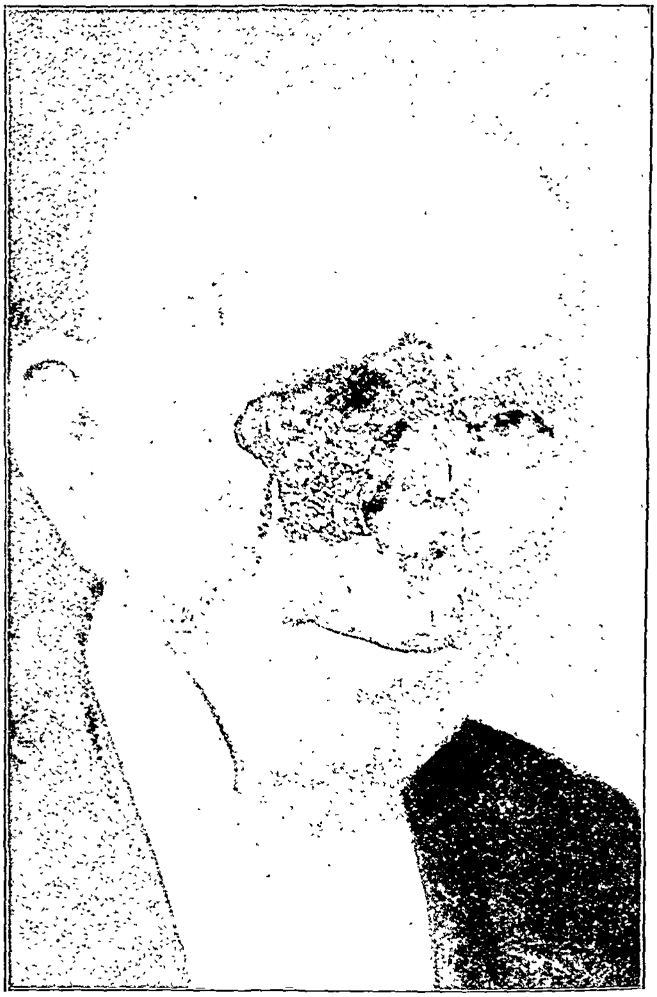
CHARLES J. WHALEN, M.D., LL.B.

CHICAGO.

The first case represented by the accompanying cuts is of especial interest, as showing how long an epithelioma may remain superficial, and it is also of some interest because of the superficial metastasis which was marked before death.

M. G., 85 years of age, widower, first consulted me May 25, 1897, desiring to be relieved of the severe pain radiating from the extensive ulceration about the right orbit, as represented in Fig. 1. The pain he described as being very severe at times and lasting in the neighborhood of sixty minutes, when it might disappear only to return again some hours later, or it might not reappear again for twenty-four or forty-eight hours.

The trouble on his face is said to have started from a scratch on the nose with a rusty nail twenty years before. The scratch never healed, but it remained very small and seemed to be stationary for a trifle over four years. At the end of that time it began to grow slightly, and up to three years before his first visit to me it had only acquired a size equal to about the diameter of a quarter of a dollar. One year before I saw him it involved the upper part of the lower eyelid. From that time until he first visited me its growth was very rapid. At my first examination, I found it had completely destroyed all the soft parts from the supraorbital ridge to a horizontal line extending 1¾ inches from the ala nasi. It had also extended across the bridge of the nose to the inner canthus of the left eye and down the nasal bones and involved all the soft parts of the nose over the right side and to within 1.25 centimeters of the ala of the nose on the left side.



The right ear began to enlarge in January, or four months before his visit to me. At first, there came a little induration directly in front of the tragus; this broke down and discharged. The ear was ulcerated upward, 4 centimeters from its lower extremity, as seen in Fig. 2; there was also considerable swelling and ulceration on the cheek directly in front of the center of the ear. A piece of the swelling of the cheek was excised for microscopic examination. The microscope showed an ill-formed epidermis with no interpapillary cones, but many embryonic ingrowths destined to form hair follicles or sweat-gland. Near the center of the epidermal part there was a cavity, projecting from the base of which into the corium is an irregular mass of cells rather lobulated, for the most part showing no basement membrane. Its lowest cells had grown down into the corium, as is characteristic of epithelioma.

December 15 the patient complained of dyspnea and claimed that the pain was much more constant and severe than at the first visit. The ulceration had progressed and had involved the left eyelid to a considerable extent. There was not much wasting and the cancer cachexia was never developed. He died Jan. 4, 1898, just twenty-one years after the first indication of the disease.

While superficial cancer of the skin is usually of exceedingly slow growth, sometimes taking years to attain any considerable size, the following case constitutes a marked exception to the rule. In June, 1896, an unmarried laborer, aged 40 years, came to the clinic of Prof. Wm. T. Belfield and myself at Policlinic Hospital. He complained of a small growth on the right side of the nose just where the nose-rest of his glasses came in contact with the skin. The tumor was nearly as large as a pea, the walls rose suddenly from the surrounding sound skin. There was very severe pain radiating from it every few minutes, although the growth was not red or inflammatory, neither was it sensitive to pressure. It was superficial and easily movable with the skin, and had the appearance of an innocent wart. The patient was positive that the first appearance of the disease was only two weeks previous to his coming to the hospital. He claimed that the tumor had been growing very rapidly the previous week and that the severity of the pain had been commensurate with the growth. Wishing to observe the case a little more carefully, he was given a mild local application and asked to return again. At his next visit, one week from the first one, the tumor was found to have increased 100 per cent. It was much more painful, but still showing no signs of inflammation.

At the request of Prof. Belfield, I removed the growth and the patient left the hospital one week later. He was free from pain, and union of the wound was perfect. Microscopic examination showed the early stage of the disease well marked. There was projection downward of cells resembling deformed interpapillary processes. The corium showed marked inflammation and numerous tubular, rounded and sebaceous gland-like growths, while infiltration of the free spaces with epithelial cells was distinct. Even below the normal epidermis in the upper reticular part of the corium, there were numerous infiltrating epithelial cells. Three years and ten months after the operation on this rapidly growing epithelioma, I met the patient accidentally, and he was enjoying the best health and the scar was perfectly smooth and healthy looking.

These seeming warts and dry fissures in people past middle life are always suspicious matters, and they are likely to escape detection previous to the moment of ulceration, when the degenerative character is impressed on the physician. If allowed to progress as in the first case, it will invariably proceed to a fatal termination. Had Case No. 1 been operated upon early, as was done with the second, the results would have been just as satisfactory and he would have avoided the awful disfigurement which annoyed him greatly during the last few years of his life.

34 Washington Street.

FACTS REGARDING CRIMINAL ABORTION.*

DENSLOW LEWIS, M.D.
Professor of Gynecology in the Chicago Policlinic; President of the Attending Staff of Cook County Hospital.
CHICAGO.

I know a man of marked erudition who wrote a book on the primitive religions. His opening paragraph is as follows: "The facts in this book are true." There is more common sense than rhetoric in this remark. We are all liable to be mistaken in our estimate of conditions. Too many statements are accepted as true simply because frequent unchallenged repetition has made us believe there is no possibility of contradiction. Continued reiteration dulls the sense of perception and discourages investigation. Moreover, social conditions change, laws become obsolete, public opinion varies and our appreciation of justice is often irrational and selfish. For this reason it is important to know the truth. In a consideration of criminal abortion no prophylaxis is consistent without a knowledge of etiology, and discussion is without profit unless the naked facts are presented.

When married women become pregnant, I estimate that 80 per cent. of them wish they were not. There rarely seems to be a convenient season for having babies. If the woman has one child she is apt to think it is too soon to have another. If she has never been pregnant, it is too soon after marriage, it interferes with a trip somewhere or some social engagement, or else she is too delicate, or her husband can not a[illegible] it. Some excuse is usually found for [illegible] act[illegible] [illegible]l in cases some attempt is made to re-establish menstruation.

---

* Read at a meeting of the [illegible]

The older ladies of the community are prolific in advice. Hot drinks, hot douches and hot baths are recommended. Violent exercise is suggested and jumping off a chair or rolling down stairs is a favorite procedure. Certain teas are given, especially an infusion of tansy and pennyroyal. Cathartics are supposed to be useful, and the different emmenagogue pills are too easily procurable. As a last resort ergot may be taken, or, if the woman is ignorant, arsenic, metallic mercury or other mineral poison may be used, often with a fatal result.

It is remarkable that among the most intelligent, refined and religious women of civilized communities a suspicion of wrong-doing is so rarely entertained. I believe this is because the idea prevails that there is no life present until the beat of the fetal heart is perceptible. The history of the earliest nations records the fact that, with the sole exception of the Jews[1], criminal abortion has always been a well-known practice. To-day it is as prevalent as ever, and the only real restraint I know of is the teaching of the Catholic church. It is improbable that any change of sentiment will occur until there develops some systematic effort to teach the truth regarding all matters connected with the reproduction of the species. Judging from my own feeble efforts in this direction,[2] a maudlin sentimentality and a narrow-minded conception of the duties and privileges of the medical profession will too often interpose objections even to the scientific consideration of these important subjects in medical societies and in medical journals. When a man like Howard A. Kelly, of Baltimore, claims that the child should be kept in ignorance of sexual matters; when he says, as he said to me at the Columbus meeting of the American Medical Association, that the discussion of the subject is attended with filth and we besmirch ourselves by discussing it in public, it is high time that our efforts began with an attempt at the education of some of the eminent members of the profession, so that they may know that there is more in gynecology than the passing of a ureteral catheter, more in the practice of medicine than the perfection of operative technique or the collection of fees.

The methods of procuring abortion recommended by the laity are usually futile. The tenacity with which the fecundated ovum clings to its attachment when once it is anchored to the uterine wall is a matter of surprise. Women have fallen from great heights and have sustained injuries sufficient to fracture limbs; they have been beaten to unconsciousness, and, indeed, have suffered even fatal traumatism without severing the connecnection between mother and child. It may be of interest for me to cite a few cases:

A woman, about seven months pregnant, fell down stairs and struck astride the edge of an upright open barrel. She complained of intense pain in the left pubic region on the least motion. Whitaker found an oblique fracture of the body of the left os pubis. There was little displacement, no lesion of the bladder or rectum, and no attempt at miscarriage. A roller bandage was applied around the pelvis, opiates were administered and the urine was drawn with a catheter for three days. In six weeks the patient could walk about the room. Normal labor occurred at term. The fracture reopened and symptoms of peritonitis presented themselves. They yielded kindly to treatment, and the patient recovered.[3]

A woman, 19 years of age, and about six months pregnant, jumped from a second story window, and immediately got up and ran away. Soon she could not walk, and was obliged to remain in bed three weeks, complaining of violent pains over the right hip. For three days after the fall she had a slight bloody flow from the vulva and complained of lumbar pains. Nothing abnormal was found on examination and the patient left the hospital in a few days without further complications.[4]

Lest it be thought that injuries of this kind are usually devoid of danger, it is proper for me to say that my records show many cases of variable traumatism, often fatal, due to falls,[5] lifting,[6] jumping,[7] crushing,[8] kicks,[9] tossing by a cow,[10] and other accidents. In one case a woman, eighty days pregnant with twins, lost one fetus as the result of a fall from a wall 10 feet high, but was safely delivered of the other at term.[11] There are also cases where very slight injury has produced abortion and sometimes the death of the mother as well, and where the simple procedures advised by the old ladies have produced disastrous results.

While walking across her bedroom in the dark a woman ran against the corner of a table, striking her abdomen, though not with any great force. She thought no more of this occurrence, but two weeks later she had an abortion, and an examination of the fetus, which was not quite four months old, showed that it had been struck upon the spine by the blow referred to. Thomas claims that this was unquestionably the cause of its death and the resulting abortion.[12]

The use of vaginal douches of hot water sometimes induces premature uterine contraction and causes abortion. In a case tried some forty-five years ago in England, in which abortion occurred in consequence of the injecting of some unknown liquid into the vagina, an acquittal was ordered by the judge on the ground that the liquid was not proved to be noxious.[13] In the United States such proof is not required. It suffices that the intent be proved, for the crime consists in the attempt and not the result. Indeed, there is still crime, even if the woman be not pregnant.

The use of alum-water injections has caused death. A woman four months pregnant was heard walking in her room and an hour afterward was found lying dead on her face, a saturated solution of alum on one side and a syringe on the other. The autopsy showed the decidua vera and placenta partially detached and small blood-clots behind them. There was no sign of contusion anywhere. It was decided that the alum solution had entered the uterine sinuses and thus by way of the venous circulation reached the heart, where more clots were found, which were deemed to have been the cause of death.[14]

The methods mentioned are usually persisted in until about the third month of pregnancy. By that time the woman is no longer in doubt as to her condition. She can no longer persuade herself that the cessation of menstruation is due to taking cold. She realizes that she is pregnant and that more effective measures are necessary at once, for she has the idea that after another month there are no means of inducing abortion without materially increasing the danger. She attempts more radical measures, or she consults her family physician, a midwife, or some physician recommended as an expert by the ladies of her acquaintance.

I can not refrain from saying in this connection that the induction of abortion is, to my mind, the most reprehensible of medical practices. I wish I could truth-fully add that none but disreputable men could be persuaded to undertake it. I know from my experience of twenty-two years as a medical man in this city and from the observation of many cases of criminal abortion in private, hospital and medicolegal practice, that the public, and many physicians as well, look upon the induction of abortion as a matter of routine. I have been told by prominent men that they expected their physicians to take care of them. I have lost the patronage of well-known society women because I refused to "help them out," as they expressed it. I have noticed that pregnancy, in some of these women, did not go on to term, and I know who is their physician now.

And yet, if I am honest, there is another aspect to this subject which can not consistently be ignored. I have seen girls of 13 well advanced in pregnancy. I remember a little one whom I saw in a maternity with which I am connected. All unconscious of any wrongdoing, she sat, with the waiting women, contentedly playing with her doll. There is something wrong with our society if such things can exist. It seems to me that one potent remedy is the instruction of children so that they may know the dangers that beset them. There is, to my mind, something lacking in the intelligence of those men who would deny to the child all knowledge of the usual consequences of sexual intercourse. It is manifestly unjust to condemn her when no attempt has ever been made to give her the slightest inkling of the truth.

The manipulations resorted to for the induction of abortion consist of the injections of liquids or the insertion of foreign bodies within the uterus with a view of exciting uterine contraction by their presence, or rupturing the membranes so as to occasion the death of the fetus or of separating fetal from maternal surface. As a matter of interest I may state that I have known women or their attendants to make use, for this purpose, of catheters, slate or lead pencils, knitting or crochet needles, glove-stretchers, hat-pins, nozzles of syringes, picture wire, hair-pins, corset bone, lemonade straws, toothpicks, pieces of chalk, tents of sea-tangle, tupelo, sponge or laminaria, as well as the direct intrauterine injections of glycerin or water, plain or variously medicated.

This is only my individual experience. Cases are recorded of the employment of the greatest variety of objects, sometimes with most serious and fatal results. The history of obstetric medicine from the earliest periods down to the present day reveals the practice of most barbarous methods, and shows most pitiable results only equaled by the traumatisms and fatalities occurring as a consequence of ignorant or unskilful attempts at delivery at term. I will not go into details regarding these practices, which Ploss has described most fully.[15] I saw one case at Biskra, in the Algerian Sahara, where a woman of the tribe of Ouled-Nail aborted following the insertion into the uterus of a sharpened piece of wood resembling a skewer. Dr. H. Smith reports to the London Obstetrical Society an instance of a woman producing abortion on herself thirty-five times by means of a knitting needle.[16]

The injuries that result from the use of these measures are necessarily varied. The average pregnant woman is ignorant of surgical procedures and the difficulty of attempts at abortion on her own person is apparent. Even in competent hands, under justifiable circumstances, the operation has not seldom proved disastrous. When the parts are diseased or structurally weakened, the induction of abortion or of labor has sometimes resulted in perforation or other injury, or has been the starting-point of a fatal infection.

Death has occurred simply from the introduction of a foreign body into the uterus. Vibert tells of a girl four and one-half months pregnant who had a canula inserted into the cervix. When the abortionist was about to inject some water the girl fell to the floor and died in a few minutes. At the autopsy all organs were found to be healthy, including the uterus, which presented only a few "fibroid bodies," not larger than a nut. Death can only be explained by a reflex action, by an "inhibition" of the nervous system provoked by irritation of the cervix.[17]

The intrauterine injection of fluids—preferably of glycerin—has of late years been recommended as a means of inducing abortion. It is said to have the advantage of causing a rapid separation of the membranes from the maternal surface and of speedily exciting uterine contractions. I have had no experience in this method of treatment, but the intrauterine injection is not devoid of danger, as numerous cases of injury clearly show. Death may occur in consequence of the entrance of air into the circulation. Martin, of Berlin, has seen two cases of this character after the use of injections, and additional cases have occurred in this country.[18] Moreover, the instrument used has caused traumatism, in one instance amounting to a perforation of the uterus and resulting in metroperitonitis and death.[19] Mercurial poisoning has also occurred from the use of bichlorid solution.[20]

When foreign bodies are used to produce abortion, especially by the woman herself, the uterus is not always entered. Thomas's case is well known. A physician's wife, thinking herself pregnant, passed an umbrella rib, not into the uterus, but to the right of the cervix, through the vaginal wall, abdominal cavity and diaphragm until it penetrated the right lung to the extent of two or three inches, in which position it was found at the autopsy. The foreign body had remained *in situ* for at least a week and it was observed that an abscess had formed in the lung tissue around the point. Abdominal section had been proposed but rejected.[21]

Javaux tells about an elastic sound which encircled the cervix and was wound around it in a knot. This sound was introduced by a midwife to induce abortion, and the desired result was obtained in two weeks. The sound, however, remained in place for two years and a half, causing abdominal pain, especially during menstruation, until it was removed with forceps.[22]

The injuries resulting from the use of catheters and other foreign bodies introduced within the uterus with criminal intent, and as a rule by the vagina, vary from a laceration to a complete internal perforation. In many instances such an injury heals without serious disturbance of the general health, unless there be infection. In the latter case, septicemia and salpingitis, often with pyosalpinx, are the usual results; but all the well-known effects of an extension of infection are possible. In my own experience I recall a case seen in consultation with the late Dr. Nesbit, of Sycamore, Ill., in which there occurred a metastatic abscess of the brain, first recognized at the autopsy, and another case, which I treated in the Presbyterian Hospital for four months, where fourteen abscesses formed in the patient's legs and arms.

The subsequent history of the foreign body is of interest. Its presence or absence is an element in the prognosis and modifies the treatment very materially. Let us consider the possibilities in detail [illegible] i of [illegible] it may perforate the uterus and pass through into the peritoneal cavity.

I had a unique case of this kind some years ago. A physician was endeavoring to produce abortion in a woman about three months pregnant, by means of a silver male catheter. The patient was nervous and had suffered from melancholia. The point of the catheter was introduced within the uterus, when suddenly the woman made a convulsive movement, and the physician, to his horror, saw the catheter disappear. When I was called to the patient, some hours afterward, I recognized a uterine perforation of the posterior wall through which I could pass a sound some 10 to 15 cm., but I could not feel the catheter within the abdominal cavity. Celiotomy was performed, but nothing was discovered in the pelvis. Finally the intestines were brought out of the abdominal cavity and after some little search I found the catheter under the liver and removed it. The uterine wound was closed with three sero-serous sutures and the right tube and ovary were removed, for it was noticed they were diseased. The patient made an uneventful recovery, and some six months later, after a normal labor, was delivered of a child, which is now 11 years old.

Dr. Gill Wylie reports a case presenting certain points in common with mine. A girl inserted a glass rod into the uterus. It slipped beyond her reach, probably perforating the uterus. The following day the girl went to her work as typewriter. Some five weeks afterward she aborted, and about two weeks after that time a tumor, the size of an egg, was felt in the left ovarian region. Celiotomy showed adhesions about the uterus and left ovary. This ovary and tube was removed, as well as the glass rod which was found near the left kidney. No point of perforation was found. The patient made a good recovery.[23]

Dr. Hektoen has on two occasions, at post-mortem examinations, found perforations of the uterus, made during attempts at criminal abortion; in one instance he found a catheter under the liver.[24]

A case is reported where at the autopsy of a young woman who died when three or four months pregnant, an irregularly-shaped hole was seen in the posterior wall of the uterus, and directly behind it, lying transversely in the pelvic cavity, was found a sea-tangle or laminaria tent about the size of a thumb. Death was due to septic peritonitis, the result of a criminal abortion. It is probable the tent was inserted in the uterus and afterward an attempt was made to remove it. One end of the tent was split and showed marks of forceps teeth or something of the kind and the string was gone. It is probable the operator became frightened and made a desperate effort to get hold of the tent with the forceps and in so doing he forced it through the uterine wall.[25]

In August, 1892, I saw Wertheim perform a Cesarean section in Schauta's clinic at Vienna. The omentum, if I remember correctly, was to some extent adherent to the parietal peritoneum. At all events, it was injected and showed evidence of inflammation, but the most curious circumstance in connection with this case, which, by the way, was operated on in strict accordance with Sanger's directions and resulted successfully for both mother and child, was a large needle about 7 cm. long, which was found imbedded in the omentum. It is hardly possible a needle of this size could have wandered into this curious location. It seems to me probable that it had entered the peritoneal cavity by way of the vagina in an attempt at an interruption of pregnancy.

Then the foreign body may remain in the uterus, causing various sequelæ in consequence of its presence, sometimes without producing abortion. I instance a few cases.

A woman at the Hospital St. Louis, in Paris, was admitted with hectic fever and dull pains in the loins and hypogastrium. A hard, irregular tumor filled the pelvis and extended into the right iliac fossa. A wooden spit 12 cm. long was removed from the uterus, where it had remained since an abortion produced by it two years previously.[26] This woman gradually recovered.

There is a case of an operation for sinus of six months' standing situated over the sacrum. The following day pus escaped from the vagina and a foreign body was felt partly in the vagina and partly in the uterus. It was a bougie over 5 inches long and had been introduced eleven months previously, abortion following in two days.[27]

Sometimes the foreign body which has produced the abortion remains within the uterus for a variable period, without appreciable inconvenience. Bunge speaks of a needle being pushed into the internal os and remaining there twelve days after the abortion.[28]

Occasionally the foreign body, retained within the uterus for a considerable length of time, becomes the starting-point for a suppurative process, through the agency of which it is expelled into the adjoining viscera or penetrates the neighboring tissues. I will speak of two cases of this kind.

A seton needle was introduced into the uterus of a young girl for criminal purposes. A three months' fetus was wounded by the instrument and expelled. Two days afterward the secundines followed but the needle remained *in utero.* About a month afterward an abscess formed in the inguinal region, accompanied by severe pain. On the seventy-fifth day the needle, six inches long, appeared at the surface.[29]

A woman used a branch of a tree to penetrate the uterus. She pushed it in so firmly that it became imbedded in the region of the kidney. The twig, which was six inches long and as thick as a goose quill, remained in the pelvis five months without the patient's knowledge and finally penetrated the rectum.[30]

A case is reported of fatal injury of the internal iliac artery. A woman, six months pregnant, consulted a charlatan, who performed an operation, which at the end of twelve hours was followed by the death of the patient and brought the man into custody. The autopsy showed an enormous quantity of blood, partly coagulated, in the abdominal cavity. The posterior wall of the uterus showed an opening of the diameter of an ordinary sound extending to the right iliac artery, which was itself perforated a little below its origin. Three other punctures had their starting-point in the cervix. In spite of these punctures the fetus had not been reached, the membranes remained intact.[31]

The cases I have cited are exceptional. The usual history is different. There occurs a death, under suspicious circumstances, of a woman suspected to be pregnant. An autopsy is held, resulting in the discovery of lesions due to violence and the presence of sepsis as the determining cause of death. There are many cases of this character recorded in medical literature. Tardieu especially has fully described them.[32]

Evidences of injury are usually found in the wall of the uterus, and consist of lacerations varying in extent from an abrasion to a perforation. The cervix may be bruised and gangrenous inflammation, diphtheric patches or diversified signs of infection may be noticed.[33] Often the fetus will be found enveloped in its membranes, which may be intact and free from inflammation. The woman in such a case will have died in consequence of an unsuccessful attempt at abortion.

When there is a trial in criminal abortion cases the defense is apt to be an attempt to demonstrate the occurrence of the lesions from external violence, such as a fall or shock, or the assertion that the injuries found are due to disease. Such a defense is, as a rule, easily disproved. A uterus in the early months of pregnancy can not be injured by a contusion severe enough to determine a serious inflammation nor a disorganization of the muscular tissue.

Of course, it is known, as Barnes has pointed out, that the non-pregnant uterus may burst and that rupture may occur at any period of gestation independent of labor. In the former case there is disease of its tissues or there is a closing of the os and an accumulation of fluid in the cavity. During pregnancy, when rupture occurs, independent of trauma, the uterus may have been the subject of Cesarean section or the seat of tubercular degeneration. Cases of spontaneous rupture, or rupture occurring after a long walk, severe vomiting or other apparently trivial cause, are recorded as early as the third month.

In spite of these rarities of obstetric practice, the medical expert will have but little difficulty, as a rule, in determining the probabilities. A microscopic examination of the uterine tissues at the seat of the lesion will be of value, for if no evidence of disease is found the presumption of an external agency will be strengthened. An ordinary abortion does not produce rupture of the uterus nor other extensive or serious lesions. Moreover, the character of the lesion, the appearance of the perforation, if there be such an injury, the color and condition of its borders, the consistency of the neighboring parts—all these will indicate whether the solution of continuity is recent or not, and will assist, in connection with the other pathologic conditions observed, in arriving at a definite conclusion.

I must call attention to two curious cases where women produced abortion on themselves by forcing respectively a hairpin and a knitting-needle into the uterus through the abdominal wall. In the first case a young girl was delivered of a dead infant at term. After she left the hospital it was learned that she had driven a long hairpin through her navel to a great depth with the avowed intention of destroying the child. She had suffered great pain afterward, which she concealed. It was noticed that some pus issued from her umbilicus after delivery, but this discharge gradually ceased and the patient left the hospital in good condition.[33]

Duncan relates the other case. A girl six months pregnant tried to produce an abortion by thrusting a knitting-needle through the vagina into the uterus. Failing in this attempt, she forced the needle through her umbilicus. Two days later abdominal section was performed and the tip of the needle was seen projecting from the fundus uteri. It was seized with forceps and removed, a stitch being inserted in the uterine puncture, as there was some hemorrhage. Two days later the patient miscarried and a black spot was seen on the child's buttocks where apparently the needle had penetrated. The mother recovered.[34]

The facts regarding criminal abortions are not fully stated without reference to the remote effects occasioned by repeated attempts—often successful—at an interruption of pregnancy. A few days ago I met a robust married woman who told me she had had eleven abortions induced by her family physician during the past six years. She appeared to be well, and perhaps she was. Most women live through the ordeal, or our graveyards would be full to overflowing. The etiologic relationship of criminal abortion to new-growths and degenerative changes has not been fully determined. The connection between many diseased states of the nervous system is well recognized, but not very satisfactorily explained. At the same time it is certain that induced abortion is often the cause of some infection with all that the word implies. In addition to the sequelæ of direct and indirect traumatism, already referred to, it is known that there often results some condition which makes pregnancy impossible. The sterility of prostitutes, remarked by Parent-Duchatelet, is estimated by Fritsch at three-fifths of all such women. Among other women who have suffered abortion during the early years of their married life, it is often observed that pregnancy is impossible when the time comes for a child to be most ardently desired. Pitiable, indeed, is the condition of such a woman. Regrets are useless now. There is only remorse and perhaps indignation tnat the medical men who, in her youth, acceded to her request, had not the manhood to tell her of her folly and to warn her of her danger.

Disinfectant for Instruments.

℞.	Olei olivæ	ʒvi	24
	Liquoris potassæ	ʒvii	28
	Alcoholis	ʒxxx	120
	Aquæ destil	ʒxvii	68

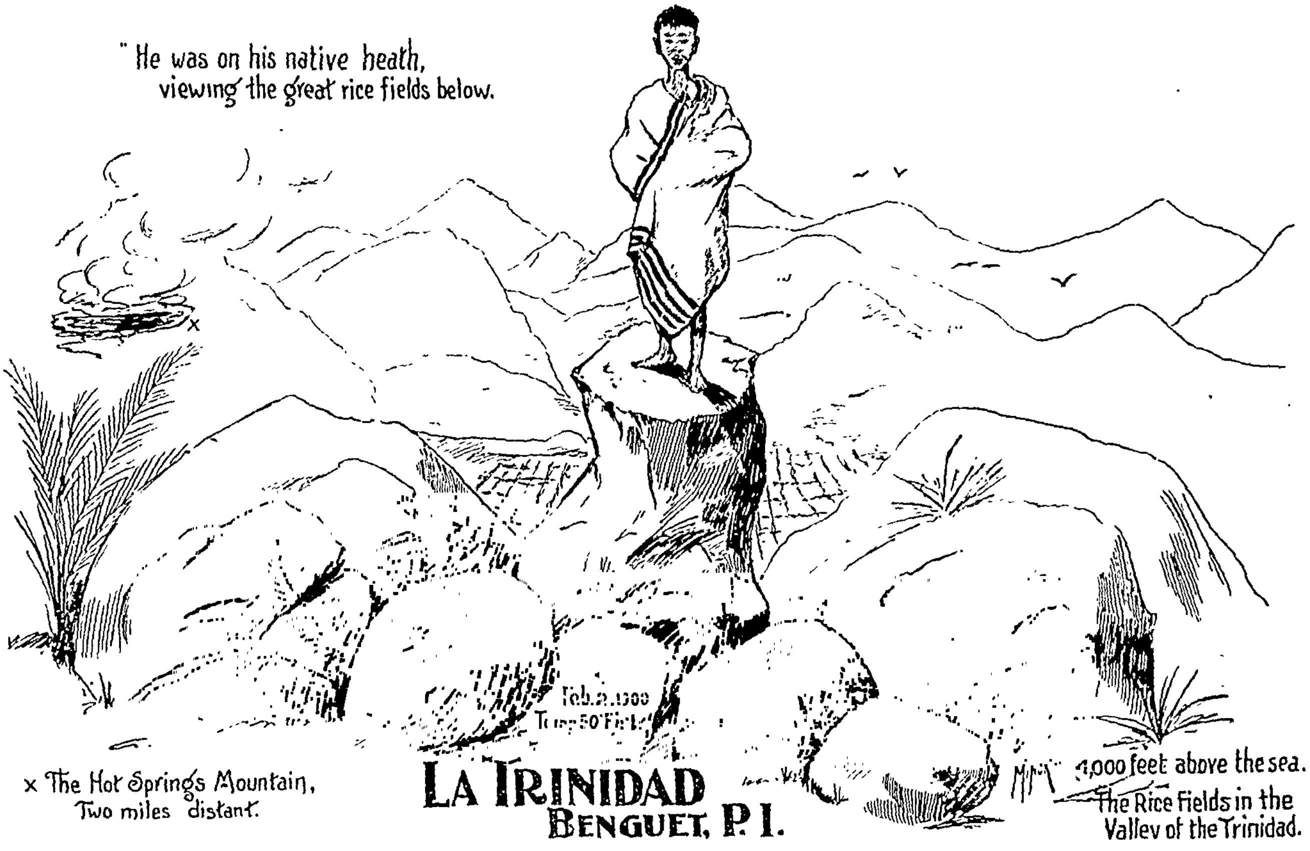
M. Sig. Wash the instruments thoroughly or wrap them in cotton saturated with the disinfectant.

Dr. Karl Gilson, in *Deutsche Med. Ztft.*, gives the above formula for a rapid method of sterilizing instruments, and states that the hands of the operator and skin of the patient may be disinfected with the same agent. The solution has no effect on the instruments. —*Jour. Surg. Tech.*

THE HEALTH AND WEALTH OF BENGUET PROVINCE, P. I.

CAPT. J. C. MINOR, M.D.
Assistant-Surgeon 29th U. S. Vol. Infantry.
ROMBLON, ROMBLON ISLAND, P. I.

To feel your feet slipping over pine logs in the Philippines and to actually lie down under tall pines and cedars by a rushing, sparkling stream of cold mountain water after a hard day's "hike" through mountains covered with hemp, banana, cocoa-nut, molava, narra and other foreign growths, poetic and useful enough in their place, is to the American soldier like being transported by a miracle from a foreign land to the home of his youth. Such were the nostalgic prodromata noticeable February 1, after marching twenty-four hours over the steepest of most dangerous trails from the China Sea to the mountain side overlooking the little valley of La Trinidad, Province of Benguet. Trinidad is 4000 feet above sea-level, with its protecting circular crest or crown of little mountains enclosing the valley that was once upon a time furiously pouring forth molten lava, but now a most beautiful green plain of some three thousand acres, watered lavishly by the Trinidad river. As we viewed the gorgeous panorama the river appeared to disappear, and so it did, for we learned later that at the northeast corner of the valley the river has tunneled its way through the mountain, to reappear on the east side, water "the great rice fields," and then wend its way westward to the China Sea. The balmy, refreshing air, the homelike odor of pine and cedar, together with the delicious water, present to the doctor but one idea, "What an ideal health resort!"



" He was on his native heath,
viewing the great rice fields below.

Two miles distant.
LA TRINIDAD
BENGUET, P. I.
4,000 feet above the sea.
The Rice Fields in the
Valley of the Trinidad.

Approximately 4000 feet above the sea in this wonderland of mineral and vegetation, there flows in torrents an inexhaustible supply of hot and cold waters. During three months field-service in the vicinity of Trinidad, I was enabled to learn much concerning the customs of the people, the salubrity of the climate, and the value of these waters. Having resided in Hot Springs, Ark., for the past twelve years, I am naturally interested in the subject of hydrotherapy.

Benguet Province is principally peopled by Igarrotes. There are two classes of the natives: the friendly Igarrote and those who are cannibalistic in their tastes, who do not hesitate to roast, broil or fricassee a white wanderer who may chance to come their way. My therapeutic information, it is needless to say, has been obtained through the other class of Igarrote.

I learned that the springs exhibit a degree of heat from lukewarm to 200 F. There is no variation, however, during the year in the springs themselves, as to either volume or temperature. Nearly all the hot springs contain sulphur, some in small quantity, others in excess. Some of the springs contain calcium hydrate, iron, potash, etc. One which particularly interested me was of water very similar to that of the Arkansas springs, being almost free—apparently—from mineral, but hot and sparkling with carbonic acid gas; it is very palatable, and a favorite with the natives in treatment of rheumatic affections and diseases of the digestive organs.

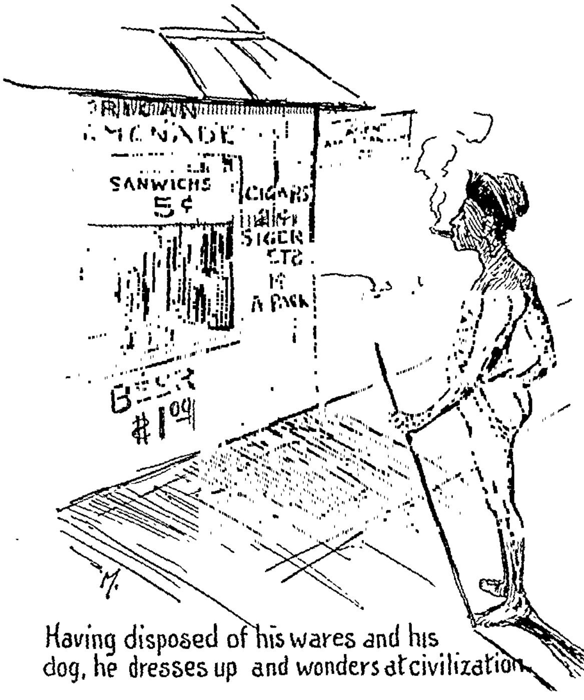
Few of this hardy athletic race are ever afflicted with disease of any kind, but when one is stricken with rheumatism, diarrhea, or a skin affection, he calls the dogs and starts for the great springs. I say "calls the dogs" pointedly, for the "dog" is the favored food of the Igarrote, and although I have not tasted of their pot of "stewed dog and rice," I am constrained to admit that when one has "hiked" in the mountains for several days successively on a meager ration of bacon and "hard tack" the odor of the native dish appears *"muy savoroso."*

The hot waters of Benguet are famed throughout the Philippine group, and all the prominent Filipinos are aware of their virtues, but the great difficulty at present is to reach them. They are distant from Manila about 250 miles north.

Syphilis is a disease unknown among the Igarrotes. Tuberculosis, heart troubles, rheumatism, and dermal diseases are those met with most frequently, but none of them is common.

It is a noticeable fact that these people are finely built specimens of brawn, erect and athletic, larger than the Filipinos, much larger than the Negrito, and very like the original North American Indian. They are peaceful and of a jovial temperament, not lazy, but usually employed either in the construction of ingenious rice dykes for irrigation, in making rattan wares, cotton goods, etc., for coast markets, in washing for gold, silver and copper, in transporting freight in their ingeniously contrived packs, or on their truck farms, growing coffee, chocolate, tobacco, sweet potatoes, Irish potatoes, beans, cabbage, lettuce, onions, etc.

When he starts for the market 50 miles distant, with his cavan of rice, one dog is sufficient.



Having disposed of his wares and his dog, he dresses up and wonders at civilization.

The reported virtue of these people accounts doubtless for the absence of venereal disease among them. The custom of mating their children by agreement at an early age exists among them; they allow the little couple to play together, to work together until they reach the age of puberty, at which time, if all parties agree, a day is set for the marriage feast. The ceremony is unique and somewhat similar to that of the Negritos—the aborigines. The bride is taken off by her father or guardian to a certain distance in the mountains, and at a given signal the groom is turned loose to hunt her up. When he spies her, she gives him the chase of his life—so to speak—and when he catches her, he leads her in triumph to the parents. The parents repeat a ceremony of gibberish, all of which is terminated by bumping together the heads of the happy contracting parties. Then comes the feast and the dance. Little or nothing, apparently is in the way among the Igarrotes to prevent rape, that is, little or nothing of clothing. The male Igarrote is in full-dress when attired in a "G" string and a "bolo." The female milks the cow and attends the ball in no more elaborate a costume than a striped native fabric recklessly thrown around her nether portions, and skillfully fastened at the waist by tucking in the ends, presenting an appearance to the American eye far more picturesque than conventional. And yet no one has ever been able to report or attribute to these people the slightest infraction of the laws of decency or modesty, and, as I say, no case of rape has ever been heard of among them, except as committed by their late rulers, the Spaniards.

Taking all other points in connection with the altitude, the delightful bracing atmosphere—temperature never above 80 F.—the delicious drinking water, the valuable mineral and hot waters, the gorgeous scenery, the abundant products of the soil, the grazing and fine cattle, the unexcelled forestry, rich minerals—gold, silver, copper and coal—and the possibility of American enterprise opening the travel way from Manila, it takes no enthusiast to believe that some day in the near future invalids and prospectors from the world abroad will be seeking the comforting and benign influences of nature's wealth in La Trinidad de Benguet.

[A railroad is already projected into the Benguet region which bids fair to become the hill sanitarium of the Philippines; indeed, there is said to be some talk of removing the civil and military headquarters to that region. If the favorable reports concerning the district are confirmed they will probably attract a very considerable immigration, and be of material aid in developing it in other respects. It is only 161 miles by the projected railway from Manila, or about the distance between New York and Albany.]

Board of Health Must Itself Act on Nuisances.—The State Board of Health of Pennsylvania is given authority, in places where there are no local boards of health, and in cases where boards of health or health officers exist, but the sanitary laws or regulations are not enforced, to order nuisances or the cause of any special disease or mortality to be abated and removed, and to enforce quarantine regulations, as it shall direct. But this, the Supreme Court of Pennsylvania holds, in the case of Commonwealth vs. Yost, does not empower it to transfer to its secretary the authority to act for it and in its stead in such matters. The court holds that, without formal action by the board, directing a nuisance, or the cause of any special disease or mortality, to be abated and removed, its secretary can neither speak nor act for it in ordering the abatement and removal of the nuisance, and the disregard of an order so given is not indictable. In other words, in the absence of any action by the board as to a particular nuisance complained of, the supreme court says that it can not agree with the contention that, because the duties of the secretary are defined by the by-laws and r [illegible] ns [illegible] board. "he speaks for, acts for and virtuall [illegible] " in or [illegible] th batement r moval [illegible] ame of

CELLULITIS SUCCEEDING CONTUSION OF LEG—EXTENSIVE SLOUGHING—SKIN GRAFTING—RECOVERY.

HENRY W. SAWTELLE, M.D.
SURGEON U. S. MARINE-HOSPITAL SERVICE.
CHICAGO.

This lesion occurred in a seaman, aged 24, native of Denmark, who was admitted to the U. S. Marine-Hospital, Chicago, August 22, 1899.

The patient gave a history of having had chills and fever while serving in the Spanish-American war, and presented a malarial cachexia.

The day before admission he was struck on the inner side of the left leg by a piece of lumber, producing a slight abrasion of the skin. The following night, and again the next day, he had a severe chill, followed by fever—39 C.—and intense headache. On examination, no bad effects were apparent, excepting a slight contusion at the point of injury; a continuous high temperature and accelerated pulse led to the suspicion of pus infection, which subsequently proved to be the case.

The patient soon complained of pain, and the examination showed indications of the infective process. A free incision was made in the midle of the leg, evacuating a large amount of pus; but unfortunately no examination was made with a view to determining the character of the pus germ, though from the previous history of the patient the plasmodium malariæ undoubtedly was an important etiological factor in the case. Two days later another incision was made near the tendo Achillis and a drainage-tube carried through to the first incision, establishing free drainage, and the limb was immersed in a 1 to 2000 bichlorid solution.

Despite careful antiseptic treatment, the wound during the following eight days underwent extensive sloughing, which required the removal of a large area of skin and subcutaneous tissue.

Several sinuses in the popliteal space and lower portion of the leg were laid open, and as soon as the wound appeared to be in the proper condition, skin grafting was commenced by Thiersch's method. After several attempts the grafts became firmly imbedded, and a month later, almost the entire granulating area was covered, with the exception of a small spot on the lower portion, and another in the popliteal space, which remained unhealed.

These continued to improve gradually however, and on May 30, 1900, the process of repair being complete, the patient was discharged. The accompanying photograph shows the extent of surface grafted.

The lowered condition of the constitution, which required systemic nutrition from the first, and the extent of the destructive process following a slight contusion, are the chief features of interest in the history of the patient.

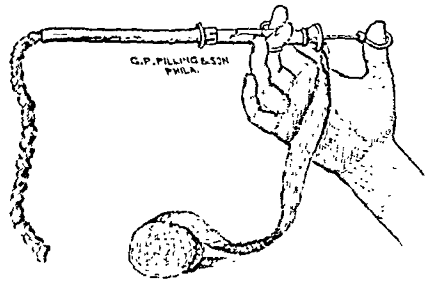
New Instruments.

The Darmack Surgical Dressing Packer.

A. GEO. BAKER, M.D.
PHILADELPHIA.

This instrument is used to pack cavities, such as gun-shot wounds, stab wounds, fistulas, sinuses, the uterus, vagina, nares, rectum, etc. It carries the gauze where it is desired and packs tightly or loosely, as is necessary.

The instrument is in the shape of a tube with a piston inside. The front end of this piston or push-rod is bifurcated, pushing the gauze forward, and when the piston is drawn back two small hooks attached to the inside and toward the far end of the tube keep the gauze from coming back. There are three rings, two on the sides of the tube and one at the near end of the rod, or piston. The thumb is placed into this last, and the fore and middle fingers in the rings on the sides of the tube. There are five sizes, varying from six to twelve inches in length and from five-thirty-seconds to five-sixteenths of an inch in external diameter. The gauze to be used is in long strips, kept in jars or done up in rolls of different widths from one-half inch to six inches wide and from five to twenty yards in length. The packer was made for me by Geo. P. Pilling & Son, Philadelphia.



Modified Goodell Dilator.

CHARLES F. SPANGLER, M.D.
KANE, PA.

The accompanying illustration is a modification of the Goodell dilator. This is designed chiefly for office work, and can be conveniently manipulated through an ordinary speculum without an assistant or an anesthetic. It is neat in construction, light in weight and embodies sufficient strength. It is evenly balanced and can be poised and directed with accuracy with the fingers of one hand while the other is engaged with the tenaculum. The blades are smooth, delicately curved, permitting a ready introduction and secure a dilatation of ⅞ of an inch. The body and handles occupy 50 per cent. less space than the original instrument. The degree of dilatation is ample for correcting constrictions of the cervical canal to facilitate medication of the endometrium, or for the use of the ordinary sized curettes; and precludes the danger of unnecessary tearing of the tissues of the cervix, always incident to the use of the larger instruments.

THE OCCURRENCE AND IMPORTANCE OF EOSINOPHILE CELLS IN THE BLOOD.

The literature contains many and contradictory statements in regard to the occurrence and the diagnostic value of the eosinophile cells. These cells are easily recognized because of the affinity of their protoplasmic granules for eosin and other acid stains; the staining methods are simple. In order to reach a definite opinion in regard to these cells, the numerous, irreconcilable hypotheses now in vogue must be overthrown so that further investigation may rest on well-established facts. Alfred Wolff[1] has made a beginning in this work, and on account of the increasing importance of hematology in clinical medicine a brief review of his results may be helpful.

Numerous differential leucocytic counts show that in normal blood the percentage of eosinophiles varies from 1.5 to 2.5; 6 to 8 per cent. is surely pathologic. Excluding leukemia, there is a large number of diseases—cutaneous, nervous, respiratory, genito-urinary, and parasitic (trichinosis)—in which an increase of eosinophiles has been claimed. In a very few of these diseases is the increase constant. Wolff details an instance of asthma in which the eosinophiles made up about 10 per cent. of the leucocytes, and this during the intervals between the attacks as well as during the latter. The sputum contained innumerable eosinophiles during the attacks. In another case of asthma the eosinophiles reached the high percentage of 15 to 39 per cent. Wolff found eosinophiles in two cases of hay-fever. This phase of eosinophilia could be studied well in the United States because of the great frequency of the disease here. In trichinosis there is such a marked eosinophilia, first shown by Brown, as to be of diagnostic value. In other forms of helminthiasis the relations of the eosinophiles have not been studied. Gonorrheal pus is often rich in eosinophiles. Wolff found the pus of acute and chronic gonorrhea to contain a varying number of eosinophile cells, the number of which in the blood may be increased at the same time, but this is not constant and without diagnostic significance.

The presence of eosinophile cells in the blood of so many animals, and in about the same proportion as in men, points to their having a distinct function in physiologic as well as pathologic conditions, but the nature of their functions has not been established. The views of the authors on this point vary so greatly that it is hardly worth the while to catalogue the various theories advanced. Except in bronchial asthma, Wolff concludes that eosinophilia has but little significance, which is contrary to the views of Neusser and others. We would mention trichinosis as a second disease in which eosinophilia is of distinct diagnostic value.

As to the origin of these cells, the view generally accepted is Ehrlich's, who traces them to the bone-marrow.

In his extensive "Studies in Leukemia,"[2] Taylor discusses fully the questions of the nature, origin, and evolution of the leucocytes, including the eosinophiles. The theories of hemogenesis are many, and often more or less speculative, so that in reality but few merit serious consideration. According to Taylor's summary, there are in the circulating human blood at least six distinct types of white cells: the large lymphocyte, and its direct descendant, the small lymphocyte, derived from the lymph-glands and nodes; the non-granular, large mononuclear leucocyte, which probably comes from the bone-marrow; the polymorphonuclear neutrophile leucocyte, derived from the myelocyte; the polymorphonuclear eosinophile, also produced in the marrow; and the polymorphonuclear basophile, again of marrow origin. The best evidence at hand indicates that these types are distinct and not interchangeable. The attractive and on the whole simple schematic division of Uskow and others, who teach that all leucocytes pass through the same developmental cycles and may be grouped as young, mature, and old cells, is not sufficient by long odds to explain the morphologic differences of the nuclei, the varying amount and kind of protoplasm and its characteristic granulations, the differences in the motility, and in the behavior under normal and abnormal conditions of the various leucocytes.

THE ETIOLOGY AND PREVENTION OF SCURVY.

Although it is generally recognized that scurvy is due to absence from the food of certain substances, the exact nature of these has not been determined, and it must be admitted that empiricism has here advanced beyond science in the prophylaxis. In adults the disorder usually develops when the diet is deficient in fresh vegetables and fruits, while it has been observed in infants nourished with artificial food or with sterilized milk. In either instance the affection readily yields to the employment of appropriate corrective measures, namely, the administration of a properly arranged dietary or of lime-juice, orange-juice, or beef-juice. In view of these facts, Corlette[1] suggests that the defaulting agent is citric acid, which is a normal constituent of fresh milk in the form of the calcium-salt, together with a small amount of potassium and magnesium citrate. Calcium citrate appears in both an amorphous nd a crystalline form, the former being convertible by oiling into the latter. The salt is more soluble in cold an in boiling water, and the amorphous variety is ore soluble than the crystalline. There is, further, ood reason for believing that the organic acid of milk present in the form of calcium citrate, almost to the oint of saturation. Now, as a result of the boiling racticed in process of sterilization, the amorphous is onverted into the crystalline calcium citrate, and this precipitated as the process is continued. In this way child nourished with sterilized milk may fail to re-eive an adequate supply of citric acid, and scurvy will esult if it be due to such a deficiency. Scurvy, it has een observed, does not occur so readily, if at all, in hildren that receive merely Pasteurized milk, and this act may be due to the circumstance that the milk is ot subjected for so long a time to so high a temperature nd that it is subsequently cooled.

---

[1] Ziegler's Beitr., 1900, xxviii, 150-178.

[2] Contributions from "the William Pepper Laboratory of Clinical Medicine." 1900; 148-328.

[1] Brit. Med. Jour., Sept. 1, 1900, p. 573.

The practical deduction from the foregoing consid-rations is that for the prevention of scurvy in infants sufficient amount of fresh milk should be given. If, or special reasons, this can not be done, properly Pas-eurized milk may be employed. If it be inexpedient r impossible to give anything but boiled milk, lime-uice or a citrate should be administered contempora-eously, using one ounce of the former or fifty or sixty rains of the latter as the equivalent of the amount ontained in three pints of fresh milk. Besides, any vater, used as a diluent, should be added to the milk, ot after, but before, boiling, in order to render the olution of citrate less, rather than more concentrated, nd thus less likely to be precipitated by boiling, which hould not be continued longer than necessary. The nilk should be permitted to cool in the vessel in which t has been boiled, and then be well stirred. The possibility is further pointed out that the crystals precipitated by boiling might be held better in suspension by the addition, before boiling, of a substance of gummy consistence, like gelatin, isinglass, dextrin or gum arabic. Also the solvent power of milk with regard to citrates might be increased by the addition, before boiling, of alkaline phosphates in the proportion of ten or fifteen grains to each pint.

In this connection it may not be uninteresting to refer to the observations of Wright[2], who reasons that scurvy is the expression of an acid intoxication, resulting from the use of food-stuffs containing an excess of mineral acids over bases, and the exclusion of those of opposite constituency. The local means of prophylaxis and treatment would, therefore, consist in the administration of salts of oxidizable organic acids, for the purpose of retaining or restoring the normal alkalinity of the blood. Accordingly, in a series of cases of scurvy in which the alkalinity of the blood was found diminished, such drugs as potassium acetate, potassium citrate, sodium acetate, sodium tartrate, sodium lactate, and sodium bicarbonate, were administered, with striking amelioration in the symptoms.

Recently Jackson and Harley[3] espoused the view that scurvy is not due to the absence from the diet of fresh vegetables or lime-juice, but rather to the eating of tainted food; but this explanation is scarcely susceptible of universal application. In opposing this view, Home[4] suggests that the process is an infectious rather than a toxic one, and that the utility of lime-juice and fresh vegetables resides in their antiseptic qualities. It will thus be seen that while we have fortunately been provided with the means of prevention and cure, we are as yet without full knowledge of the factors on which scurvy depends.

MIGRAINE WITH RECURRENT OCULOMOTOR PALSY.

The group of diseases comprehended in the designation of neuroses must be conceived to be dependent on changes in nervous structure as yet undemonstrable by present methods of investigation. There is a growing belief that aberration in function can not take place without alteration in structure—in fact, normal function must be referred to molecular changes in the cellular elements. In either instance the result is attributable to the reaction of sensitive structures to stimuli of varying degree and character. The problems opened by these and allied conceptions are almost illimitable, and we must look for their solution to the new physiological chemistry. One of the most interesting of the neuroses is migraine, which is by some considered the sensory analogue of epilepsy. Both diseases are paroxysmal or explosive, are as a rule unassociated with a gross lesion, may be preceded by an aura, be attended with hallucinations or perversions of the sensorium, or be followed by motor impairment, and are sometimes convertible the one into the other.

A number of years ago Moebius described as periodic oculomotor paralysis, a disorder attended with loss of power in the muscles supplied by the third nerve of one side, recurring at somewhat regular intervals, and subsiding spontaneously in the course of days, weeks or months. The palsy was almost always associated with headache on the affected side, as well as nausea and vomiting. Occasionally sensibility was impaired in the distribution of the ophthalmic division of the fifth nerve on the corresponding side. In some cases the paralysis was purely periodic; in others it was persistent, though with periodic exacerbations. The pathology of the affection is obscure. In some instances organic disease has been found involving the third nerve at the base of the brain; in others it must be attributed to vasomotor influences, sometimes spastic, sometimes paretic; while in still others it may be dependent upon degenerative lesions in the medulla oblongata. The disorder is progressive in course, although it may in individual instances be checked or undergo complete involution. No successful treatment is known. The disease has been designated ophthalmoplegic migraine by Charcot, but Moebius contends that it is not a true, but merely a symptomatic, migraine, probably dependent on irritation of the descending root of the fifth nerve by a hypothetic lesion in the neighborhood of the oculomotor nucleus. A case in which true migraine and recurrent oculomotor paralysis were associated has been reported by Seiffer[1] from the clinic of Prof. Jolly, of Berlin. The patient was a man, 49 years old, who presented himself on account of severe headache. His mother had been insane and his father addicted to the moderate use of alcohol. One of his children was dead of spasms and three suffered from periodically recurring headache. The patient denied a history of syphilis and of alcoholism. From the age of 8 he was at intervals of four or five weeks seized with left temporal headache lasting for two or three days, and preceded on the day before by a feeling of torpor and increased appetite. The attack was attended, besides, with anorexia, constipation, nausea, vertigo, chilliness, lachrymation, muscæ, and increased irritability. Some ten years before coming under observation ptosis of the left upper eyelid was noticed during the attack, disappearing subsequently, but increasing progressively. Two years later diplopia became an associated phenomenon. Both conditions now grew more prominent and persistent and the eyeball became deflected outward. When examined, the patient exhibited complete paralysis of all of the external and *internal ocular muscles supplied by the third nerve on* the left side, the pupils being dilated, insensitive to light, and immobile in accommodation, and the globe fixed in permanent divergence. The eye-grounds were normal and there was no other evidence of disease of the nervous system or of other viscera.

PAIN IN THE LOWER ANIMALS.

The question of pain sensations in the lower animals is manifestly difficult to study. There are those who assume that movements or reactions to external stimuli in the lower animals are the outcome of psychical processes thereby induced. They at once assume the existence of the thing to be proved, namely, the existence of psychical processes in the organisms studied. According to this view, such forms as larval crustaceans, flies, the earthworm, the moth, etc., regulate their movements by consciousness. The moth, for instance, flies into the flame because of its curiosity to see more of the strange object.

Others seek to analyze the reactions of animals on mechanical grounds. Loeb shows that the orientation of lower animals with respect to light corresponds to the same phenomena in plants toward the same source of stimulus. Hence, plants must either be "conscious" or orientation of animals is explainable on mechanical grounds as in the case of plants.

Many of the reactions in lower animals against injuries, painful in man, easily suggest that the animals actually are in pain. Touching an earthworm with a needle throws it into violent squirming, but does that squirming mean pain? When an isolated frog's muscle is placed in a strong salt solution, rapid contractions follow; surely these are not due to pain sensations. Norman's[1] experiments with the earthworm show that after cutting it in two the anterior part crawls away, while the posterior part begins to squirm. But the same thing happens on halving of the two first pieces and the pieces resulting from further halving—the anterior half crawls away, the posterior squirms. If these reactions indicate pain, then pain sensation must be attributed to pieces of the animal. The fact that the front half of any piece behaves differently from the posterior half, shows that the form of reaction in any part of an earthworm *is different on the direction of the impulse.* Forward impulses initiate orderly movements; backward impulses squirming motions. Norman shows further *that these reactions are not peculiar to this form of* injury, but result also from other local stimuli, and further that in such animals as the starfish, the leech, the crab and the honey-bee, there are no reactions observed after injury, a fact that certainly would go against the theory of pain-sensation, although perhaps not directly proving the absence of pain.

AN UNFORTUNATE DECISION.

The Appellate Court of Chicago has just given out a decision that the State Board of Health has no authority to revoke the certificate of a physician received before July 1, 1899, when the present law went into effect. We do not believe that it was the intention of the law-makers that this interpretation of the law should rule, but strict technical constructions often defeat their purpose in other matters as well as in this. *It certainly emasculates the existing law in a very* important respect, and if this decision can be taken as definitely settling the matter, the sooner it is amended by additional legislation the better, if indeed that is possible. If, however, there is a chance of a broader view in a higher court let it be taken up at the earliest practicable moment. It is a favorite dogma with lawyers that the law is the perfection of human wisdom, but from a medical and common-sense point of view we too often see judicial decisions make it the reverse.

RESTRICTION OF VICE AMONG SOLDIERS.

A contemporary in speaking of certain sanitary measures adopted in Manila, more particularly the *regulation of vice, editorially deprecates what it calls* the "attempted Puritan interference," and says "soldiers should be allowed all the liberty that is compatible with the performance of their duties, and they should be shielded as thoroughly as possible from the consequences of immorality." This does [illegible] sound [illegible] ll, to say the least; whatever grounds [illegible] ier justify such regulations, it is poor policy and worse ethics to excuse them on the ground that we should not restrict the liberties of the soldier in his tendencies to immorality, which certainly are not less than those of other men, and need in some regards even more restriction. If such regulations are employed it is better to consider them as necessitated by existing evils than as justifiable on the ground of normal personal rights. If such regulations have the results of lowering the moral standard, they do harm, for conduct in such matters will never surpass the ideal.

DISORDERS OF FAMILIAL ORIGIN.

Congenital diseases may, without being hereditary, have a familiar distribution, occurring in several members of the same generation or in collateral branches. This may be presumed to be due to some latent defect in the progenitors or to some common error in development. Diseases of the nervous system especially occur in familial distribution, as for instance, the psychoses in general, as well as the neuroses, and diseases of the brain, the medulla and the spinal cord. It has been observed that nervous diseases which may be transmitted by heredity often appear in descendants of individuals subjected to chronic intoxication. The organs of special sense and the internal viscera may be affected in a similar manner. The lesions may even be teratologic in character. Thus, twins not rarely exhibit similar deformities. An instance of familial disease of unusual character has recently been reported by Féré:[1] two neurotic women, cousins, 34 and 38 years old, respectively, presented symmetric lipomata in each plantar arch, in the one associated with tarsalgia, and in the other with herpes zoster. Inquiry failed to disclose any hereditary history of a similar lesion.

DEGREE-CONFERRING COLLEGES IN ILLINOIS.

Two years ago an attempt was made to pass a law through the legislature of Illinois limiting the degree-giving power to educational institutions possessed of a certain minimum endowment. More or less similar laws are in force in some other states and the result has been good. When the measure was before the Illinois legislature, however, there was an outcry from the secular press, that it was illiberal, aristocratic, and un-American, and it naturally failed to pass. Since then, however, the country has had an object-lesson of the need of just such a law, a need which is the greater in Illinois, since in that state charters are granted on application and any fraud can incorporate without scrutiny into its character. The exposure of the Armstrong frauds, of which there appears to be an unlimited succession, has taught the public something since 1898, and it may be that a similar measure introduced in the coming session would have better success. Such a law could not hurt existing small colleges, for no state can pass *ex-post-facto* laws, but it would prevent the outrageous frauds that are possible and legal at the present time and which have discredited Illinois degrees throughout the world. The really fraudulent incorporation can be suppressed by law, but it is useless to attempt it when a new one can immediately rise to take its place. With such an act in force, however, even the Armstrong hydra can be exterminated. It would be well if the medical profession in Illinois, and in this they would be backed by every one who possesses a respectable Illinois degree, could begin now to exert their influence for the enaction of a law similar to the Rogers act proposed two years ago. The question is out of politics and can be only actively opposed by rank demagoguery and quackery; the state has had an object-lesson of its needs, and the prospects are therefore better for its success.

MEDICAL DEFENSE IN DETROIT.

The proposed organization of physicians in Detroit, already editorially noticed in The Journal, has been perfected, we understand, without the more objectionable features heretofore referred to—the boycott and other trade-union practices. With these eliminated, there is no reason why such an organization should not be a success and of the greatest service to the profession. What medical men, in any locality, need is organization on high professional and ethical lines. This will prevent them from being exploited for the personal advantage of deadbeats in general, or of organized benefit-clubs or fraternal societies. The general public will agree with the *Detroit Free Press* when it says, "every doctor is entitled to remuneration for his services" and that he has "the further right to protect himself and the community against fraud in whatever form it may present itself." Yet, a very large portion of every extensive community has practically acted as if such rights did not exist. Matters may have been worse in this respect in Detroit than in some other localities; we do not know as to this, but they are bad enough everywhere. It may be a difficult task to educate the public out of the idea that physicians are, in a sense, public slaves and that any association for their rights is a trust, but business methods and organization will do it if anything can. There are possibly still some features of the Detroit scheme that may not be perfectly acceptable to all, but we certainly have strong hopes of good to follow its adoption and time will tell what is best to retain and what to reject. There is still another aspect than the purely business one, and one to which The Journal has often referred in the past, viz., the influence of a better medical organization in the management of public affairs as far as they touch upon the best interests of the profession. There are no men whose influence ought to go further than that of physicians whenever it is exercised for their rights, and yet it has hardly been felt heretofore in public legislation. With proper organization this will be changed, and both individually and collectively the members of the profesion will be better able to make themselves felt when matters in which their special knowledge comes into play are before the public or legislative bodies.

ADENOMA MALIGNUM.

Gynecologic literature especially contains numerous references to malignant adenoma. This might lead to the supposition that the tumor was especially common in the uterus. This is, however, far from being the case, as there is probably no glandular organ, except the kidney, in which this tumor has not been found. In the lower part of the large intestine it is quite frequent; and it occurs in the biliary ducts, the gallbladder and the liver, as well as elsewhere. The reason that it has received so much attention from the side of gynecology is probably the difficulty of its differential diagnosis from benign tumors and hyperplasias. Pathologists are agreed that by malignant adenoma is understood a tumor of glandular structure that extends into the adjacent tissues and gives rise to metastases, also often of glandular type. As pointed out by Hansemann,[1] its clinical course is that of carcinoma. Recidivations occur, ulceration takes place, its growth is unlimited, and it induces an increasing cachexia. Occasionally it happens that the metastases and recidivations present a more or less well-marked transition in their structure to cylindric and other forms of carcinoma. Hansemann describes a clear instance illustrating this course of events. It must be accepted as settled that the malignant adenoma at any time may pass into undoubted carcinoma—malignant adenoma differs from carcinoma not in kind but in degree. There is, consequently, no real reason for establishing malignant adenoma as a distinct type of tumor, as advocated recently by Selberg. Hansemann favors retaining the terms malignant or destructive adenoma, because they signify a tumor in which the glandular character is pronounced and because they carry with them the idea of smaller degrees of malignity than the term carcinoma. He, himself, however, acknowledges that there are malignant adenomas that give rise to early metastases of a typical carcinomatous structure, at the same time as there are typical carcinomas of slow growth, late metastases, and absence of return after removal. It would seem that under these circumstances a distinction was being made without any real difference. In the interests of simplicity of classification and of clearness of statement in teaching, it is indicated that a tumor which is a subordinate variety of carcinoma, structurally and clinically, be called carcinoma—adenocarcinoma. After all, there is no term that better expresses our conceptions, clinical, therapeutic and prognostic, in regard to a malignant epithelial or glandular tumor than carcinoma. Hence, carcinoma should be used in order to avoid all possible risk of misunderstanding. This is done by Cullen, in his recent work on "Cancer of the Uterus."

[1] Revue de Chirurgie, 1900, No. 8, p. 186.

A PROBLEM IN ELIMINATION.

Certain people are afflicted with what we, according to individual fancy, term lithemia, latent gout, uric-acid diathesis, uricacidemia, etc. These unfortunates complain of a number of vague symptoms, frequently of a neurasthenic character, such as muscular pains and neuralgias, disturbed sleep, susceptibility to colds and to catarrhs of the mucous membranes, headaches, and other similar symptoms. These people feel best in hot weather when perspiring freely, which naturally suggests the probability that the consequent increased elimination of waste products through the skin removes from the blood some toxic substance that is the cause of the trouble. Especially is this corroborated by the frequent observation that such people feel much worse when a cool day suddenly follows several hot ones. While *a priori* arguments are usually worse than useless, at least when applied to natural phenomena, some speculation is justified in the case of a diseased condition whose source in the intricate metabolism of the body is beyond our present reach. If increased elimination alone accounted for the amelioration of the lithemic symptoms in hot weather, it would be natural to expect that the compensatory increase in the quantity of urine on the occurrence of a cool day would automatically remove the deleterious products. Therefore we may tentatively conclude that, at least in these lithemic cases, there are certain waste products in the circulation which are readily removed by the activity of the sweat-glands, and which are not so readily eliminated even by increased activity of the kidneys. However, we must not forget the possibility that in hot days the body may find it easier to completely oxidize, rather than to eliminate, certain substances that may cause the mischief. Be that as it may, we know that the renal excreting cells possess normally a marked selective action, enabling them to remove from the blood-stream certain substances, while they compel the retention of others. Thus, for instance, all the sodium chlorid above a certain fixed ratio is promptly eliminated through the urine, while serum-albumin, which constantly passes through the cells, is not permitted to escape so long as the cells retain their full physiologic integrity. From these facts may we not suggest the possibility that in the subjects of lithemia and allied conditions there are formed certain substances that are moderate nerve and muscle poisons, for which the renal excreting cells have no selective action? May not this explain why in certain of these cases Turkish baths are vastly more efficient than diuretics? Of course this involves the assumption that the sweat-glands are more efficient in the elimination of these particular substances than are the kidneys. The practical deduction from this theorizing is that we should endeavor to aid these cases by exciting the excretive activity of the skin rather than by wasting efforts in administering diuretics. Hot baths and general massage should therefore be tried early, with the reasonable hope of relieving the autointoxication, which there is good reason to believe is the underlying cause of the unpleasant symptoms.

THE OPERATIVE TREATMENT OF PULMONARY TUBERCULOSIS.

Although we possess no therapeutic agent capable of exerting a specific curative effect on the tuberculous process, wherever situated—perhaps excepting tuberculin, and its influence for good can not always be depended on—there is not wanting evidence that recovery takes place, at least clinically, in a large proportion of cases. Such a result is brought about mainly through improvement in the [illegible] nu[illegible] state, principally by means of diet, ai[illegible] s. Inh[illegible] of compressed air [illegible] fied also been employe[illegible] ial [illegible] on the lungs. A [illegible] wa[illegible] looking to the t[illegible] means of an artificial pneumothorax with nitrogen gas, for the purpose of placing the affected tissues at rest. Following analogy, Palmer[1] recommends in the early treatment of tuberculosis of the lungs the same remedial measure that is employed in the treatment of the disease when situated in any other accessible organ, and which alone, he contends, offers a really good prospect of success, namely, surgical extirpation. In the absence of personal experience, he is compelled to base his argument on anatomic considerations, on accidents affecting the lung tissue, and on cases in which operation on the lungs has been necessary for other and graver lesions. The most important danger in connection with operations involving the lungs and pleura consists in collapse of the lung; but pleural adhesions are often present, and these will suffice to prevent collapse. Pneumothorax, however, is by no means necessarily fatal. Further, it may be averted by the formation of inflammatory adhesions, spontaneous or induced artificially; or the layers of pleura may be united by sutures; or the lungs may be kept distended by artificial inflation. A second danger to be considered is surgical emphysema, but this would not be likely to occur, as the wound-opening would be sufficiently large to permit of free movement of the air. A third danger is hemorrhage; but the superficial vessels of the lungs are not large. To avoid this complication, the affected tissues, if the lesion be circumscribed, might first be included in a ligature and then excised, or an electric écraseur might be employed. Under other conditions ligatures could be applied to the larger vessels, including the bronchial tube and its accompanying artery and vein; or the incision with the knife could be followed by the application of the electric cautery. While, theoretically, surgical treatment of pulmonary tuberculosis would seem to be an ideal method, it is not likely ever to become popular or general, as, apart from the risks and dangers of operations on the lung, it is difficult to recognize the disease when it is so circumscribed and limited as to be amenable to this form of treatment; and, besides, it will be almost impossible to exclude the presence of the disease in other portions of the same lung, in the other lung, or in other portions of the body. For certain complications of pulmonary tuberculosis, however, such as abscess or gangrene, surgery no doubt has a wider field of application.

Medical News.

CALIFORNIA.

The Redding Hospital building will be completed and ready for patients in a few days.

Scarlet fever has appeared in Santa Clara. Five cases have been reported and quarantined.

A detachment of sixteen men of the army left San Francisco, on the transport *Hancock*, October 1, to disinter and transport to this country the bodies of the men of the army and navy who have died in the Orient during the last two years.

The grand jury has been requested by President J. M. Williamson, of the San Francisco Board of Health to investigate the charges recently made that employees of the Health Department had systematically levied blackmail on the inhabitants of Chinatown on pain of persistent inspection.

Segregation of tuberculous patients in a new pavilion containing eighty beds, to be erected in the north end of the present City and County Hospital site, San Francisco, was recommended by Dr. Gustave E. Sussdorf, but could not be acted on because of the lack of the amount, $7000, necessary for its construction.

COLORADO.

Dr. Herbert A. Black, formerly of Augusta, Me., but now in practice in Pueblo, was married to Miss Bertha S. Lawrence, at Augusta, September 26.

The Pullman Company threatens not to build the contemplated shops at Denver, which will employ about 400 men, if the city council persists in passing an ordinance requiring the fumigation of all sleeping-cars upon their arrival at and departure from Denver.

An alliance, to aid the health department of Denver, is being engineered by Dr. Frank Dulin, assistant health commissioner. It is proposed to include in this combination all physicians in the city, and they will be expected to work together for the common good.

DISTRICT OF COLUMBIA.

Dr. Lincoln Johnson, Washington, has gone to the United States of Colombia, to engage in the practice of medicine.

A competitive examination was held September 24, at the Emergency Hospital, as a result of which Dr. W. R. Moulden becomes resident physician; Dr. Clifford Sperow, Martinsburg, W. Va., senior assistant, and Dr. Robert B. Beale, junior assistant.

The health officer of the District, Dr. William C. Woodward, recommends in his report, the construction of a new isolation hospital, an increase in salaries of certain officials of the department, and the control of the milk-supply of the District by proper ordinance.

FLORIDA.

Dr. Isaac Castellanos has moved with his family to Kissimmee from Havana, Cuba.

Dr. Wade H. Jones, city physician of Tampa, is reported to be ill and in a serious condition.

Dr. Urban S. Bird, Tampa, was married to Miss Laura McClellan, Warsaw, Ind., September 20.

St. Anthony's Hospital has been incorporated at Pensacola by Dr. Warren E. Anderson and others, with a capital stock of $25,000.

The Emergency Hospital, Jacksonville, which is too small and unequipped for its needs, is soon to be moved into the building, in Brooklyn, formerly occupied by the Frankie Schumaker Hospital.

Jacksonville has passed an ordinance prohibiting spitting or throwing "hulls, peelings or other litter" on sidewalks, or floors of public places on pain of the imposition of a fine of not less than $1 nor more than $5.

ILLINOIS.

Dr. Victor M. Daly, Pontiac, returned from his trip to Europe, October 1.

Dr. J. Frank Wilson and Miss Della Vandeventer, both of Versailles, were married September 30.

Rockford Hospital has received a bequest of $1000 from the estate of the late Elizabeth Hulse Moffatt.

The Moline Hospital, during the fiscal year ended June 1, admitted 135 medical, including 69 of typhoid fever, and 113 surgical cases.

Springfield Hospital reports that during its first year 122 patients were admitted, in the second year, 201, and in the third year, 341. In all, 65 have died. The hospital has a capacity of 50 beds.

---

[1] The Lancet, June 23, 1900, p. 1792.

Dr. William A. Stoker, superintendent of the Illinois Southern Hospital for the Insane at Anna, has resigned, and will become superintendent of the Southern Indiana Hospital for the Insane at Evansville.

The Cottage Hospital, Peoria, which was, if not the pioneer, one of the first hospitals of its kind in the state, is to have a new main building which will be built and equipped in accordance with modern ideas. The capacity of the group of buildings composing the hospital will be about 150 beds.

Chicago.

The Chicago Eye, Ear, Nose and Throat College has increased its capital stock from $10,000 to $25,000, and its directors from three to five.

The Medical Department of the University of Illinois, College of Physicians and Surgeons, held its opening exercises October 1. Prof. Robert H. Babcock delivered the opening address.

The Woman's Medical School of the Northwestern University opened for its thirty-first annual session, October 1. Addresses were made by Profs. William E. Schroeder and Leonard L. Skelton.

Dr. Reinard Herman, who had recently come from Germany and settled in Milwaukee, disheartened because of deferred success in practice, committed suicide in this city, October 3, by taking hydrocyanic acid.

Rush Medical College held its opening exercises in University Hall, Fine Arts Building, October 5. Prof. Llewellys F. Barker, delivered the opening address on "The Study of Anatomy." Eleven graduates received degrees.

HEALTH DEPARTMENT.

Only 398 deaths from all causes were reported to the Bureau of Vital Statistics last week as against 458 during the previous week and 455 during the corresponding week of 1899. The annual death-rate, based on this total, is 12.2 per thousand of the United States Census figures of population—the lowest October mortality-rate on record. The increase of diphtheria, scarlet fever and other contagious diseases of childhood which as a rule, follows the resumption of school attendance, is much less marked this year than usual. The Health Department attributes this chiefly to the system of medical inspection of the schools maintained by the Board of Education. Deaths from acute intestinal diseases were 54, consumption 39, pneumonia 30, heart diseases 29, nervous diseases 23, Bright's disease 21, violence—other than suicide—18, suicide 13, diphtheria 15, cancer 17, bronchitis 10, convulsions 13, apoplexy 10, typhoid fever 7, and scarlet fever 3. Births reported were 544.

INDIANA.

Dr. Charles H. Waxham, North Liberty, has given up his practice there and has gone to Denver, Col.

Seven cases of smallpox are reported in Liberty Township, Fulton County, by county physician Charles E. Gould, Rochester.

The Doctors of Lafayette are sensitive about riding in a patrol wagon and have petitioned the city council to procure a real ambulance.

The wedding of Dr. David F. Trenary, resident physician at the Asylum for the Incurable Insane at Julietta, and Miss Esther Wilcox, Indianapolis, which occurred July 11, has just been announced.

Dr. D. J. Swarts, wife and son, also physicians, of Auburn, have just returned from a lengthy sojourn among the leading medical centers of Great Britain and continent. Dr. D. J. Swarts is 70 years of age, and "still hale and hearty."

A hospital for consumptives is a crying need of Indianapolis, and Mrs. Lewis Wallace, Jr., read a paper on "The Care of Consumptives" before the Flower Mission, which has the project in charge, pleading for the speedy attainment of its desire.

The State Board of Health has prepared an address to the people of the state, warning them against smallpox, which it fears will be epidemic this winter, and containing illustrations of smallpox patients, and instructions as to vaccination, disinfection and lay recognition of the disease.

KANSAS.

Dr. Josiah P. Lewis and daughter, Topeka, received painful injuries in a runaway accident.

Dr. William H. Righter, Topeka, was charged, October 2, with having failed to report a case of smallpox.

The first smallpox case since the present crusade in Topeka commenced was sent to the isolation hospital, October 3.

Plans are now in the hands of local contractors for the erection of a large private hospital in Ellsworth to be owned and operated by Drs. Hissem and O'Donnell.

The new hospital which is to be erected in Pittsburg, at a cost of $25,000 will be under the direction of the Sisters of St. Joseph. Mr. C. J. Devlin, of Topeka, has donated the land and will defray the expense of the construction of the building.

A smallpox epidemic is to be averted in Topeka if the local board of health has its way. It has prepared an ordinance providing for compulsory vaccination and a penalty for disobedience of the order. The city physician has also sent out a circular calling attention to the ordinance regarding reports of contagious diseases and quarantine therefor.

KENTUCKY.

Dr. John P. Gilmer, Louisville, was married, October 10, to Miss Margaret Goodloe, of the same city.

Dr. J. I. Greenwell, a graduate of the Hospital School of Medicine, Louisville, has located in New Haven.

The reorganization of Speers Hospital, Dayton, is well under way. Among the new trustees are Drs. Charles B. Schoolfield and W. Dallas Richards, of Dayton. The number of trustees has been increased to five, and men have been selected who will work in harmony with the medical staff.

LOUISIANA.

The local board of health at Shreveport has been organized by Dr. James C. Egan, health officer, with Dr. Henry C. Coty as chairman.

The reproach against New Orleans in point of health is being taken away. For the eleven weeks ended September 15 the average death-rate was only 16.08 per annum per thousand for the white population.

The fruit companies of New Orleans have protested against the delay entailed by the State Board of Health, which requires that all ships on leaving Port Limon and Bocas del Toro be inspected and disinfected, and detained and again inspected before being allowed to come up to the city. The board very properly refused to consider the matter or modify its rules.

MAINE.

The school board of Rockland has been asked by the local board of health to refuse to accept the vaccination certificates of the Boston physician who issued 157 without, it is alleged, having made personal examination of the children. The school board very properly replied that it was not within its province to question the validity of certificates signed by a regular practitioner and suggested that the board of health assume the responsibility.

The Portland Board of Health's report shows that for the year ended Feb. 28, 1900, there were 887 deaths in the city. Zymotic diseases caused 11.85 per cent. of the deaths; constitutional diseases, 24.24 per cent.; local diseases, 50.51 per cent.; developmental diseases, 8.45 per cent., and violence, 4.74 per cent. Of contagious diseases, 191 cases of scarlet fever, 130 of diphtheria and 83 of typhoid fever were reported. The board urged upon the city government the necessity of municipal milk inspection, and of a new isolation hospita

MARYLAND.

Baltimore.

Dr. G. Milton Linthicum has returned from Europe.

Dr. Gordon Wilson has been appointed fellow in pathology in the Johns Hopkins University.

Dr. Charles E. Simon has returned from Nova Scotia, where he has a summer sanatorium.

Dr. H. B. Jacobs, the American secretary of the International Medical Congress, has returned from Paris.

Prof. Claribel Cone delivered the opening address at the Woman's Medical College on "Woman and Her Work."

Mrs. Florence Levy Eversman has given an additional $500 to the Hebrew Hospital, as a memorial to her parents.

Dr. John Arthur Luetscher, late interne at the Johns Hopkins Hospital, has been appointed a resident physician at the Boston City Hospital.

At the Woman's Medical College Dr. Melker Elkstromer has been elected professor of chemistry; Dr. Henry Lee Smith, associate professor of diseases of children, and Dr. Louise Erich, adjunct professor of hygiene.

Health Commissioner Bosley is determined to enforce the law prohibiting the exposure of corpses of those who died from infectious and contagious diseases, and restricting the attendance at their funerals. He regards this as a most prolific source of the spread of such diseases.

For the week ending October 6 the deaths were 192, births, 304. Of the latter 158 were males and 146 females. There were 30 deaths from tuberculosis, 18 from cholera infantum, 4 from typhoid fever, 9 from diphtheria and croup, 6 each from cancer and pneumonia, 12 from Bright's disease. New cases of infectious diseases were reported as follows: Diphtheria, 51; scarlet fever, 8; typhoid fever, 38; whooping cough, 1.

The health commissioner has issued a circular asking the co-operation of physicians in fighting diphtheria and scarlatina this fall. He urges physicians to insist that all children in families where there is diphtheria be immunized by antitoxin, when they can not be isolated. The department offers to supply the antitoxin to those too poor to purchase it. He considers that a scarlet-fever patient should be kept isolated for at least three weeks after the temperature has returned to normal. In case of diphtheria the room will be disinfected by the officials of the department, after the throats of all members of the family have been proved to be free from germs. In scarlatina, the premises will be disinfected after all desquamation has ceased, the three-weeks' limit being observed as far as possible.

MASSACHUSETTS.

The Cullis Consumptive's Home, Boston, celebrated its thirty-sixth anniversary on September 27.

More than $1200 has been raised for the Springfield Hospital by the efforts of the City Hospital Aid Association.

Licenses to practice were given to 26 out of the 33 candidates who took the examination of the State Board of Registration in Medicine at Boston on September 11 and 12.

Lynn Hospital reports receipts for the past year of $21,175 and a balance of $4036.47, which has been added to the hospital fund. The average cost of maintenance of patients was $7.69 per week.

Dr. Archibald J. Ranney, who has been connected with the State Hospital at Tewkesbury for seven years, has been appointed superintendent of the Boston Almshouse and Hospital, on Long Island.

Harvard Medical School is to have a new home. About 27 acres of land has been purchased in Brookline by a syndicate, who are to hold it in trust for the school. Early in the spring work will be begun on the physiological laboratory, for which $50,000 has been voted from the Henry L. Pierce bequest. The idea of President Eliot is to have all the departments of applied biology united in one grand school.

MICHIGAN.

Dr. F. Josephus Groner, Grand Rapids, has been appointed consulting physician at the Soldiers' Home.

Teachers throughout the state are to be furnished the "Data and Statements" of the State Board of Health, to assist them in instructing their pupils in hygiene and sanitation.

It is reported that, despite the law compelling physicians to register in the county clerk's office on penalty of fine, 55 in Macomb County alone have failed to comply with the law.

The State Board of Health has issued its 10th edition of "Instructions to Consumptives and Their Friends." It is an instructive leaflet, publishing in concise form a store of advice.

"Irregulars," numbering 114, were practicing medicine in Berrien County a year ago. Now, thanks to the new law and its enforcement by the State Board of Registration in Medicine only 15 remain, and their local professional life is likely to be very brief.

Including reports by regular observers and others typhoid fever was reported present in the state in 262 places; consumptives at 177 places; scarlet fever at 31 places; whooping cough at 24 places; cerebrospinal meningitis at 12 places, and smallpox at 4 places.

The controversy between the State Board of Health and certain Detroit physicians regarding reporting cases of tuberculosis has been passed on by the Supreme Court, which holds that there is no danger line that the courts can take judicial notice of, and that the question is one for a jury to decide. A new trial was therefore ordered.

For September, 1900, compared with the average for September in the 10 years, 1890-99, scarlet fever and typhoid fever were more prevalent; cholera infantum, measles and cholera morbus much more prevalent; diphtheria, consumption and pneumonia less prevalent, and whooping cough and remittent fever much less than usually prevalent.

Two black-lists are to be published by the Detroit Physicians' Business Association, one containing the names of those who fail to pay their physicians, and the other, the names of physicians who attend black-listed patients. For the latter crime a fine of $5 to $25 is imposed. It also proposes to promulgate a uniform fee-bill and to assess each member $1 for the family of each deceased member.

MINNESOTA.

Hamline University, medical department, held its opening exercises, October 1. Prof. Norman Dreisbach delivered the opening address.

Dr. Peter J. McCormick, Yazoo City, has brought suit against the estate of the late Capt. R. C. Shepherd, for $6000 for professional services. The executor claims that the bill is exorbitant and will contest it.

A plan of medical inspection of schools has been submitted to the Minneapolis Board of Education by Drs. Richard O. Beard and Henry M. Bracken, who urged its adoption. It contemplates the appointment, by the board, of four medical inspectors at a nominal salary, who will appoint a staff of unsalaried assistant physicians, each of whom will make a daily visit to the schools to which he is assigned, examine sick children, advise the teachers what to do, and report to the medical inspector.

MONTANA.

The health officer of Helena sent two cases of suspected smallpox to the county hospital, September 23.

Bids for constructing a twelve-room brick hospital and hospital steward's house at Fort Keogh have been secured by Col. Pond, department quartermaster. The bids on the hospital range from $23,087 to $31,917.

Smallpox is rampant in Butte. In the week ended September 24, nineteen cases were sent to the isolation hospital. The authorities have awakened from their apathy and have empowered the city physician to use his discretion regarding compulsory vaccination.

NEW YORK.

Dr. Lucian Howe, Buffalo, has returned from Europe.

A serious epidemic of diphtheria is reported from Ithaca.

The health officer of Troy reports for the month of September 33 deaths and only 13 births.

Dr. William C. Krauss, Buffalo, has been made one of the associate editors of the *Psychiatrichc Wochenschrift*, published under the direction of Dr. J. Bresler, of Freiburg (Schliesin), Germany.

Dr. Frederick A. Cook, Brooklyn, who accompanied the Belgian antarctic expedition in 1897, as surgeon, has written his experiences in a volume entitled "Through the First Antarctic Night."

On October 5 the cornerstone of a new hospital at Oneonta was laid with appropriate ceremonies. The building is to be erected and supported by Col. Reuben E. Fox, and, in memory of his wife, is to be known as the Aurelia Osborn Fox Memorial Hospital.

New York City.

The Cornell Medical School opened in its new home, October 2, and on October 5 President Schurman, of Cornell University, formally accepted the building in the name of the university.

The fiftieth anniversary of the marriage of Dr. and Mrs. R. Ogden Doremus occurred on October 1. Dr. Doremus equipped the first laboratory in this country for instruction in analytical chemistry. He has been a professor in Bellevue Hospital Medical College and in the College of the City of New York for over thirty years.

OHIO.

Dr. Charles W. McGuire, Toledo, has been appointed demonstrator in the chemical laboratory of the Toledo Medical College.

Dr. Yeatman Wardlow was married to Mrs. Lillian Beatty, widow of General Beatty, of Cincinnati, at Asheville, N. C., September 27.

Columbus.

Dr. R. H. Wilson has started for Bluefields, Nicaragua, where he has accepted a position with a rubber company.

All-night street-car service is demanded by the Columbus Academy of Medicine, which passed with but one dissenting vote, resolutions presented by Dr. William U. Cole, providing for a half-hour all-night schedule.

Dr. Robert E. Ruedy, assistant physician at the State Hospital for the Insane, has resigned and will take up practice in Cleveland. At an entertainment given in his honor, September 28, the officials and employees of the hospital presented him with a handsome chair.

At the meeting of the State Medical Board, October 3, it developed that none of the osteopaths of the state had availed themselves of the privilege accorded them by the last legislature of securing a license to practice by passing an examination. The members of the board are in doubt as to whether the osteopaths are preparing to leave the state or mean to fight the law in the courts.

The health department of Columbus has ordered that the inmates of houses of prostitution be regularly examined each week by the nearest district physician. It is thought that by thus having the members of the department assume the responsibility, the spread of venereal diseases could at least in part be prevented. As a result of the order there has already been a clash between the department and the physicians doing contract work with these houses.

Cincinnati.

Miami Medical College opened for its fall session, October 2.

Drs. Oliver P. Holt and Edward S. McKee have returned from Europe.

The Cincinnati College of Medicine and Surgery commenced its work for the college year, on October 2.

The new buildings for the City Branch Hospital for Consumptives will be ready for occupancy about Jan. 1, 1901.

The Medical College of Ohio opened for regular routine work, October 4. Prof. Phineas S. Conner and Dean Thaddeus A. Reamy welcomed the students.

At the regular monthly meeting of the board of trustees of the City Hospital, it was decided that each member of the interne staff should serve a term of six weeks at the consumptive hospital.

PENNSYLVANIA.

Dr. J. W. Worrell has moved from Brownsville to Pittsburg.

Dr. Thomas E. Roche and Miss Bridget G. Mulvihill, both of Renovo, were married, September 25.

Pittsburg has an increasing number of deaths from violence. In 1894, 290 bodies were received at the morgue; in 1895, 311; in 1896, 328; in 1897, 326; in 1898, 409; in 1899, 490, and in 1900 up to September 25, 499.

On account of the prevalence of smallpox at Erie, the public schools will not be opened for two weeks, in order to permit all the pupils to be vaccinated. There are 7 cases under quarantine, and no new cases have developed for several days.

Warrants have been issued in Pittsburg for the arrest of 419 dealers of oleomargarin. It is said that of 800 samples of butter examined, 498 were found to be oleomargarin. All told, 647 suits have been instituted. At Hollidaysburg the State Pure Food Commission has caused a number of arrests to be made for this offense. Six dealers were also placed under arrest for selling impure milk.

On October 3 a boy living at Chambersburg fell from a gate and fractured his leg. His father, it is said, picked the boy up and began singing a hymn, and did not send for a physician because he was a believer in the faith cure. A member of this sect was therefore called in and religious services were held. Subsequently the father called in a physician, who reset the bones. The district attorney has warned the father that if the boy is made a cripple or dies he will be held criminally responsible.

Dr. Henry Beates, president of the State Board of Medical Examiners of Pennsylvania, is making a thorough examination into the character of an institution which is known both as the Delaware University and University of Delaware, with headquarters located in a saloon, at Wilmington, Delaware. It is believed that the incorporators were a saloon keeper, a railroad conductor and a Doctor Foster, the latter of whom, it is said, made a thorough canvass of England and parts of Germany. England is thought to have been the first territory canvassed by this institute, but through the exposures made by certain parties they did not succeed.

Philadelphia.

The vacancy on the resident staff of the University Hospital has been filled by the appointment of Dr. Stanton.

Dr. F. X. Dercum now occupies the chair of mental and nervous diseases, and Dr. J. C. DaCosta that of surgery, in the Jefferson Medical College.

The Common Council a few days ago appropriated for the vaccinating physicians of the city the sum of $5000; and for disinfecting the schools and tanks, $2500.

The opening address at the Medico-Chirurgical College was made by Dr. Joseph McFarland, who called attention to the increased facilities offered by the laboratory recently constructed.

During the past summer a number of improvements have been made at the University Hospital. Eight new rooms have been added to the private wards, and a new medical ward for children has been established.

Through the will of Charles Edward Orme an estate valued at $50,000 has been left to the Episcopal Hospital to maintain as many free beds as the income will support, the same to be known as the "Charles Edward Orme Free Beds."

The Home of the Holy Child for Colored Children, located at 627 North Forty-third street, has been placed under strict quarantine owing to the development of diphtheria among the inmates. Six cases have so far been reported. At the present time there are 26 children in the institution.

The twelfth annual report of the Mary J. Drexel Home of the German Hospital has been made known and contains the following: Number of children cared for during the year, 415; number of house patients, 3199; number treated in the dispensary, 39,680; number of operations performed, 944.

Dr. Leo Alexandroff, who came to Philadelphia a year ago as assistant-surgeon for the Russian cruiser *Varlag*, and who decided to remain in this country, and to that end left his ship and took out his first papers, is now in the custody of the United States court, the Russian government having claimed him as a deserter.

Dr. Alfred Stille's will has been admitted to probate and bequests have been made known as follows: His medical library, manuscript, indexes of pathology and therapeutics, various medical writings and a portrait of John Hunter have been given to the College of Physicians. Various other bequests were made. The value of the estate has been placed at $80,000.

Dr. Joseph Neff, who has for some time been a member of the Board of Charities and Corrections, has tendered his resignation to Mayor Ashbridge. It was accepted, and Mr. William J. McLaughlin has been appointed in his stead. The physicians now on the Board of Charities are: Dr. John V. Shoemaker; Dr. E. R. Kirby; Dr. Albert Dingee, and Drs. C. S. Middleton (homeopath).

The lax methods by which poisonous drugs have been sold in this city for some time past has been a subject considered by the State Pharmaceutical Examining Board during the past week. A special agent has been visiting the different drug stores to determine the qualification of the clerks employed and the restrictions placed on the sale of these drugs. The poison registers of the drug stores are being looked into carefully.

The plan of work of the United Hebrew Charities is to be largely remodeled after that of Chicago and Cincinnati. By this method, instead of giving separate entertainments and donations for individual charities, the whole organization should receive donations and carry on the necessary work. The society's physicians during the year made 20,748 visits. The total receipts had been $47,238.29 and the disbursements $44,547.84.

At the University of Pennsylvania, owing to the many changes in the curriculum, the high grading, and lengthened course in the department of medicine, the number of students is reduced to a limited extent. The new schedule provides that juniors having elected the biological course may matriculate in the medical school, at the same time taking the necessary branches in the colleges. In this way they will receive the college degree and likewise will be admitted to the second year class of the medical department on completing the college course.

A movement has been set on foot at the Jefferson Medical College to establish a memorial to the late Professor Jacob M. da Costa. This idea was recommended by the faculty and was first proposed by the Hon. William Potter in his opening address to the students of the Jefferson Medical College last week. The following resolution was adopted: "Resolved, That for the purpose of commemorating the eminence of the late Professor Jacob M. Da Costa as a member of the faculty of this college, his notable career as a physician and his distinguished services to humanity and to the advancement of medical science, a laboratory of clinical medicine, to be known as the 'J. M. Da Costa Memorial Laboratory of Clinical Medicine' shall be established in connection with the Jefferson Hospital; and that the medical profession, the friends of Dr. Da Costa, and any others who may desire to contribute to the fund needed for the establishment of such laboratory shall be given the opportunity of subscribing thereto." The following committee was appointed to receive subscriptions: Simon Gratz, chairman; Judge Sulzberger, Dr. W. W. Keen, and Dr. James C. Wilson.

CANADA.

Dr. J. J. McFadden, Neepawa, Man., has been appointed superintendent of the Insane Asylum at Brandon.

Typhoid fever has been very prevalent in all parts of the city of Winnipeg, but it is now being got under control.

The Hon Dr. Sullivan is resuming lectures in surgery to Queen's medicos after an absence of one year through sickness.

The directors of the Lake of the Woods Milling Company at their annual meeting, held last week, voted $2500 to the Winnipeg General Hospital and $500 to the St. Boniface Hospital, Winnipeg.

Dr. C. J. Fagan, provincial health officer of British Columbia, is having the Indians on the local reserves vaccinated as a precautionary measure. There seems to be danger of the introduction of smallpox into Victoria.

The St. Thomas (Ont.) Medical Society is endeavoring through its members to have the rate per capita for lodge work raised, and the fraternals are threatening in their opposition to this unpopular procedure to import other physicians into that city.

Dr. Fife Fowler, who has been connected with Queen's University medical department, Kingston, for fifty years, has resigned the position of professor of the practice of medicine. Dr. James Third, late superintendent of the Kingston General Hospital, is his successor. Dr. Fowler will retain the honorable position of Dean of the Medical Faculty.

Dr. W. T. Barrett, medical superintendent of the Samaritan Hospital, Dawson City, arrived in Winnipeg Oct. 1, on his way to visit the hospitals of London and Edinburgh. He states that when he left Dawson the population of that place was more than usually healthy. There is now only one case of smallpox, and other infectious diseases are very scarce. In the doctor's opinion, the Yukon is an eminently healthy country. Dr. Barrett was for several years connected with the St. Boniface Hospital, Winnipeg.

Toronto.

The department of Dr. J. J. Mackenzie, professor of pathology in the medical department of Toronto University, is being equipped to the extent of $4000.

In the medical department of Toronto University 110 students have been enrolled in the freshman class this year as against 103 in 1899, 73 in 1898 and 61 for the term of 1897-98. Several additions have been made to the staff of demonstrators.

Queen's University may appeal to the Ontario Parliament at its next session for a grant for carrying on its work. Toronto University being the only University in the province receiving aid from the government, will necessarily look askance at such a proceeding, being also fearful that Queen's might be raised to the status of a provincial university for the eastern portion of the province.

REAMALGAMATION OF TORONTO AND TRINITY.

Sir William Meredith, the new Chancellor of Toronto University, addressing Convocation, which was held on the campus on the afternoon of Oct. 2, spoke concerning this matter. He paid a high tribute to the ability of the medical profession; and thought that while there was another teaching body in the city, they should be on good and fair terms with every school. The subject was now under discussion, and he expressed the sincere hope that some means could be devised by which the energies of the men connected with both schools may be combined for the purpose of promoting the advancement of medical education in this country.

The executive of the Ontario Consumption Association met in Toronto last week and prepared an application to the city council for $50,000 for a consumption sanatorium, to be authorized by the people at the municipal elections in January next. To show their good faith in the movement, the Association will undertake to raise $30,000 by popular subscription, the city will then provide the $50,000, which, with the offer of the treasurer of the National Association of $20,000, will make

$100,000, the amount necessary to erect and maintain an institution of 100 beds at first. A suitable site for the building, about nine miles from Toronto, has been secured.

Montreal.

Dr. Laberge, city health officer, has returned from Paris.

Dr. J. Alton Harris has returned from active service in South Africa.

The last case of smallpox has been discharged from the civic hospital.

The Medical Faculty of Bishop's College opened on October 1, with a fairly large attendance of students.

The Medical Association for St. Frances Xavier District met in Sherbrooke last week. An important question discussed was that of a medical tariff, and it was decided to publish the discussion in the Montreal and country papers, so that there might be a clear understanding between the physicians and public generally on the subject.

FOREIGN.

The library of the great chemist, Bunsen, is now being sold at Leipsic.

Lannelongue, of Paris, has been made a commander of the French Legion of Honor.

The professor of psychiatry at Jena, Dr. Ziehen, has accepted a call to the chair of psychology at Utrecht.

The friends of Senator and Busch, of Berlin, celebrated the twenty-fifth anniversary of their connection with the faculty September 14.

Another medical victim to the Swiss glaciers is Dr. Max Schaeffer, a promising young rhinologist of Bremen, who was found dead in a crevasse.

The court physician to the Ameer of Afghanistan is, or was until recently, a woman. Her name is Miss Lillias Hamilton, M.D., Brux. and London School of Med. for Women.

Yersin was awarded the Audiffred prize of 15,000 francs last spring for "his acts of devotion," and has applied the sum to the extension of his plague-serum laboratory at Nha-Trang.

Menelik, Emperor of Ethiopia, has been awarded the first prize on the list offered by the French Society against the Abuse of Tobacco, as he prohibited the use of tobacco throughout his dominions under severe penalties.

The death of Sir William Stokes in South Africa was followed in a few days by that of his talented sister, Miss Margaret Stokes, in Dublin. She was the author of several noted works on Irish ecclesiastical architecture and archeology.

The friends and admirers of Professor Potain, of Paris, propose to present him with a souvenir medal on the occasion of his retirement from the Charité next spring. Subscriptions are received by P. Masson, 120 Boulevard Saint-Germain.

The friends of Dr. Li Willems, of Hasselt, Belgium, have called upon all who profited by his discovery of preventive inoculation of pleuropneumonia in cattle to co-operate in celebrating his fiftieth professional anniversary, October 14.

The Graefe prize for the best works that appear in von Graefe's *Archiv f. Ophthalmologie* during the years 1896 to 1899, has been divided between Dr. Hess, for his work on "Accommodation," and Bernheimer, for his studies on the "Nucleus of the Motor Oculi."

El Siglo Medico announces that the Spanish government has appropriated $8000 to enlarge Dr. Cajal's laboratory at Madrid, with $4,800 annually for its maintenance and a pension of $1,600 for the distinguished scientist, on whom the Moscow prize was bestowed by the International Medical Congress.

The pilgrims constantly arriving at Rome to celebrate the "holy year" are filling the streets with beggars and the hospitals with incurables. The sanitary conditions are menaced by this state of affairs and the Italian minister of the interior has issued an order forbidding the further organization of pilgrimages composed entirely of the sick and indigent.

The new laboratories at Manguinhos, Brazil, for the production of plague serum and vaccin are completed and are models in every respect, the *Brazil Médico* asserts. The different pavilions are on separate hills, about 1500 feet apart, with the building for the horses in the valley between. The entire establishment is in charge of Prof. Pedro Affonso and Oswaldo Cruz.

The *Deutsche Med. Woch.* states that the calendar published by the Vienna *Bote* has been confiscated by the authorities on account of the advertisements contained in it of Thierry's "Wunderbalsam" and salve. Another calendar has shared the same fate on account of advertisements of a charlatan in Saxony and the salve of a firm in Budapesth. The Bohemian authorities have forbidden the "Nature-Healing Company" to establish new branch establishments.

The French Railway du Nord has constructed a two-story building in connection with its Paris depot for receiving and caring for the injured in an accident. Every detail to ensure asepsis and ample illumination day and night has been carefully studied. The three large rooms on the first floor can be thrown into one if required. There are waiting and consultation rooms, facilities for massage and radioscopy and the numerous attendants are drilled regularly in the entire processes of preparing for and applying first aid after notification that an accident has occurred. The Lariboisiere Hospital is close at hand and very severely injured persons will be taken directly there, but those requiring merely temporary care will be treated at the railroad emergency station.

Correspondence.

Degeneracy in the Army.

Chicago, Oct. 4, 1900.

To the Editor:—*The American Journal of Insanity* for July contains an article by Dr. Charles E. Woodruff on "Degeneracy in the Army," and remarks anent army musicians that "with the high musical sense there seems to be a liability of inferiority in some other ways, for they possess physical stigmata in far greater proportion than does the average soldier. They have to be managed by entirely different rules of discipline." What is true of army musicians is also true of musicians in state institutions for defective classes, etc. The most degenerate individuals of an institution are usually to be found among the members of the band. In many cases they are the most difficult to manage. A notable illustration is that of the band at the New York State Reformatory at Elmira. At one time more than two-thirds of the band were dressed in the uniform of the lowest grade; physical stigmata were so marked as to attract special attention.

It should also be remembered that marked imbecility may co-exist with great musical powers, as witness the case of "Blind Tom." Music, being one of the primitive arts of the race, is hence less likely to be affected by degeneracy than later-acquired arts.

Eugene S. Talbot, M.D.

A Uniform Classification for Health Statistics.

Lansing, Mich., Sept. 17, 1900.

To the Editor:—Referring to your editorial in The Journal of September 15, under the above title, I desire to say that it gives a somewhat imperfect impression of the nature and progress of the movement for the adoption of a uniform classification of causes of death, which is now an assured success. As the subject is one of very great practical importance, I trust that you will afford me the opportunity of making a more correct statement of the facts.

In the first place the classification quoted by you on page 706 in the report of the proceedings of the International Congress of Hygiene and Demography is evidently one of the most condensed forms of the Bertillon classification, and does not fully exemplify its nature as usually employed. This classification is not merely the " [illegible] but is t cation recommended for adoption to the International Statistical Institute by a committee headed by Dr. Jacques Bertillon at its session in Chicago during the World's Fair in 1893. Since that time it has been employed in Paris, Moscow, Madrid, Buenos Ayres, Montevideo, Havana, Boston, Baltimore, Buffalo, Milwaukee, Toledo, and many other cities of this country, besides in the States of Michigan, Vermont and Indiana and the Canadian Provinces of Ontario and Quebec. The classification reported by Dr. Bertillon's committee to the International Statistical Institute was in three forms, viz., an extended or full classification, a short form and an intermediate form. The long form is that usually referred to and is best adapted to the use of states and large cities. It contains about 160 titles, instead of the 38 given by your correspondent from Paris, and is abundantly full for all ordinary statistical purposes. The short forms are presented merely for the use of such cities as may find a condensed list more convenient for use.

The American Public Health Association did not adopt the system at Philadelphia in 1897, regarding it as a measure of very far-reaching importance and one requiring the fullest consideration. After the lapse of a year, however, at Ottawa, Canada, in 1898, the cordial assent of the Association was given, and as I believe, has been a factor of great importance in uniting the registrars of South America, Central America and Europe, with the exception of England only, in the adoption of a uniform classification for the world. I may also say that the International Conference of State and Provincial Boards of Health indorsed the system most fully at the meeting held at Detroit in 1898 just prior to the session of the American Public Health Association at Ottawa.

The action of the American Public Health Association in 1898 not only provided for the general adoption of the classification by the registration offices of Canada, Mexico and the United States after its revision, but also provided a plan for that revision and recommended that it be held at Paris in 1900 under the auspices of the International Congress of Hygiene and Demography. This plan was indorsed fully in its general features by the International Statistical Institute at its session at Christiania, Norway, in 1899, and its completion constitutes the first decennial revision of the International Classification, which you have just announced. It is intended that such a revision shall be made every ten years, with the full-co-operation of all of the registration offices employing the system, to the end that the classification shall be kept fully abreast of the advances of medical science. Unless this is done, it will rapidly grow obsolete, as have many of the systems now in use in this country, which are soon to be supplanted by the modern classification.

A short paper on this subject of uniform classification was read by me before the Section of Hygiene and Sanitary Science of the American Medical Association at the last meeting, at Atlantic City, N. J., and a resolution was passed in its favor by the Section. This resolution was indorsed by the Executive Committee, but failed to carry in the general session, owing, I believe, to the expressed opinion that the subject was a new one and the Association unprepared to take immediate action. As so much has been done since 1893, including the adoption of the system by nearly every registration State in the Union, I wish that this information could be brought generally to the knowledge of the members of the Association, so that they may be sufficiently informed to act at some subsequent session of the Association.

Dr. Bertillon informs me that the revised classification will be ready for publication in about a month, and I trust that the American Public Health Association, at its meeting soon to be held at Indianapolis, will make provision for at once preparing a translation and getting it into the hands of American registrars and public health officials, so that its use can be begun promptly on January 1, 1901. We shall then have a definite basis, alike in all parts of the country, on which to base our public health work, and as a result we may fairly expect a much increased use of mortality statistics in sanitary work, of which they form the indispensable foundation.

Cressy L. Wilbur, M.D.

[If the Bertillon classification is to be universally adopted it is to be hoped it will receive the modification it needs. Up to the present time we can not consider it a satisfactory one by any means; it is in some respects out of accord with modern pathologic ideas and almost ridiculous in some of its minor details, as given in the pamphlet published in this country. —Ed.]

Book Notices.

Practical Gynecology. A Comprehensive Text-Book for Students and Physicians. By E. E. Montgomery, M.D., Professor of Gynecology, Jefferson Medical College. With 527 illustrations, nearly all of which have been drawn and engraved especially for this work, for the most part from original sources. Cloth. Pp. 819. Price, $5.00. Philadelphia: P. Blakiston's Son & Co. 1900.

Fashion in medical book-making seems to be running to the composite, which may be advantageous, and the means of producing a better book than one written by an individual. It may be the old-fashioned notions of the reviewer, but he believes in the old idea of one book, one author, and he should have all the responsibility, all the criticism and all the glory that attach to it. The composite is likely to be written under a "rush" order; so much space, in so much time, for so much money. The work before us is the work of one individual, and the personality of that individual is evident through the whole book.

The author tells us in the preface that it has been under consideration for fifteen years and that much of it has been rewritten several times. This may readily be believed, for the result shows painstaking effort in every detail, in conciseness of statements, in arrangement of subjects and in the systematic order and completeness in which each is considered. The general plan is entirely different from that usually adopted. Instead of a division into chapters, the book is divided into sections, consecutively numbered, and with heavy black-faced "side-heads." While such an arrangement as the author uses has many advantages—an important one being an easy reference to any subject—still it has a drawback in the fact that the main subject is given no more distinctive heading than its subdivisions. This objection, however, may be more apparent than real when one becomes used to the style. By the way, the various lacerations of the pelvic floor, vaginal fistula, etc., are classified under the general head of "malformations," possibly correctly so, but hardly, according to the generally accepted meaning of the term. The manner in which the author considers the subjects of diagnosis and methods of examination shows that he appreciates the needs of the student, the difficulties to be encountered and the importance of a thorough understanding of gynecological examinations. The technique of the various operations, even the minor ones, is described in sufficient detail to enable the student to understand every stage of procedure. This, with the wealth of illustrations, makes the appreciation of the various stages an easy matter.

The author is neither too radical nor too conservative in his consideration of the conditions that may need radical operations. In the introduction he tells us that the true gynecologist must be "so conservative that he will sacrifice no organ whose physiologic integrity is capable of being restored; so bold and courageous that his patient shall not forfeit her opportunity for life or restored health through his failure to assume the responsibility of any operative procedure necessary to secure the object." This is the basal idea that permeates the book; the ultra-radical operator will find no endorsement, and the "tinkering" gynecologist—he who treats all diseases of women by means of a pledget of cotton and a speculum—no encouragement in its pages.

The book is one that can be recommended to the student, to the general practitioner—who must sometimes be a gynecologist to a certain extent whether he will or not—and to the specialist, as an ideal and in every way complete work on the gynecology of to-day—a practical work for practical workers.

A Manual of Surgical Treatment. By W. Watson Cheyne, M.D., F.R.C.S., F.R.S., professor of surgery in King's College, London, and F. F. Burghard, M.D., M.S., F.R.C.S., teacher of practical surgery in King's College, London. Volume III. The Treatment of the Surgical Affections of the Bones; Amputations. Cloth. Pp. 305. Price, $3.50. Philadelphia and New York: Lea Bros. & Co. 1900.

The present volume treats of the surgical affections of the bones and of amputations. As the work is a "Manual of Treatment," the pathology, symptoms, diagnosis, etc., of the various conditions are but briefly mentioned, often to the disadvantage of the work, because the selection of some particular method of treatment so often depends on a recognition of the exact conditions present that it is advisable to discuss the points together.

In the treatment of fractures many little points are detailed which are of great value to the surgeon and which are seldom found described in text-books on surgery. The advice to immediately wire all fragments will be concurred in by most surgeons, but they would prefer to immobilize a knee-joint by splint or cast after wiring a fractured patella before allowing it to remain without fixation, as recommended.

The statement is made that the difficulty in the treatment of the so-called T-shaped fractures of the lower end of the humerus "is so great that it is almost hopeless to attempt to obtain a useful movable joint by treating the fracture merely by splinting and massage; the only probability of getting a really good result is by operative interference." This is entirely too radical, and many excellent results have been obtained in these cases by proper fixation, and better results, too, than would probably follow indiscriminate attempts to fix by pegs or wire the small cartilaginous epiphyses, as it is in young children that the majority of these fractures occur. Unquestionably there are cases attended by displacement or rotation of the fragments that would be best treated by operation, but they are not in the majority.

On the whole, the chapters on fractures are well written and the practitioner will find much information of great value in the handling of these troublesome cases. Under "Fatty Embolism," a distinct contradiction is found. Of the symptoms it is stated: "They generally come on within a few hours." A few lines farther down we find: "As a rule they (the symptoms) do not come on for some hours after the injury."

The chapters on infections of the bones, tumors, etc., are only fair. The various amputations are well described and illustrated, although several methods are omitted, as for instance, Wyeth's excellent method of controlling the hemorrhage in amputation at the hip-joint.

The volume is of convenient size and the publisher's work well done.

Surgical Anatomy. A Treatise on Human Anatomy in its Application to the Practice of Medicine and Surgery. By John B. Deaver, M.D., Surgeon-in-Chief to the German Hospital, Philadelphia. In Three Volumes, Illustrated by About 400 Plates, nearly all Drawn for this Work from Original Dissections. Vol. II. Royal Octavo, One-half Morocco, pp. 709. Price $8. Philadelphia: P. Blakiston's Son & Co. 1900. Comprises the Neck, Mouth, Pharynx, Larynx, Nose, Orbit, Eyeball, Organ of Hearing, Brain, Male Perineum, Female Perineum.

This second volume of Deaver's Surgical Anatomy is in every way up to the high standard of the first, and will make as good an impression as did its predecessor. All that we said last year of the first we would repeat of the second volume. This one covers the most important structures of the body, and the parts that baffle the student in his endeavors to master their intricacies—the head and neck. The author's descriptive style is concise, clear and easily understood, and this, with the excellent illustrations, makes his book one that will be popular, not only with the student, but with the surgeon and general practitioner. Nothing can take the place of the cadaver as a method of mastering anatomy, but Deaver's work will make an excellent substitute. The illustrations are all full page, are works of art, beautiful; but above all, are of great practical value, as they reflect perfectly the artist's true delineation of Nature. There has been an evident disregard of expense in supplying them, both as to quality and quantity. It would not be fair to the author, or true, to say that the illustrations are the more important part of the work, but they are certainly very attractive and place it in the front rank as an illustrated medical work.

Occasionally matter has crept into the text that belongs to a work on surgery and not to one on surgical anatomy. The impression the reader will get is that once in a while the author forgot himself and thought he was writing a text-book on surgery, else why so much on technique and so little on structures in several instances? Quite a number of the full-page illustrations occur twice, among them being clxi, clxii, clxiv, clxv, clxvi, clxxviii. We presume these are duplicated for a purpose, although we fail to understand what that might be.

Clinical Examination of the Urine and Urinary Diagnosis. A Clinical Guide for the Use of Practitioners and Students of Medicine and Surgery. By J. Bergen Ogden, M.D. Illustrated. Cloth. Pp. 416. Price, $3.00. Philadelphia: W. B. Saunders & Co. 1900.

This is a new work on urinary analysis, and a thorough one in its special branch of chemical examination. The author states in his preface that he has aimed to present in as concise a manual as possible the chemistry of the urine and its relation to physiologic processes, the most improved working methods, both qualitative and quantitative, the diagnosis of diseases and disorders of the kidneys and urinary passages. The book is divided into two parts. In the first part the chemical and microscopical methods are described in detail, and numerous illustrations, many original, have been introduced; it will form a convenient and satisfactory manual of its subject. The second part treats particularly of the diagnosis, including our present knowledge of the character of the urine in, and the differential diagnosis of, diseases of the kidneys and the urinary passages, with a brief statement of the different signs in the different forms of disease. A chapter is also given to the characteristics of the urine in diseases outside of the urinary tract, such as fevers, pneumonia; infectious diseases, like cholera, scarlet fever, diphtheria, tuberculosis; disorders of the intestines and of the nervous system, as well as general conditions like anemia, scurvy and certain forms of poisoning. The appendices illustrate methods of recording urinary examinations and give inventories of the reagents and the apparatus required. The work is an eminently satisfactory one and one likely to fulfill its object.

Anatomy of the Brain. A Text-Book for Medical Students. By Richard H. Whitehead, M.D. Professor of Anatomy in the University of North Carolina. Illustrated with Forty-one Engravings. 6¼ by 9½ Inches. Pp. 96. Extra Vellum Cloth, $1 net. Philadelphia: The F. A. Davis Co.

This brief and convenient manual of the general anatomy of the brain, with its numerous schematic drawings, which are a great advantage to the student, seems, as far as it goes, to represent our present knowledge of the subject. The author, as he says, thought best to omit minor details, and exclude as far as possible subjects which are still matters of controversy. The student, therefore, will find in his further studies many additional facts not here mentioned. The original names for the parts are given, but the terms adopted and recommended by the German Anatomical Society are inserted parenthetically. It would not have been inappropriate and would have been in the line of progress if the author had also parenthetically inserted the nomenclature of Wilder, some of which at least is likely to come into general use. The book is one that will undoubtedly be serviceable and can be recommended to the student.

Lectures on the Principles of Surgery, Delivered at the University of Michigan. By Charles B. Nancrede, A.M., M.D., LL.D. With an Appendix Containing a Résumé of the Principal Views held concerning Inflammation, by Wm. A. Spitzley, A.B., M.D. Illustrated. 8vo. Cloth. Pp. 398. Price, $2.50 net. Philadelphia: W. B. Saunders. 1899. W. T. Keener, Chicago Agent.

This volume is written in lecture style and is evidently intended for students. The changes which take place in normal wound-repair are first described, and the differences between repair and inflammation clearly defined. The growth of microbes in the wound is made the distinguishing point of inflammation, and the various complications which may arise as a result of the different kinds of infections are briefly discussed. Hemorrhage, shock, methods of sterilization and the administration of anesthetics are also considered, and the volume closes with a brief historical appendix on inflammation, by W. A. Spitzley, A. B., M.D.

The work is clearly written, and expresses the author's own views, without entering deeply into the subjects. It is well adapted to give to the student a general outline of the subject and work before him.

Psychopathia Sexualis. With Especial Reference to Antipathic Sexual Instinct. A Medico-Forensic Study. By Dr. R. v. Krafft-Ebing, o. ö. Prof. Für Psychiatrie und Nervenkrankheiten an der K.K. Universität, Wein. The Only Authorized English Translation of the Tenth German Edition. Cloth. Pp. 585. Price, $5.00. Chicago: W. T. Keener & Co. 1900.

It is not often that a foreign work passes through two separate translations into the English language, as is the case with the present one. The reason why this is so is rather obvious, though it can not be especially justified. The book is one of a small class that is much more widely read than it should be, by non-medical readers. Its proper place is on the reserve shelves, sometimes called "hell," of a well-conducted library. The author has enlarged it considerably, and the present translation appears to be a very satisfactory one. We can not recommend the book generally, but it will, of course, recommend itself to those who want to read it. This undoubtedly is the most complete, or at least the largest work, on its subject in our or any other language. The present volume has one advantage, or it may be such, that the Latin language is more frequently made use of than in the former editions. The author's wishes for its good reception will undoubtedly be gratified. What we object to in the work is the morbid popularity it has gained.

Idroterapia. Del Prof. Gaetano Gibelli, Proprietario del gabinetto elettro-termo-baro-idroterapico, Milano, Via Manzoni, 50 Con. 30 incisioni. Cloth. Pp. 237. Milano: Ulrico Hoepli. 1900.

The subject of hydrotherapy is given in a brief compass and apparently covering the subject. The chief thing about the work which makes an unfavorable impression occurs in the rather florid mention of certain empirics and their methods, especially Father Kneipp, who is not considered worthy of the same notice by other works. The book, however, to those who read Italian, will probably be a convenient, though limited, handy manual on the subject.

L'Assistenz dei Pazzi nel Manicomio e nella Famiglia. Istruzioni elementari per infermeiri ed infermiere. Dott. A. Pieraccini, Vice Direttore del Manicomio Provinciale di Macerata. Con Prefazione del Prof. A. Morselli, Direttore della Clinica Psichiatrica di Genova. Cloth, Pp. 64. Milano: Ulrico Hoepli. 1901.

This volume, one of the numerous Hoepli manuals, is a hand-book for instruction to mental nurses and asylum attendants, covering apparently the whole ground of their duties. It has the advantage of considering certain subjects which are not ordinarily discussed in nursing-manuals; thus the methods of transporting patients to asylums, distinctions between real and apparent death, the ethics of the business of attendants on the insane, etc., are fully discussed. It is a very excellent little work in its way.

The Microtomist's Vade-Mecum. A Handbook of the Methods of Microscopic Anatomy. By Arthur Bolles Lee. Fifth Edition. Cloth. Pp. 532. Price, $4.00. Philadelphia: P. Blakiston's Son & Co. 1900.

This is the fifth edition of a work which has been before the medical public for a number of years; revised up to date. A number of references and methods have been eliminated as superfluous, and repetition and unnecessary amplifications have been avoided so as to keep the book within the old limits of size. Considerable new matter in regard to methods has been added. The book will maintain its former popularity not only with the medical profession, but with biologic workers as well.

Clinical Examination of Urine with an Atlas of Urinary Deposits. Including Forty-one Original Plates. Mostly Colored. By Lindley Scott, M.A., M.D. Cloth. Price, $5. Philadelphia: P. Blakiston's Son & Co. 1900.

In addition to the two books noticed above, we have this one which has the special advantages of presenting in large plates, colored and otherwise, the microscopic features observed in urine examinations. The principal methods and tests are also given, and while not extensive in its scope it will undoubtedly meet with favor among those who wish a convenient, handy, and brief manual of its special subject. It is handsomely gotten up, and the illustrations are scientifically correct, as well as otherwise excellent.

Practical Uranalysis and Urinary Diagnosis. A Manual for the Use of Physicians, Surgeons, and Students. By Charles W. Purdy, LL.D., M.D., Fellow of the Royal College of Physicians and Surgeons, Kingston. Fifth Revised and Enlarged Edition. With Numerous Illustrations. Including Photo-engravings and Colored Plates. Cloth. Pp. 392. Price, $3.00 net. Philadelphia: F. A. Davis Co. 1900.

This book is evidently being well received, as it is the fifth edition within six years, thus showing that it has met with the favor of the profession. The author has extended it considerably, bringing in accounts of new methods, adding new tables and giving it a general revision.

Medical Diagnosis With Special Reference to Practical Medicine, a Guide to the Knowledge and Discrimination of Diseases. By J. M. Da Costa, M.D., LL.D., physician to the Pennsylvania Hospital. Illustrated. Ninth edition, revised. Price, $5.00. Philadelphia and London: J. B. Lippincott Company. 1900.

This work has been thoroughly revised, partially rewritten, and brought up to date in all its departments. Da Costa's has for years been recognized as a standard text-book on diagnosis, and this revision has made it possible for it still to maintain the enviable position it has held so long.

Deaths and Obituaries.

Samuel Smith Purple, M.D., died at his home in New York, from heart disease, September 29, aged 78. He was graduated in 1844 from the University of the City of New York. His earliest attention was given to medical editorship, dispensary work and society organization. A special fondness for medical history and biography with a genealogical bias was subsequently developed. He was editor-in-chief of the *New York Journal of Medicine* from 1848 till 1857; president of the New York Academy of Medicine in 1875, and re-elected in 1877; and president of the Alumni Association of the Medical Department of the University of the City of New York, from 1867 till 1871. He made the first donation of 4000 volumes to the library of the Academy of Medicine. At the time of his death he owned one of the largest private libraries in New York, containing many exceedingly rare volumes.

Theodore N. Wise, M.D., died September 26, at his home in Covington, Ky., from Bright's disease, after a long illness. He was born at Alexandria, Va., June 29, 1817, was graduated from the Medical College of Ohio in 1837, and immediately began the practice of medicine in Covington.

Joseph F. Mulcahy, M.D., Lowell, Mass., died after a long illness, September 24, aged 36. He was a graduate of the medical department of the University of New York, in 1891, and was dispensary physician and a member of the staff of St. John's Hospital for several years.

Joseph Trepp, M.D., one of the oldest practitioners in Adrian, Mich., a graduate of the medical department of Western Reserve University, Cleveland, O., in 1854, died September 25, as a result of accidental injuries recently received, at the age of 73.

CLARE W. VIRTUE, M.D., who was graduated from the College of Physicians and Surgeons, Chicago, in 1897, and settled in Akron, O., died September 28, at the age of 30, after a five weeks' illness of diphtheria contracted from a patient.

ROBERT B. SIBLEY, JR., M.D., a graduate of the University of Louisville medical department in 1898, who was obliged to go to Colorado by reason of lung disease, locating in Aspen, died recently from consumption.

RICHARD H. WHITE, M.D., a graduate of Trinity Medical College, Toronto, in 1891, and physician of the lung department of the New York Nose and Throat Hospital, died from phthisis, at Liberty, N. Y., September 26, aged 32.

JAMES M. MONTMOLLIN, M.D., formerly surgeon of the Chesapeake and Ohio system, died after a long illness, at his home, Ashland, Ky., September 24. He was graduated in 1862 from Jefferson Medical College, Philadelphia.

JAMES A. INGRAM, M.D., a graduate of the medical department of Western Reserve University, Cleveland, O., in 1880, and a practitioner in Cleveland since that time, died September 24, from Bright's disease, aged 41.

GEORGE F. KOEPSTEIN, M.D., who studied at the University of Breslau, received his degree in 1886, and had practiced for several years at Guttenberg, Ia., died at Finley Hospital, Dubuque, September 28.

S. POTTS EAGLETON, M.D., formerly of Philadelphia, a graduate of the University of Pennsylvania in 1890, and assistant-surgeon to Will's Eye Hospital, died at his home in Ocala, Fla., aged 33.

JAMES A. MOORS, M.D., who was graduated from the College of Physicians and Surgeons, New York, died, September 26, after fourteen years of invalidism at West Winfield, N. Y., aged 43.

SAMUEL S. DOWNS, M.D., Waterville, Ohio., a graduate of Miami Medical College, Cincinnati, in 1873, died after a long illness from tuberculosis, in Ellsworth, Kan., September [illegible].

H. FINLEY BURT, M.D., who was graduated from the medical department of the University of the South, Sewanee, Tenn., in 1892, died at Sweetwater, Tex., September 26, aged 34.

EDWARD N. WEBSTER, M.D., St. Louis, Mo., who was graduated from Barnes Medical College in 1893, died September [illegible], four days after a surgical operation, aged 32.

LINNAEUS G. WILLIAMS, M.D., Fostoria, O., who was graduated from the University of Wooster, medical department, Cleveland, in 1876, died suddenly, September 24.

HENRY JERVEY, M.D., Sublette, Va., who was graduated from the Medical College of the State of South Carolina, Charleston, in 1861, died after an illness of six months.

THOMAS J. CONEY, M.D., a graduate of Kansas City Medical College in 1871, formerly surgeon for the Santa Fe Railroad, died September 15 at Seguro, Colo., aged [illegible].

JAMES W. BRYANT, M.D., Richmond, Va., who was graduated in 1844 from the department of medicine of the University of Pennsylvania, died September [illegible], aged [illegible].

WILLIAM H. MUNN, M.D., a graduate of New York University, medical department, in [illegible], died at Bellevue Hospital, September 24, from cerebral congestion.

CURTIS F. HAWLEY, M.D., died at his home in [illegible], September 24, aged 74. He was graduated from [illegible] Medical College, Vermont, in [illegible].

DAVID F. [illegible], M.D., Kansas City, Mo., a graduate of the Medical College of Indiana, Indianapolis, in [illegible], died recently at Cape Nome, Alaska.

EDWARD PATTERSON, M.D., [illegible], died September 24, aged [illegible]. He was a graduate of Jefferson Medical College, Philadelphia.

SAMUEL S. DOWNS, M.D., Waterville, O., who was graduated in 1873 from Miami Medical College, Cincinnati, died recently in Kansas.

JAMES M. [illegible], M.D., one of the oldest and most prominent physicians of [illegible], died September [illegible], aged 73.

Miscellany.

Obstruction of Common Bile-Duct by an Ascaris.—P. Ferrari relates in the *Brazil Medico* a case where the diagnosis wavered between obstruction of the common bile-duct and suppurative hepatitis; the patient was previously a healthy woman. Exploratory puncture was negative, but at the autopsy the duct was found plugged with a macerated ascaris, 20 cm. long.

Last Sign of Life.—W. D. Waller presented to the Paris Académie des Sciences, as related in the *Bulletin Médical*, Sept. 29, the galvanometric test based on the fact that living matter responds to electric stimulation by a current in the same direction. The same matter after it has been deprived of life, fails to respond at all to electric stimulation or else starts a contrary current of polarization.

Alvarenga Prize.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, amounting to about $180, will be made on July 14, 1901. Essays intended for competition may be on any subject in medicine, but can not have been published, and must be received by the secretary of the college on or before May 1, 1901. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author.

Autofixation of Movable Kidney.—Biondi has been very successful in suspending a movable kidney in thirteen cases without sutures or threads, and recommended his process at the International Congress. He exposes the organ and removes the adipose and fibrous capsules, then tampons it in place with a long strip of gauze wound in and out to fill the entire space in front of the lower pole and below the kidney. The decapsulated organ becomes firmly fastened by granulation tissue in the course of a week, when the gauze is removed. Tests on dogs showed that a new fibrous capsule forms which [illegible]. The kidneys thus treated in his cases retained their weight and showed no appreciable alteration.

Rupture of Vulvar Varices During Delivery.—In [illegible] cases that have been published, [illegible] of the patients died, all but three in less than thirty minutes. [illegible]

[illegible]—[illegible]

bellious neuralgia, Pitres injects 1 to 2 cg. of cocain on the route of the affected nerve. If the pain persists undiminished by the cocain the neuralgia is probably of central origin and intervention would be fruitless. If the pain is abolished by the cocain the lesion is probably peripheral and an operation has every chance of curing by removal of the nerve causing the neuralgia. It should always be divided above the part involved and the exact point can be established with the cocain. The lancinating pains in ataxia can be relieved for three hours by intraspinal injection of about 15 mg. of cocain, which is also usually effective in relieving the pain of sacrodynia, coccydynia, talalgia, etc., in the absence of organic lesions. Some of these neuralgias may be permanently cured by this procedure.—*Int. Med. Congress.*

Treatment of Mucomembranous Colitis.—At the Thirteenth International Medical Congress held recently at Paris, Mathieu recommended among other things, correction of the constipation that is usually present. For this purpose measures should be employed that do not increase the secretory irritation, the pains or the tendency to spasm. Castor-oil, large enemata and belladonna are especially useful. The first should be given in small doses in the morning before breakfast. Its employment should alternate with that of the large enemata, which should be given at low pressure, slowly and at a temperature of about 104 F. in amounts of from 3 to 5 pints. These enemata soothe the painful and spasmodic irritation of the intestines, induce evacuation of the material accumulated within it, and act as a mechanical antiseptic. They may consist of boiled water with a weak solution of sodium biborate or sodium salicylate, or a dilute solution of neutral ammonium ichthyolate. Care should be taken to avoid all agents likely to cause irritation of the bowel, such as drastic purgatives, astringent injections and massage in cases attended with marked hyperesthesia of the intestine or painful spasm of the colon. Food rich in vegetable detritus—green vegetables, stewed fruits, bread made from whole wheat, etc.—has sometimes been recommended, but in many cases this will not be tolerated, and it becomes necessary to prescribe a regimen that favors constipation while it lessens the irritation of the digestive mucous membrane. Enemata of oil are often useful, especially when combined with large enemata at low pressure. Belladonna is frequently successful, soothing pain and antagonizing the tendency to spasm. More rarely recourse may be had to opium and its derivatives. Hot local applications and hot baths have a useful sedative effect. Prolonged baths and large hot enemata form the basis of treatment at certain health resorts. It is often of advantage to administer sedatives and employ hydrotherapy for the effect on the general neurosis. Often the patients are debilitated and emaciated, and it is necessary to improve the nutrition and at the same time to prescribe a regimen more appropriate to the state of the digestive canal. Dysenteriform attacks should be treated with enemata of a weak solution of silver nitrate, and hemorrhage by preparations of hamamelis and large enemata at a temperature of 113 F.

MARINE-HOSPITAL NOTES.

The Reedy Island Quarantine Station was seriously damaged on September 22 by the steamship *Falladon Hall*, which ran into the signal tower of the station. Damages estimated at $15,000.

The marine hospital established this spring at Dutch Harbor, Alaska, for the care of sick and disabled seamen, will be closed for the winter, as all communication with that point is discontinued on account of ice. It will be opened again in the spring as soon as commercial communication can be had.

PLAGUE SITUATION IN GLASGOW.

A report from P. A. Surgeon Thomas, Sept. 18, 1900, records seven new cases, with two deaths, leaving twenty-one cases then under treatment. The new cases originated in old foci. One female employee at the hospital had a mild attack after being inoculated with Yersin's serum. Haffkine's prophylactic has not been used because of the reaction which follows. Under the use of Yersin's serum there has been great uniformity of symptoms, namely, slight soreness for a day or two and, at the end of eight days, usually some urticaria and, less commonly, joint pain. A local dermatitis has probably been due to the disinfectant used on the arm.

NO YELLOW FEVER THIS YEAR.

There has been no yellow fever in the United States this season, which has now so far advanced as to give assurance against an epidemic. It is a cause for special congratulation, particularly as it has prevailed in greater or less degree each of the last three preceding summers and falls. The chief points of danger to the United States have been Havana and Vera Cruz. The smaller cities on the Pacific Coast of Central America are many of them in wretched sanitary condition, and some of them are foci of yellow fever; and as these Pacific Coast ports are annually coming into closer commercial relations with the Atlantic ports, their importance from an epidemiological standpoint becomes magnified. It is gratifying to know that Guayaquil, in Equador, which has heretofore been notably afflicted with a pernicious fever, is being sewered and drained under an American civil engineer. There have been a few cases of yellow fever in one or two of the Central American fruit ports, but no epidemic. There have been a few cases of yellow fever at Tampico, Mexico, and also Merida, which is in close communication with its seaport, Progreso. While the number of infected places has been in a measure limited, in the beginning, of course, it was impossible to say how many there would be, and protective measures were taken early by the Marine-Hospital Service with regard to all yellow fever suspected seaports. Its operations may be considered to have begun in the winter, when Acting Assistant-Surgeon Hodgson was sent on a tour embracing all the Pacific and Atlantic Coast towns of Central America. His reports, showing the conditions, have been printed in the public health reports. At the beginning of the quarantine season seven acting assistant-surgeons were appointed in as many cities on the Atlantic Coast of Central America at what was termed the fruit ports, to put in operation measures which would enable fruit vessels to be admitted without detention at quarantine at this end (which detention is ruinous to their cargoes), even should a case or two of yellow fever be discovered at the port subsequent to their departure. These fruit port regulations have been rigidly enforced. At Vera Cruz an acting assistant-surgeon of the Marine-Hospital Service was detailed in the office of the United States consul and directed to sign bills of health with the consul. He also kept track of people who left Vera Cruz for the United States overland, and on the Texas border of Mexico, at three points, namely, Eagle Pass, Laredo and El Paso, officers of the Marine-Hospital Service have been and are still stationed to detect any passengers arriving from an infected area and to hold any such a sufficient length of time to cover the incubation period of the disease. Each station is provided with a detention camp and the records of the officers show that a number of persons were thus detained and held. In Cuba there has been no serious outbreak of yellow fever excepting in Havana. Here the Marine-Hospital Service has had a large force of officers and employees, with practically three establishments: one the quarantine station proper at Mariel, some twenty odd miles from Havana, for the reception of infected vessels; another, the disinfecting steamer *Sanator*, for the disinfection of ships leaving for the United States, and the third, a shore plant for the disinfection of baggage of passengers leaving, supplementary to the work of the *Sanator.* All are under the charge of an officer of the Marine-Hospital Service, who, by executive order, has been designated as chief quarantine officer of the Island of Cuba, and is detailed on the staff of General Wood, thus insuring harmony of action between the island military authority and the Marine-Hospital Service. The regulations have required all baggage from Cuba labeled either "inspected" or "disinfected," and since the outbreak of yellow fever in Havana all baggage from that port has been, and is still being, disinfected. The *Sanator*, a description of which was published in The Journal, under date of May 26, 1900, has proved a very efficient vessel. It is the finest vessel of its kind afloat.

Therapeutics.

Castor-Oil Made Palatable.

℞.	Saccharin	gr. xii		75
	Olei gaultheriæ	m. xx	1	33
	Alcoholis	ʒiv	16	
	Olei ricini	Oi	512	

M. Sig. One tablespoonful at bedtime.

The addition of saccharin, aromatic oil and alcohol is of use in rendering cod-liver oil palatable —*Canada Lancet.*

Creolin in Intestinal Fermentation.

℞.	Creolin	ʒiss	6	
	Alcoholis diluti	m. xv	1	
	Ext. glycyrrhizæ			
	Pulv. glycyrrhizæ, āā	ʒiss	6	
	Gum *tragacanthæ*	gr. xv	1	

M. Ft. pilulæ No. 100. Sig. One pill three times a day.
—*Ther. Gazette.*

Creolin is a dark alkaline fluid derived from coal-tar. It is an antiseptic devoid of irritating properties and is beneficial in treatment of many skin affections. David Walsh, in the *Therapist*, recommends it in the treatment of eczema:

℞.	Creolin	ʒi	4	
	Aquæ destil.	Oi	512	

M. Sig. Sponge the parts well two or three times a day, then apply the following dusting powder:

℞.	Europhen	gr. xxx	2	
	Zinci oxidi	ʒii	8	
	Amyli	℥i	32	

Chronic Eczema.

In chronic eczema Walsh uses the following ointment:

℞.	Creolin	ʒss	2	
	Hydrarg. ammoniati	gr. x		66
	Vaselini	℥i	32	

M. Sig. Rub well into the dried patches night and morning.

Eczema of the Upper Lip.

℞.	Thiol	gr. vii		5
	Acidi borici	gr. lxxv	5	
	Menthol	gr. ½		03
	Vaselini	℥i	32	

M. Sig. Apply morning and night.

Or,

℞.	Hydrargyri oxidi flavi	gr. x		66
	Vaselini	ʒvi	24	

M. Sig. At night wash the inflamed parts with a hot boric-acid solution, then touch them with spirits of camphor and apply the ointment.

During the day apply the following:

R.	Resorcin	gr. iii		2
	Acidi salicylici	gr. iv		25
	Zinci oxidi	gr. xlv	3	
	Lanolini	ʒiss	6	
	Vaselini	ʒiii	12	

M. Sig. Apply to the lip in the morning after cleansing with hot water. —Brocq.

Thiol is a product of hydrocarbons obtained in a similar manner to ichthyol. It is a brownish-black powder, soluble in water and alcohol. and is used extensively in the form of an ointment in the treatment of various skin diseases, and can be substituted for ichthyol.

For Recent Rheumatic Neuralgias..

℞.	Phenacetini	ʒi	4	
	Salol	gr. xl	2	66
	Caffeinæ citratæ	gr. v		33

M. Ft. cachets No. x. Sig. One every four or five hours.
—Domanski: *Zeo Manual of Ther.*

Typhoid Fever.

℞.	Acidi carbolici	mx		66
	Syr. aurantii	℥ss	16	
	Aquæ destil., q. s. ad	℥ii	64	

M. Sig. One teaspoonful every two hours. —M. A. Davis.

Intestinal Antiseptic.

℞.	Ichthoform	ʒiiss	10	

Ft. capsulæ No. xxx. Sig. One or two capsules three times a day.

Wilcox, in *Jour. Med. Science*, notes the study of the above preparation by Rabon and Galli-Valerio. It is a combination of ichthyol and formaldehyde. Experiments have shown it to hinder the development of bacterium coli, bacillus typhosus, bacillus icteroides, bacillus pyocyaneus and staphylococcus pyogenes aureus. It may be administered in doses of 30 to 45 grains per day.

Surgical Shock.

℞.	Digitalin	gr. 1/3		02
	Strychninæ arsenatis	gr. i		06
	Nuclein	gr. lx	4	
	Atropinæ sulphatis	gr. 1/10		006
	Syrupi tolutani	℥iv	128	

M. Sig. One teaspoonful repeated in an hour or two as necessary.

Martin, in the *Medicus*, states that he has obtained excellent results from the use of the above prescription. In connection with this treatment he uses hot applications to the feet and around the body and administers hot coffee freely.

Tests prove that any other portion of the gastrointestinal tract will absorb strychnin more rapidly than the stomach.
—*Med. Sum.*

Treatment of Hiccough.

℞.	Sodii bromidi			
	Potassii bromidi, āā	ʒi	4	
	Ammonii bromidi	ʒss	2	
	Syrupi simplicis, q. s. ad	℥iv	128	

M. Sig. One tablespoonful every hour until relieved.

H. Klein, of Chicago, states that he was successful in checking the hiccough in a patient, which had continued for four days, by the administration of two doses of the above preparation.

Traction of the Tongue in Hiccough.

J. Noir, in *British Med. Journal,* states that he has had success in treatment of hiccough by means of Laborde's method of applying vigorous traction to the tongue. In one case of six hours' duration, traction on the tongue for one and a half minutes arrested the trouble. He also reports another case of six days' duration in which a cure was effected in two minutes by the same method. —*Canadian Pract. and Review.*

Treatment of Obesity.

The *Canada Lancet* gives an outline of von Hosslin's treatment of obesity:

1. Nourish the patient with a purely albumin diet.
2. Increase metabolism by means of hydrotherapy, in the form of cold applications and sweat baths.
3. Administer thyroid extract.
4. Increase oxidation by means of bodily exercise.

Von Hosslin insists on carrying out the above lines of treatment in detail and reports that the omission of any part of it is likely to cause increase in the patient's weight.—*Med. Age.*

Milk Leg—Phlegmasia Dolens.

℞.	Ext. hamamelidis fluidi	℥i	32	
	Elixiris simplicis			
	Syrupi simplicis, āā	℥ss	16	

M. Sig. One to two teaspoonfuls three or four times a day.
—Preston: *Dominion Med. Monthly.*

Or,

℞.	Ext. belladonnæ fluidi	ʒi	4	
	Tinct. opii	℥i	32	
	Tinct. iodi	ʒi	4	
	Olei olivæ	℥viii	256	

M. Sig. Apply to the leg as warmly as can be borne and bandage. —*Smith.*

Ovarian Neuralgia.

℞.	Ext. belladonnæ	gr. iv		25
	Ext. stramonii	gr. v		30
	Lactophenin	ʒiss	6	

M. Ft. pilulæ No. xx. Sig. One pill three times a day.
—C. S. Martin.

Acute Bronchitis.

℞.	Vini ipecacuanhæ		
	Vini antimonii, āā	ʒii	8
	Glycerini	ʒiv	16
	Sol. ammoniæ acetatis	℥i	32
	Aquæ, q. s. ad	℥iii	96

M. Sig. One teaspoonful every three or four hours.

—*Med. Record.*

Rheumatic Joints.

℞.	Acidi salicylici	℥ss	16
	Olei terebinthinæ	℥ss	16
	Lanolini	℥i	32
	Adipis, q. s. ad	℥iii	96

M. Spread on lint and apply, cover with oil silk and soft bandage. —*Goillard's Med. Journal.*

Arthralgia (Rheumatic Pains in Joints).

℞.	Etheris		
	Alcoholis		
	Methyl salicylatis, āā	℥i	32
	Linimenti saponis, q. s. ad	Oi	512

M. Sig. As a liniment to be rubbed thoroughly into the joints.

Methyl salicylate is the active principle of wintergreen, of which oil of gaultheria contains 90 per cent.

—Encyclopedia of Med. and Surgery.

Gonorrheal Epididymitis.

℞.	Sodii salicylatis	ʒii	8
	Codeinæ sulphatis	gr. x	66
	Aquæ menthæ piperitæ	℥ii	64

M. Sig. One teaspoonful every three hours.

—*Interstate Med. Journal.*

Mastitis.

With Threatened Asbcess of Mammary Gland.

The *Annals of Gynecology* recommends the following:

℞.	Tinct. phytolaccæ dec	℥ss	16
	Aquæ	Oi	512

M. Sig. To be used as a dressing.

The water should be warmed before applied.

—*Med. Summary.*

To Prevent Abortion.

℞.	Ext. hydrastis fluidi		
	Ext. hamamelidis flu.		
	Ext. virburni prunifolii flu, āā	℥i	32
	Tinct. opii	ʒiss	6

M. Sig. One and a half teaspoonful in half glass of water three times a day. Bossi: *Med. Sum.*

Vermifuge Enema—Threadworms.

℞.	Ext. quassiæ fluidi	℥iss	48
	Aquæ	℥iiss	80

M. Sig. One tablespoonful with an equal quantity of warm water as an enema, to be retained as long as possible.

—Gould and Pyle.

Emetic for Children.

℞.	Pulv. ipecacuanhæ	gr. xx	1 33
	Aquæ (boiling)	ʒv	20

Pour on and strain and add:

	Honey of squills	℥ss	16

Sig. Give one teaspoonful every ten minutes until emesis is produced. —Gould and Pyle.

Pulmonary Emphysema.

℞.	Potassii iodidi	ʒi	4
	Aquæ, q. s. ad	℥ii	64

M. Sig. One teaspoonful after each meal in water, avoiding starches.

Give the above for twenty days in each month and during the remaining ten days the following:

℞.	Sodii arsenatis	ʒss	2
	Aquæ, q. s. ad	℥ii	64

M. Sig. One teaspoonful after each meal.

And every eighth day give gr. iss of aloes with the meal; light diet, plenty of milk, no alcohol nor tobacco.

—*Jour. de Méd de Paris.*

Arthritis.

℞.	Extracti hyoscyami	gr. xv	1
	Iodoformi	gr. xxx	2
	Sodii salicylatis	ʒiss	6
	Petrolati	ʒv	20

M. Sig. As an external application. —*Therapist.*

Erysipelas.

℞.	Iodoformi	℥i	32
	Creolin	℥ss	16
	Lanolini		
	Vaselini, āā	℥i	32

M. Ft. unguentum. Sig. Apply locally.

Mracek: *Texas Med. Jour.*

Palatable Effervescent Quinin.

℞.	Quininæ sulphatis	ʒi	4
	Acidi citrici	ʒiiss	10
	Syrupi aurantii corticis	m. xv	1
	Syrupi simplicis	m. xv	1
	Aquæ destil, q. s. ad	ʒv	20

M. Sig. Add ten or twenty drops to two ounces of water containing five or six grains of sodium bicarbonate.

Ten drops of the mixture contains about one grain of quinin.

—*Therapist.*

Medicolegal.

Temporary Mental Aberration No Defense.—In the case of Castlin vs. State, in which it affirms a conviction of murder, the Court of Criminal Appeals of Texas says that it knows of no such defense as temporary mental aberration, as produced by adequate causes and arising from surrounding circumstances. It says that if the party accused of the crime was insane, and did not know the nature and quality of his act, then he was not amenable to punishment. If he was not insane, and did know the nature and quality of the act, and did know right from wrong, at the time of the commission of the offense, then he would be amenable to the law.

Contradiction by Certificate.—In Smith vs. Standard Life and Accident Insurance Company of Detroit, an action brought to recover on an accident insurance policy, the Supreme Court of Minnesota holds that, in view of the testimony of an attending physician to the effect that the death of the insured was the result of an injury, it was error to exclude from the consideration of the jury a certificate of the cause of such death, signed by that physician, which, to some extent, contradicted his oral testimony, a proper foundation for the introduction of the certificate having been laid.

Notification of Imminence of Death Not Needed.—To render admissible in evidence an ante-mortem statement as to the cause of death, made by a person soon after receiving an injury from which he died, the Supreme Court of Idaho holds, in State vs. Yee Wee, that it is not necessary that it be first shown that the attending physician informed the maker of the statement before he made it that he was going to die. To make such a statement admissible it must be shown that it was made under the belief that death was impending, the imminence of death being apparent at the time. But it makes no difference, the court says, what influence induces the person, whose death is apparently imminent, to believe that he is about to die—whether from his own condition and feelings, or the advice of a physician. His statement as to the cause which brings about his death, made under such circumstances, is admissible in evidence.

Plea for a Medical Defense Union in the United States—The medical profession has many difficulties with which to contend, and one that undoubtedly weighs heavily upon its members is the disadvantages under which they labor in defending malpractice suits. An action of this description brought against a physician does not only affect him personally, but upon his victory or defeat depend to a certain extent the good name and financial position of his medical brethren at large. This being so, it is reasonable to expect that every effort will be put forth by the accused to win his suit, as he is as a matter of fact fighting in the interests of the entire medical profession. But unfortunately it often happens that the money necessary to employ the best measures to insure success is lacking, and that consequently irreparable injury is done to physicians throughout the country. Dr. Donald B. Pritchard, writing in the *St. Paul Medical Journal*, July, proposes that a medical defense union, formed on the lines of that now in existence in England, should be established in this country. His idea is to organize a mutual association, the membership of which should be confined to those who belong to the state or some properly organized medical society. In order that the organization might be of the highest standing, it would not be proper to defend one guilty of gross malpractice. That this might be accomplished, every case should be submitted to a standing committee, who after a thorough examination would decide whether or not it would be proper for the association to defend. If the decision is not satisfactory to the member, then a board of arbitration should decide the matter. When the association undertakes the defense, the member involved should be pledged to be absolutely guided by it in the conduct of the case, and that it should not pay any part of the verdict, simply incurring liability for all expenses of the trial. Dr. Pritchard says that he has communicated with a number of well-known lawyers, and that they all say that there is no legal bar to such an association, and that there is no more likelihood of juries being adversely influenced than in the case of any other corporation. The suggestion is at least worthy of consideration, and the good work done by the English Medical Defense Union should act as encouragement for the establishment of a similar organization in this country.—*New York Med. Record*, Sept. 15.

[Would it not be more economical, and far better, to have each state society take up this as one of its duties to its members than to organize an association especially for the purpose as suggested above? Ed.]

Opinion of Medical Expert as to Cause of Death.—The Supreme Court of South Carolina says, in the case of State vs. Foote, that it is very common practice to allow a medical expert to state his opinion as to the cause of death, based on his own personal observation. And it holds that, while it is quite proper that the jury, as far as practicable, should be informed as to the facts or circumstances on which the opinion is based, it is not error to permit such expert opinion when it appears to be based on the witness' personal observation. If the objecting party desires, he may, on cross-examination, it explains, develop all the circumstances inducing the opinion which are capable of reproduction to the jury, and thus test the value of the opinion. But a hypothetical statement of facts as the basis for the opinion of a medical expert as to the cause of death, the court holds, is not necessary when the opinion is based on the personal observation or examination of the witness. Then, exception was taken, in this case, a prosecution for murder, to the reason which the trial judge assigned for refusing to grant a new trial for insufficiency of evidence, namely, "that, if the doctor had stated that the death was not caused by the wound, the jury had the right to disregard the testimony and find that the wound caused the death of the deceased." Still this, the court holds, did not constitute error of law. A circuit judge, it adds, is not bound to set aside a verdict, even if the jury in reaching its conclusion may disregard the opinion of an expert.

Witness Not Allowed to Exhibit His Own Injury.—In the case of the Grand Lodge, Brotherhood of Railroad Trainmen, vs. Randolph, certain medical witnesses for Randolph testified, in effect, that a fractured leg never gets well, and that a person who has suffered such a fracture will be disabled from performing train service on railroads. The fraternal benefit society named sought to dispute this testimony by the experience of one of its witnesses, and by the exhibition of his leg to the jury. This witness was permitted to testify that his ankle had been crushed and injured as seriously as Randolph's leg had been, and that it had so far healed that he was still able to perform his duties in the train service of the railroad company. But he was not allowed to exhibit his injured ankle to the jury. In this the Supreme Court of Illinois holds that there was no error. It says that it is obvious that the point at issue was the extent of the plaintiff's (Randolph's), and not of the witness', injuries, and that to have permitted the close scrutiny requested into the nature and extent of the injury to the witness' ankle would have raised a collateral issue, and diverted the minds of the jury from the issues submitted to them. And the supreme court affirms a judgment holding that Randolph was permanently disabled by being thrown from a locomotive engine and having the bones of his right leg broken, so as to be entitled to recover the amount stipulated in the constitution of the society for a total permanent disability.

County Association Entitled to Fines.—Section 153 of chapter 398 of the laws of New York of 1895 provides that "when any prosecution under this article (for practicing medicine without lawful registration as a physician) is made on the complaint of any incorporated medical society of the state, or any county medical society entitled to representation in a state society, the fines, when collected, shall be paid to the society making the complaint," etc. In the case of the New York County Medical Association vs. the City of New York, the right of the former to such a fine, which had been collected in a case where it had made complaint, was tested. The association showed that it had been since 1890 a duly incorporated society of the state of New York, entitled to representation in the New York State Medical Association, which was incorporated in 1884, and that the state association is the accredited society in the national body of physicians known as The American Medical Association. Such being the case, the Supreme Court of New York, New York County, holds that the New York County Medical Association meets all the requirements of the act of 1895 above mentioned, and that there appears to be no solid legal reason why it should be excluded from the benefit of its provisions. "Association" and "society," the court holds, are convertible terms. To this it adds that the statute was not enacted for the benefit of any particular corporation, but for "any incorporated medical society" entitled to representation in the state society, and that it was passed to protect the public from illegal medical practitioners, and that the more numerous the informers and rigid the prosecution the better for the public and the medical profession. Nor does the court yield assent to the argument that the act was for the exclusive benefit of three societies—the regular, homeopathic and eclectic—because they were named in certain prior acts, and possess certain rights which the New York County Medical Association does not possess.

Societies.

Coming Meetings.

New York State Medical Association, New York City, Oct. 16-18.

American Public Health Association, Indianapolis, Ind., Oct. 22-26.

Medical Society of Virginia, Charlottesville, Oct. 23.

Southern Surgical and Gynecological Association, Atlanta, Ga., Nov. 13-15.

Oklahoma Territory Medical Society, Oklahoma City, Nov. 15.

The Tri-State Medical Association of Mississippi, Arkansas and Tennessee, Memphis, Nov. 13-15.

The Seneca Falls (N. Y.) Medical Association was organized September 26, with the following officers: Dr. Frank M. Severson, president; Dr. Frederick W. Lester, vice-president; Dr. Hubert Schoonmaker, secretary and treasurer.

The Malden (Mass.) Medical Society, at its annual meeting, September 18, elected the following officers: Dr. Charles E. Prior, president; Dr. Charles D. McCarthy, vice-president; Dr. Frank W. Plummer, treasurer, and Dr. William J. Weeks, secretary.

The Aberdeen (S. D.) District Medical Society, at its annual meeting at Aberdeen, September 22, elected the following officers for the ensuing year: Dr. William Edwards, Bowdle, president; Dr. Frank Miller, Aberdeen, vice-president; Dr. George E. Countryman, Aberdeen, secretary and treasurer.

The Bourbon County (Ky.) Medical Society was organized in Paris, September 20, and the following officers were elected: Dr. Washington Fithian, Paris, president; Dr. William V. Huffman, Millersburg, vice-president; Dr. Frank L. Lapsley, Paris, secretary, and Dr. Silas Evans, Paris, treasurer.

The Baltimore County (Md.) Medical Association held its regular meeting September 20 at Towson. Dr. William S. Gardner, Baltimore, read a paper on "Uterine Hemorrhage," and cases were reported by Drs. William P. E. Wyse, Pikesville, Charles G. Hill and L. Gibbons Smart, Baltimore; H. Burton Stevenson, Rider; R. Percy Smith, Sunny Brook, and Jackson Piper, Baltimore.

The Franklin County (Vt.) Medical Society held its semi-annual session at Swanton, September 27. An address was delivered by the vice-president, Dr. Edmund T. Brown, Montgomery Center. Dr. Clarence E. Allen, Swanton, read a paper on "Gonorrhea, Its Influence on the Uterus and Its Appendages." Papers were also read by Prof. John B. Wheeler, Burlington, and Dr. Harlow E. Dunton, Swanton.

The St. Joseph County (Ind.) Medical Society met in South Bend, September 25. Dr. John B. Berteling, South Bend, made a report of the meeting of the Kankakee Valley District Medical Society at Hammond; Dr. George W. Van Benschoten, South Bend, read a paper on "The Relation of General Health to the Eye and Its Diseases," and Drs. Fred P. Eastman, Charles Stoltz and others reported cases.

The North Central Ohio Medical Society held its seventy-sixth quarterly session at Mansfield, September 28. Papers were read by Dr. Feorus F. Lawrence, Columbus, on "Pelvic Suppuration"; Dr. James B. Herrick, Chicago, on "Some Points in the Diagnosis of Gall-Stones"; Dr. William D. Hamilton, Columbus, on "The Dangers of Delay in Cases Having Surgical Possibilities"; Dr. Albert F. Hyde, Shelby, "Brief Talks on Various Subjects," and Dr. Adam H. McCullough, Mansfield, on "Hay Fever."

The Golden Belt (Kan.) Medical Society met at Enterprise, October 4, President Dr. James R. Crawford, Salina, in the chair. Papers were read by Dr. Wilber E. Fowler, Brookville, on "A Scientific Poultice;" Dr. Joseph F. Brewer, Minneapolis, on "Etiology and Treatment of Some of the Diseases of the Stomach;" Dr. William Frick, Kansas City, Mo., "More Complications of Gonorrhea"; Dr. Henry M. O'Donnell, Ellsworth, "X-Ray and Its Advantages in Country Practice," and Dr. Charles Hewitt, Wakefield, on "Practice of Medicine in an Early Day." Clinical cases were also reported by other members of the society.

The Saratoga County (N. Y.) Medical Association was organized September 28 at Saratoga Springs, as a branch of the New York State Medical Association. Dr. Tabor B. Reynolds, Saratoga Springs, was made temporary chairman and Dr. Fred J. Ressegine, Saratoga Springs, temporary secretary. Dr. Frederick Holme Wiggin, New York City, stated the objects of the New York State Medical Association and the benefits to be derived from affiliated county organizations. The following officers were elected: Dr. Frank A. Sherman, Ballston Spa, president; Dr. George F. Comstock, Saratoga Springs, vice-president; Dr. John F. Humphrey, Saratoga Springs, secretary, and Dr. William E. Swan, Saratoga Springs, treasurer. It was decided to adopt the code of ethics of The American Medical Association and to request the council of the State Medical Association to accept the Saratoga County Association as an affiliated branch.

The Idaho State Medical Society held its eighth annual meeting at Boisé October 4 and 5, conjointly with the autumnal semi-annual meeting of the Southern Idaho Medical Association. President Dr. Ed E. Maxey, Caldwell, in the chair. Papers were presented by Dr. Hubert A. Castle, Pocatello, on "Interutero-placentary Hemorrhage;" Dr. Lucien P. McCalla, Boisé, on "Hydraulic Pressure a Means to Open the Common Duct, Which Remained Closed After Removal of Impacted Gall-Stone;" Dr. R. C. Coffey, Portland, Ore., on "A Method of Retaining a Fixed Dressing for Fracture of the Humerus;" Dr. C. E. Worthington, Mullan, on "Reciprocity Between State Medical Examining and Licensing Boards;" Dr. Harry D. Niles, Salt Lake City, Utah, on "The General Practitioner and the Specialist;" Hon. E. J. Dockery, Boisé, on "Physicians as Expert Witnesses;" Dr. Edwin F. Guyon, Montpelier, on "The Proper Method of Using the Sound in Cases of Urethral Stricture;" Dr. Carl Schulin, Helena, Mont., on "Homatropin in the Refraction Room;" Dr. Warren D. Springer, Boisé, on "Position in After-Treatment in Abdominal Operations"; Dr. Michael A. Hughes, Salt Lake City, Utah, "Report of Some Cases;" Dr. Alexander Hunter, Kendrick, "Report of a Case of Tetany," and Dr. Ed E. Maxey, Caldwell, retiring president, delivered an address on "The Clinical Importance of Examining the Blood."

The Association of Assistant Physicians of Hospitals for the Insane held its eighth annual session at the Central Indiana Hospital for the Insane, Indianapolis, September 26, 27 and 28. Papers were read by Dr. W. A. McCorn, on "Genesis of Hallucinations"; Dr. George Boody, Independence, Ia., on 'Katatonia"; Dr. Fred L. Pettijohn, Indianapolis, on "Asexualization as a Means of Prevention"; Dr. Vaclav Podstata, Hospital, Ill., and August F. Lemke, Chicago, on "Delirium in its Various Forms, and Special Reference to the Differential Diagnosis and Prognosis"; Dr. Emmet F. Enos, Hospital, Ill., on "A Case of Punctured Wound of the Brain"; Dr. William MacLake, Ann Arbor, Mich., "Report of a Case of Diabetes, with Remarks on Treatment"; Dr. John B. Briggs, Jr., Baltimore, on "The Systematic Relations of Bacteria and the Infectious Diseases"; Dr. Theophile Klingman, Ann Arbor, Mich., on "The Pathology of Incipient Insanity"; Dr. Albert M. Barrett, Independence, Ia., on "Pathology," and Dr. Irwin H. Neff, Pontiac, Mich., on "The Use of Hypnotics and Sedatives in the Insane." The last day of the session was occupied by the discussion of the developments in the clinical study of psychiatry. The following officers were elected: Dr. Fred L. Pettijohn, Indianapolis, president; Dr. Vaclav Podstata, Hospital, Ill., vice-president; and Dr. Irwin H. Neff, Pontiac, Mich., secretary and treasurer.

San Francisco County Medical Society.

Regular Monthly Meeting, Sept. 18, 1900.

President Elmer E. Kelly, M.D., in the chair.

ETIOLOGY AND SYMPTOMATOLOGY OF RICKETS.

Dr. William Fitch Cheney presented a paper on this subject. It affects not only nutrition of bone, but of all the soft tissues of the body. The most important causative factor is deficiency of fat in the food. A loss of proteids is also a causative factor, for if fat and proteids are both deficient, rickets is more apt to occur than if fat alone is deficient. The probability of the disease is greater also if an excess of carbohydrates is present with a deficiency of fat, and it is for this reason that rickets is so often seen to occur in infants fed on condensed milk. Another important factor is poor hygienic surroundings.

The sweating of the head so often seen in infants while sleeping at night is a symptom of great importance, and should always make the practitioner suspicious of this disease. Restlessness at night, constipation and delayed or irregular dentition are also important symptoms. The enlargement of the epiphyses of the long bones, the rosary, which is very prominent in some rachitic children, should be looked for. The delay in closure of the anterior fontanelle and the square box shaped head are evidences of the development of rickets. The children usually complain of tenderness of the whole body, dislike being carried, and sometimes cry out in being lifted or handled. Flabby muscles and ligaments are frequently overlooked, but are often an evidence of rickets in children slow in beginning to walk. The protuberant abdomen is seen early. There is a tendency to gastrointestinal bronchopulmonary catarrh. There are many symptoms referable to the nervous system. Rickets is one of the great predisposing causes to convulsions, and should always be looked for. Laryngismus stridulus is usually due to this affection, and the tendency on the part of an infant to hold its breath, even until it is black in the face, usually occurs in rachitic children. By these symptoms one can recognize this disease before deformities of bone occur, when it may be possible to prevent them.

THE ETIOLOGY AND DEVELOPMENT OF DEFORMITIES OF THE SKELETON IN RICKETS.

Dr. H. M. Sherman confined his remarks to a consideration of those types of the disease ordinarily seen in California, excluding the severer forms sometimes seen in Eastern and European clinics. That moderately severe cases are seen here is evidenced from the photographs which he presented. Craniotabes is very rare here. It is due to deficient ossification, plus the pressure of the head on the pillow or on the bed; gravity then is one cause of the thin bone and the flattened occiput, the skull not being strong enough to bear its own weight, and that of the contained brain. Deformities of the skull are common; most frequent is the somewhat flattened vertex, with the depression at the anterior fontanelle; next is the flattened occiput, due to prolonged recumbency. In cases of cranial asymmetry he suspects rachitis. Deformities of the thorax are due to muscular force on one side and atmospheric pressure on the other, together with gravity. If the child has rickets early and spends much time lying on its back it would get the broadening of the thorax and the lessening of its depth. If the rickets came a little later, when the child was already sitting or standing, the atmospheric pressure would flatten the ribs anterior to the angle, and by so doing would throw the anterior end forward, carrying the costal cartilages. Whether the sternum were prominent or depressed would depend on the strength of the costal cartilages. If strong enough, the sternum would be carried forward with them; if weak, the sternum would be depressed by atmospheric pressure. The transthoracic groove—Harrison's groove—marks on the outside the attachment of the diaphragm on the inside. As this muscle pulls, the resistance offered by the ribs is less than that offered by the distended abdomen, and instead of the abdominal contents being forced down, the ribs are drawn in; the lowest ribs are however, tilted outward by the distended abdomen, and this gives them their flare, and makes the lower boundary of the Harrison groove. Ordinarily the deformities of the thorax are symmetrical. He regards scoliosis as a deformity of the rachitic thorax. He has never seen a scoliotic that did not show obvious marks of a rachitis, so that the real cause of the deformity of youth and of adolescence must be looked for in the dietary of infancy. It is not common to see deformities of the arms or forearms apart from enlargements of the wrist epiphyses, and some slight increase in the natural curves of the bone. The deformities of the trunk and upper extremities are not of great surgical interest, as they usually do not require correction by surgical methods. The deformities of the lower limbs often require correction, because they are frequently extreme, and because they interfere with the function of the part.

Coxa vara, or the bending downward of the neck of the femur, is probably often a manifestation of late rickets. The natural curve or spring of the shaft of the femur is frequently increased in rachitic children. If the child has been walking, the body-weight is contributed to the deformity, but it exists in children that have not walked as a result of mechanical action. The curve of the femur may be part of the general curve which reaches from the hip to the foot, the leg bones being curved on about the same radius. This deformity is the common bow-legs. In these cases the knee-joint contributes to the deformity, the relative length of the condyles being disturbed, so that the outer is too long. This increased length is probably because of over-growth of the outer condyle, due to the rachitic congestion of the bone and lack of pressure, for, where the body weight is on such a leg, the force on the convex side of the leg is plainly tensile, and not compressive. Furthermore, the ligaments at the knee in these cases are always lax, so that there is actual separation between the outer femoral condyle, and the outer tibial tuberosity, when the child stands. This condition at the knee is genuvarum. The reverse condition at the knee, or genuvalgum (knock-knees may occur, but it is never part of the general curve, though it may be one of the many deformities. The rachitic child always has a tendency to flat-foot, from structural weakness of muscles and ligaments, but this tendency is increased by the outward curve of the leg bone, their shape tending to transmit an inward thrust to the tarsus, and so to roll it over inward. Serious cases of rigid flat-foot combined with slight excurvation of the leg bones in their lower portion are not uncommon. The author concludes that: 1. Structural weakness in the bone is the essential cause of the skeletal deformities in rickets. 2. The active deforming force is either muscular action, or too great superincumbent weight, or pressure by some external object, or gravity. 3. The bone yields always in the direction of the greater force, and this direction is often determined by the natural shape of the bone, the tendency being to increase normal curves. 4. In some cases where there is no other reinforcing bone, there is a hypertrophy of the deformed bone. to antagonize the deforming force. 5. Symmetrical deformities are characterisitc of rachitis, the similarity of structure of the two limbs, and the similarity of the mechanical conditions in them, tending to produce similar resulting deformities.

TREATMENT OF DEFORMITIES DUE TO RACHITIS.

Dr. I. J. Hunkin presented a paper on the above subject. For deformities of the skull, the ribs and the pelvis surgery offers but little remedy, and these are the forms fortunately rarely seen with us. Under proper care, also, nature proves often fully competent to attend to most of the deformities of the upper extremities, and to a large extent also to the long outward curves of the femora. In the vast majority of cases the surgery of rachitic deformities has relation to changes in the tibia. Surgically, there are three plans of treatment: expectant, mechanical and operative. The expectant method relies largely on the efforts of nature, aided, of course, by the hygienic and medical control of the case. This usually succeeds in mild, and often in medium, degrees of deformity, when the patient is 2 years, and perhaps 3 years of age. The long curves of the femora and humeri are especially amenable to treatment in this manner. The mechanical treatment has two divisions: ambulatory and recumbent. The ambulatory, meaning the attempt to correct the deformity by the wearing of splints and braces during locomotion, is to be condemned. There is no doubt that any of these deformities can be corrected by mechanical applications in the hands of the surgeon in young children, and perhaps in older children, if the patient is kept recumbent during treatment, but even here it is a waste of time and energy. If the child is to be confined to bed during the treatment it is far better that the proper operative procedure should be adopted, the deformity corrected at once, after which simple retentive splints are alone necessary. The patient needs no special care and in six or eight weeks is up and about and in as good condition as he would be in as many months with apparatus alone. There are three operative procedures: osteoclasis, osteotomy and osteoectomy. Osteoclasis is the simplest operation and most generally applicable in the great majority of cases, especially where the deformity involves most of the shaft of the bone, or where the summit of the curve is not close to a joint. The author uses for this purpose of the osteoclast of Grattan. While it is generally taught that the force should be applied at the summit of the greatest concavity, he usually prefers the point of the greatest convexity, believing that he gets earlier reposition, and less danger of twisting the bone before the blow is delivered by the instrument. Osteotomy is performed with the regular osteotome. The leg being supported on a sand-bag, the incision is made with the osteotome, the edge being held perpendicularly to the leg and the division being made by forcing the blade through the soft tissues with the hand, or preferably with a sharp tap of the mallet. When the bone is reached the blade is rotated in the tissues until the cutting edge is across the bone, into which it is driven to the desired depth. No attempt is made to cut through the whole bone, for division of 3/5 of the circumference allows ready reposition of the deformity. The osteotome being removed, the proper correction is made manually. The incision receives no attention, except being covered with a clean pad. The position secured is maintained with a plaster-of-paris splint. Union is usually prompt and satisfactory. Osteoectomy, or osteostomy, is performed through an open incision and consists in removing a wedge of bone from the apex of the deformity, the base of the wedge being from the convex surface. This wedge is resected with the chisel, or the osteotome, and the mallet. No bone suture is necessary. The periosteum and skin are closed separately and a plaster-of-paris splint applied. The union after all these operations is generally prompt and relapse is very infrequent. For deformities of the shaft at any point, when the apex of the curve is 5 cm. or more from the joint, osteoclasis is the operation par excellence in the great majority of cases. Close to the joint line osteotomy is always to be preferred.

DIAGNOSIS AND TREATMENT OF RACHITIS.

Dr. E. G. Frisbie called attention to the fact that scorbutus and rickets may co-exist, and that the diagnosis of the latter can be made by the absence of the intense pain in the region above the epiphyses, and if teeth are present, by the absence of ulcerative stomatitis. From acute rheumatism rachitis may be differentiated by reason of the less acute pain and absence of any considerable fever and joint swelling; from Pott's disease, by the longer spinal curvature and less rigidity of the spine, although this differentiation may in some cases be very difficult. From osteomalacia the differential diagnosis is impossible, but happily this disease is so rare in this region that it may practically be excluded. The constitutional treatment of rickets should consist of hygienic, dietetic and medicinal measures, Since by far the larger number of rachitic patients are among the poor, it becomes of the first importance to see that the hygienic conditions are improved. The dietetic management is important both as a prophylactic and a curative measure, and in the nursing infant this should begin with attention to the diet of the mother. Artificially-fed infants should be fed on a modified cows' milk. For older children, the author advises an abundance of fresh butter spread upon bread, and the continuance of the use of a larger proportion of milk, as well as beef juice and meat broths.

The medicinal treatment consists of the careful regulation of the bowels and the use of cod-liver oil, which the author considers the most generally useful drug. Phosphorus he also considers beneficial in doses of 1/200 to 1/100 of a grain for children of 2 to 6 years, and smaller doses to younger children. For the anemia accompanying the disease, the syrup of the iodid of iron is the preparation of his choice.

American Electrotherapeutic Association.

Tenth Annual Meeting, New York City, September 25-27, 1900.

Dr. Walter H. White, Boston, in the chair.

ELECTRIC LIGHT AS A THERAPEUTIC AGENT.

Dr. Charles O. Files, Portland, Me., said that the electric light acted by impairing the vitality of the bacilli, partly by the action of the light per se, and in part by the incidental generation of ozone. The treatment was preferably given in connection with an arc-light cabinet. In all of the incipient cases of tuberculosis in which he had tried this method, there had been improvement.

Dr. Wolff Freudenthal, New York City, read a paper on "Electric Light; Its Physiological Action and Therapeutic Value in Tuberculosis of the Throat and Lungs." He discussed the evidence at hand concerning the germicidal action of light, and reported several cases in illustration of what might be accomplished by the electric-light treatment.

A REPORT ON THE PRACTICAL VALUE OF CROTTE'S METHOD OF TREATING CONSUMPTION.

Dr. Egbert LeFevre, New York City, presented this report. It was founded on a three-months trial of the method in St. Luke's Hospital with the object of fairly testing the claims of the inventor. To that end careful records were kept of both the local and general condition of all the patients taking the treatment both before and after. Not one of the cases in the first stage of the disease showed any abatement of the local process, and in two of these patients the change for the worse was so apparent after two weeks that the treatment was discontinued. Three of this series showed some temporary improvement, but no more than they had exhibited during the stay in the hospital under hygienic and dietetic treatment. A case of tuberculosis of the glands was made so much worse by the irritation set up by the iodin and by the electrical application, that the glands broke down, necessitating an operation. Coincident with this breaking down of the glands there was a rapid increase of the disease in the lungs and the case ran a very rapid course. In the advanced cases the treatment apparently did harm. The treatment consisted in giving the patients static electricity while seated on an insulated stool. In addition to this a towel moistened with a solution of formalin was placed on the chest, and a solution of iodin in spirits of camphor was painted over the chest at the site of the pulmonary disease. When the pathologist of the hospital reported that he was unable to find, after examination of the patient's secretions, any evidence of absorption of either iodin or formalin, Mr. Crotte retorted that he was not competent to carry on such an investigation. To be perfectly fair, Crotte was then allowed to have this part of the work done by his own chemist, but the latter was also unable to find evidence in support of Crotte's contention and boasted claim that these substances were driven into the patient's system by cataphoresis. Crotte's claim having thus fallen to the ground, and the clinical investigation having demonstrated the worthlessness of this method of treatment, it was abandoned

Dr. William J. Morton, New York City, said he had gone to St. Luke's Hospital to find out the Crotte method, and had been unfavorably impressed by what he had seen there. A patient was being treated at the time with static electricity obtained from a modern American machine. On the other side of the room stood a French ebonite plate machine, from which he could elicit no sparks, yet he was informed that this French machine was their main reliance in giving the Crotte treatment, the other machine having "no cataphoric power!" Dr. Morton went on to say that he was not aware that vapors could be introduced into the body by cataphoresis, and if the Crotte method were to receive any further attention from the scientific physician it was essential that a clear understanding should be had of the electrophysics on which it is based. At his suggestion, the association appointed Drs. William J. Morton, Robert Newman and Emil Heuel, New York City, a committee to settle definitely this vital question.

GENERAL WORK OF A GYNECOLOGIST.

Dr. Fred H. Morse, Melrose, Mass., read a paper on the above subject. He said electricity was invaluable in making a diagnosis of deep-seated pus formations, and electrical treatment in his hands had been most satisfactory in cases of metritis, endometritis, subinvolution, displacements, ovarian neuralgia and painful menstruation. He preferred to use large electrodes made of asbestos cloth, and looked on an amperemeter and a good high-tension faradic battery as necessary parts of the office armamentarium of the successful physician.

THE MORTON WAVE CURRENT.

Dr. W. B. Snow, Atlanta, Ga., said it was the only current of very high potential that could be passed through the body with little or no discomfort, and the fact that it penetrates every part of the body gives it a unique position as a therapeutic agent. This current when applied to the human subject produces: 1, a marked lowering of arterial tension; 2, a reduction in the frequency of the heart's action, with an increase in the volume of the pulse; 3, increased oxidation and metabolism; 4, a sense of drowsiness, and 5, a sense of fatigue if the treatment is unduly prolonged. It was most important to repeat the application, in cases of neuralgia before the pain has returned with an degree of severity. For sprains and bruises it is unexcelled.

Dr. William J. Morton, New York City, also made some remarks on this current. He believes that it embodies all that is to be obtained from the static machine in current form. The treatment is more agreeable than with the static induced current, it is just as easily localized, and its action is more widely distributed in the body. It produces marked analgesic effects.

Dr. C. R. Dickson, Toronto, Dr. Lucy Hall-Brown, Brooklyn; Dr. Margaret A. Cleaves, New York City, and Dr. Walter H. White, Boston, all spoke favorably of the action of this current in neurasthenia, neuralgias, neuritis, rheumatoid arthritis and other diseased conditions.

THE CAUSES OF SOME CASES OF NEURASTHENIA AND THEIR TREATMENT.

Dr. Francis B. Bishop, Washington, D. C., read this paper. As a result of his studies of the urine in cases of neurasthenia he had learned that there was quite commonly a diminution in the urea and an increase in the phosphates. The object of treatment, he reasoned, should be to promote such changes as result in the formation and elimination of a larger quantity of urea. Muscular exercise is good, but as these patients are already fatigued, he selected electricity as the agent best suited for his purpose. The treatment begins with mild galvanization of the brain and spinal cord, and is followed by general faradization and finally by exposure of the whole body to the static breeze by the use of an apparatus which he calls an ozone cage. This last application he finds particularly soothing and pleasant to these patients.

X-RAY PHOTOGRAPHY.

Dr. E. R. Corson, Savannah, Ga., presented a paper on this subject. He insisted that good skiagraphs of bones should give good detail in the bones themselves. He recommends using a coil giving only an 8 or 10-inch spark, and using all the current the X-ray tube can stand. All his negatives are intensified until they are very black and dense.

ELECTRICITY IN BRAIN FAILURES.

Dr. D. R. Brower, Chicago, read a paper on the above subject. He finds that these cases are very often associated with a dilated stomach, and here he strongly advises the daily use of intragastric galvanization, using Einhorn's electrode. In addition he resorts to galvanization of the brain, using a current of one or two milliamperes for two minutes. This is followed by transverse and bulbar galvanization, and lastly by static insulation.

ELECTROTHERAPY OF INSANITY.

Dr. Alfred T. Livingston, Jamestown, N. Y., described his very favorable experience with the use of electricity in cases of melancholia—a method almost unknown to those who have most to do with insanity. The treatment is founded on the theory that insanity is largely dependent, in the first instance, on circulatory changes in the brain. A current of 10 to 15 milliamperes is used on the lower pair of sympathetic cervical ganglia, one of 8 or 10 milliamperes on the second pair, and one of 5 or 8 milliamperes on the upper pair, the electrodes being carefully slid along so as not to produce a break in the current.

The following officers were elected: President Dr. Ernest Wende, Buffalo; vice-presidents, Dr. Fred H. Morse, Melrose, Mass., and Dr. D. R. Brower, Chicago; secretary, Dr. George E. Bill, Harrisburg; treasurer, Dr. R. J. Nunn, Savannah; chairman of executive committee, Francis B. Bishop, Washington. The next annual meeting will be held in Buffalo, beginning the first Tuesday in September, 1901.

California Academy of Medicine.

Monthly Meeting, September 25, 1900.

ECTOPIC PREGNANCY.

Dr. J. Henry Barbat exhibited both Fallopian tubes removed from a patient who was taken, twenty-four hours previous to the operation, with severe pain in the abdomen, accompanied by pallor and faintness. She had missed her menses the month before, after having been regular for four years, and had felt that something was wrong with her, as she had some pain in the pelvis, and thought she might be pregnant. A diagnosis of ectopic pregnancy was made and operated on immediately. When the abdomen was opened fully a liter of blood poured out, containing a number of clots. The left tube was lifted out of the belly and found to contain a large quantity of blood, its fimbriated extremity being completely occluded. It was removed, leaving the ovary, which was normal. The right tube was then lifted out and found ruptured near the distal end. It was removed and, on opening it, a fetus of about three weeks was discovered. The left tube contained fluid blood and a decidua which formed a closed sac at both extremities of the tube.

He describes a second case of tubal pregnancy in which the fetus was not more than two weeks old. The menses had been delayed several days, and when they appeared, kept drizzling longer than usual. The patient also noticed a sharp pain in the pelvis on the right side, but otherwise felt perfectly well. A diagnosis of ectopic pregnancy was made and the tube removed, which was not yet ruptured, but was leaking blood from its fimbriated end. A peculiar coincidence is that the patient's sister died a few years ago from ectopic pregnancy.

A CASE OF LEPROSY.

Dr. D. W. Montgomery reported a case of a white woman who contracted leprosy in San Francisco. This woman presented herself on Nov. 14, 1899. She was 50 years of age and was suffering from paralysis agitans. Her father still lived and was 80 years of age. Her mother had died three years previously at the age of 75. On coming from Ireland to San Francisco, in 1870, she married an Irishman, who had lived in Ireland, Boston and San Francisco, and nowhere else. He had died in 1882 from hemorrhage of the stomach. Patient said her husband had never had any blotches on his skin. She had had two children and one miscarriage. There was a group of smooth, glistening, firm, prominent tubercles on the left cheek, and there was a tubercle near the vermilion border of the upper lip, to the left of the philtrum. There was one tubercle on the nose tip, and the lobes of the ears were infiltrated and nodular, and there were leucoplasia-like patches on the roof of the mouth. There were tubercles or red maculæ scattered over the skin of the upper and fore arms.

There was no demonstrable enlargement or tenderness of the right ulnar or median nerves, but the left ulnar nerve was slightly enlarged and very sensitive to touch. The skin of the backs of the hands and, to a slight extent, of the left fingers was swollen, smooth, waxy-looking, and had tubercles scattered in it. The sensations of touch and pain were normal in both upper extremities. Both legs were swollen, with red blotches and tubercles in the skin. Microscopic examination was made of the juice squeezed from one of the tubercles, and a large number of lepra bacilli were found.

The woman was said to have subsequently died of pulmonary tuberculosis.

This is the second case of leprosy in a Caucasian that he had ever seen during a practice of over fourteen years in San Francisco. He assumes from this that while the danger of the spread of leprosy in California among the whites is not pressing, it must be remembered that it is a disease that slowly and tenaciously invades a country, the invasion to become appreciable often requires several generations. In the fulness of time, when many lepra centers are established, the invasion seems to be more rapid.

Dr. J. Henry Barbat thought there was some possibility of the nodes on the skin of this patient being tuberculous, as the patient had died of pulmonary tuberculosis. The similarity of the lepra bacillus to the bacillus of tuberculosis might account for the apparent finding of the lepra bacillus in the tubercles of this patient.

Dr. Philip King Brown said that the bacilli being [illegible] the skin in large numbers would, in itself, be diagnostic of leprosy. In postmortem examinations he [illegible] large numbers of the bacilli [illegible] through the skin [illegible] the nodules.

Dr. Montgomery said that [illegible] leprosy die of tuberculosis. He [illegible] tiating between the lepra [illegible] sis. The bacillus tuberculosis [illegible] of lepra, which, by the [illegible] forms.

Cleveland Medical Society.

Regular Meeting, September 14.

President Dr. Henry S. Upson in the chair.

Dr. P. M. Foshay introduced a resolution, which was unanimously adopted, requesting the State Board of Medical Registration and Examination to raise the standard which it has prescribed for those wishing to enter on the study of medicine.

POPLITEAL ANEURYSM.

Dr. Carl A. Hamann presented a case of popliteal aneurysm which had been cured by digital pressure of the femoral artery for forty-six hours. The aneurysm had been about the size of a hen's egg, and had been accompanied by the usual signs, that is, a distinct bruit, expansile pulsation, some edema of the leg, and also distension of the superficial veins. Operation was contraindicated by the existence of a dilated aorta and a hypertrophied left ventricle. He said that digital compression is the best way of treating popliteal aneurysm, and this should always be tried before an operation is resorted to.

PRACTICAL POINTS ON THE MANAGEMENT OF LABOR.

Dr. Frank S. Clark read a paper on this subject, in which he emphasized the importance of all antiseptic precautions in obstetric work, and suggested that obstetrics was neglected by medical societies. He stated that in all instances puerperal sepsis is due to lack of cleanliness on the part of the physician or the nurse. He suggested that the fees in obstetrics are much too low, which is probably one reason for which physicians are inclined to be somewhat careless in their work, particularly in the matter of making sufficient visits after confinement to be personally assured that their patient is doing well.

Dr. Harris G. Sherman, in the discussion, said that ophthalmia neonatorum is one of the great causes of blindness and can always be avoided by the physician himself washing out the eyes with some simple antiseptic. Nitrate of silver, as often used, is too strong.

Dr. Ralph J. Wenner thought that obstetrics was not more neglected than other branches of medicine. He had seen ophthalmia neonatorum in a few cases arise under what appeared to be perfectly aseptic conditions. While there is some carelessness in obstetric work, no sweeping charges against the entire general profession were justified.

Dr. George S. Smith thought with the essayist that there is a great deal of carelessness on the part of the general practitioner and the teaching of obstetrics in medical colleges. He was convinced that fees for this work in the Western cities are much too low.

Dr. Clark, in closing, agreed with Dr. Sherman's remarks concerning the care of the infant's eyes. In reply to a question by Dr. Joseph E. Cook, he stated that he had never attempted repair of a cervix immediately after labor, for fear of infecting the uterus.

THIOSINAMIN IN CORNEAL OPACITY.

Dr. Harris G. Sherman reported thirty-three cases of corneal opacities treated by thiosinamin given in one-grain doses three times a day. He had secured favorable results, although not complete absorption of the opacities. He was convinced that the drug possesses very marked power of absorbing overgrowth of connective tissue. He urged others to use the drug in suitable cases to determine its further value.

Dr. William E. Bruner said that he had used the drug in a few cases of corneal opacity, and recalled one which was markedly benefited.

Dr. John B. McGee said that the practical point brought in this paper was the use of the drug in absorbing abnormal growths of connective tissue. He had had some favorable results with it and some that were not so favorable.

Dr. Sherman, in closing, said that the one most interesting fact in regard to the drug is its action in absorbing lupus and scars of a deep-seated nature. Some investigators have reported most favorable results with it in such conditions. Glandular growths have also been successfully treated with it. In his cases, while complete absorption did not result in every instance, the vision was very markedly increased in all.

MYOMA COMPLICATING LABOR.

Dr. John J. Thomas reported a case of labor complicated with fibroid tumor, in which great difficulty was experienced in determining the conditions during labor, and in which the tumor disappeared completely afterward without operation or treatment of any kind. He also reported a case of acute catarrhal laryngitis in a child 4 weeks old, accompanied by severe and prolonged spasm of the larynx.

Chicago Medical Society.

October 3, 1900.

President James H. Stowell, M.D., in the chair.

Dr. John B. Murphy read a paper on "Tuberculosis of the Testicle, With Special Consideration as to Its Conservative Treatment." It will appear in an early number of The Journal.

THE VALUE OF ANTISEPTIC NEBULÆ IN PULMONARY TUBERCULOSIS.

Dr. Homer M. Thomas followed with a paper on the above subject. At the outset the author reviewed the various methods of cure for tuberculosis which have been brought forward since 1882. A candid consideration of all those methods of treatment emphasizes his belief that they are merely collateral agencies; that the fundamental processes of cure are established by nature, not by the physician. The author's earlier papers were devoted to a review of animal experimentation. These progressively demonstrated the presence of antiseptic nebulæ from the nasal passages down to the throat, trachea and larger bronchial tubes. Additional animal experimentation microscopically showed the presence of oil globules in the pulmonary alveoli. The following benefits seem to the author to be established, as a reason for the general use of antiseptic nebulæ in the treatment of pulmonary tuberculosis:

1. The respiratory capacity, which is very limited in tubercular patients, is increased.
2. The catarrhal condition of the air-passages is diminished, thereby aiding a better introduction of air into the lungs.
3. The pulmonary passages are kept in an aseptic condition, and the danger of new invasion by tubercle bacilli is minimized.
4. The marked relief of cough and dyspnea.
5. The alimentary tract is undisturbed by drugs, giving ample opportunity for the increase of vital resistance by suitable diet and constitutional treatment.
6. The treatment of pulmonary tuberculosis by the inhalation of antiseptic nebulæ is rational and practicable.

PRESSURE THERAPY IN GYNECOLOGY AND OBSTETRICS.

Dr. Palmer Findley said that the method which he proposed is a modification of Freund's so-called "resorption cure." It consists of the introduction of a Carl Brun's' colpeurynter into the vagina, filled with 500 to 1000 grams of quicksilver. Over the abdomen is placed a bag of shot weighing one to three pounds. The patient is placed on her back or side, depending on the site of the pelvic exudate, and the pressure is continued for from one to several hours. The foot of the bed is elevated and the hips are elevated by pillows. The bladder and rectum are first emptied. This treatment is repeated daily until the desired results are obtained. When pain is caused, the pressure is relieved by removing the quicksilver and shot-bag. The danger of continuing the treatment in such an event lies not alone in the discomfort, but in the liability of exciting an acute exacerbation of the subacute or chronic inflammation, and in the dissemination of an unrecognized virulent infection. This is particularly likely in latent gonorrheal infection.

The indications for the treatment are parametritic exudates, particularly those lying low in the pelvis; cellulitic exudates, and in this lesion the treatment is especially applicable, because the exudate lies low in the cul-de-sac or in the broad ligaments, and is therefore directly compressed by the colpeurynter. It is in fixed retroplaced uteri that the method is most applicable. Here, in two or three treatments, the uterus is brought forward by direct pressure from behind and by the stretching of the adhesive bands, and at the same time the posterior vaginal wall is put on a stretch, thus throwing the uterus forward.

The method has lately been advised in retroverted, incarcerated pregnant uteri. Halban reports a reposition of the uterus by a single trial. Incarcerated pelvic tumors may be treated by the same method, if located low in the pelvis.

The method is not recommended as a substitute for massage in all cases. There are cases in which massage is preferable, as, for example, in adhesions attached to the fundus of the uterus, or involving normally placed appendages, but in the majority of instances the procedure is more convenient of application and the results are more quickly gained, requiring days where pelvic massage may require weeks and even months.

AMERICAN.

1. **Nitrogen Gas Injections in Phthisis.**—Loomis has had good results with the method of injecting nitrogen into the pleura, advised by Murphy, in cases of tuberculosis, and reports a series of cases. He has not seen any absolute cures, but has seen an apparent arrest in two cases and no bad results in any. Improvement, especially constitutional, is marked and he finds the injections particularly beneficial in cases of pulmonary hemorrhage.

2. **Electricity and Gynecology.**—The use of electricity is commended by Newman, who finds from his own experience that better results are obtained from it than from any other means in many gynecologic conditions, and the lack of favor with which it is received by gynecologists has not been explained. He thinks we should have better instruction in electrotherapy.

3. **Cirrhosis of the Liver.**—The case reported by Luzzatto shows, he thinks, that alcohol is not the sole cause of cirrhosis of the liver, and that, when it is the cause, the disease is curable, more often the hypertrophic form, but the atrophic form also. It often shows symptoms characteristic of infectious disease. In his case the patient was entirely cured with milk, potassium iodid and diuretics.

4. **Interstate Reciprocity.**—Amberg's paper advocates the co-operation of the profession at large with the confederation of medical examining boards for the purpose of advancing the general interests of the profession. He suggests an interstate reciprocity committee, to be appointed by the national confederation, which will keep in touch with all other similar committees and, if thought advisable, will publish a journal.

5. **Fracture of the Patella.**—Trimble describes his method of operating for fracture of the patella, and claims that by operation only can good results be obtained. The aponeurotic

fringe can be removed only by operation, and if nothing has been interposed at the time of injury, the pressure required to control the contraction of the quadriceps interferes with the circulation and is also unendurable. Fibrous or ligamentous union is the best that can be expected from non-operative measures, and this will permit stretching to such a degree as to produce serious consequences. The operation should not be attempted after the fiftieth year, and other contraindications are diabetes and albuminuria. His method is the use of the wire suture.

6. **Hypertrophy of Deformed Bones.**—Holmes holds that in the second stage of hypertrophic rhinitis there is only one successful treatment, that is, careful surgical interference. He describes and illustrates his method and insists on the comparative importance of the operation. In all cases he removes as little of the edge of the inferior turbinate as possible for restoration of sufficient breathing space and saves as much of the anterior end of the bone as possible, inclining the line rather upward and backward from the lower edge of the anterior end, so as to incline as much as possible of the posterior hypertrophy, the saw having been pushed backward until its blunt tip is in the pharynx.

8. **Umbilical Hernia.**—The conclusions drawn from a comparison of the various methods by Stinson are: 1. That with careful antiseptic precautions, provided the operator is skillful and familiar with the special anatomical and pathological conditions associated, an operation for the cure of umbilical hernia has a mortality of about nil, or less than that associated with the condition previous to the operation. 2. That sterilized chromicized tendon or, in its absence, carefully chromicized catgut, is the most suitable material for buried sutures. 3. That before closing the wound the sac should be removed, the contents cleared out, the edges of the serosa overcorrected and then united with a layer of continuous sutures; the internal ring or opening in the transversalis fascia should be closed by continuous sutures; the internal ring should be reinforced and the remainder of the breach in the abdominal wall closed by uniting the broad edges of the fascia—the linea alba and lineæ semilunares—in two layers, avoiding tension by loosening one or both of the recti muscles from their sheaths, and bringing them together in the median line by sutures to fill and close the gap; the recti muscles are also to be used to close the breach when the fascial layers are atrophied; the skin is closed with continuous stitches without drainage. 4. That in the immense majority of suitable cases the patients are cured by the operation. 5. That the operation described closes the breach in the abdominal wall firmly and durably and without tension; has all the advantages of other operations, and that, having many additional advantages, and fulfilling all the indications for a radical cure, it should be followed by the best results.

10. **Piperazin.**—Aldrich reports two cases in which he thinks that piperazin prescribed in a diurnal of 20 to 25 grains in a large quantity of water was successful in relieving the condition of nephrolithiasis. He suggests the use of carbonated piperazin water in these cases as more agreeable and effective.

12. **Appendicitis.**—The general facts in regard to appendicitis, its tendency to recur, the classification of cases, etc., are discussed in full by Lloyd, and the technique of the operation described. He thinks there can be no longer any question in regard to the advisability of operating. His own experience shows of 160 appendectomies, 4 deaths—a ratio which he thinks will compare favorably with any medical statistics that can be offered and justifies early and radical operation.

13. **Pleural Exudate With Physical Signs of Pneumonia.**—Allyn reports a case of empyema which began with symptoms closely resembling pneumonia—chill, fever, cough, expectoration and physical signs on admission in accordance. At the autopsy there was found a thickened pleura with about 250 c.c. of pus, a fibroid lung with bronchiectasis, and old tuberculous foci in both lungs. There was probably just enough area above the small air-space to act as a resonator for the voice and breath-sounds and transmit them through the dilated bronchus. He asks whether there is any certain way in which the pleural exudate can be recognized and admits that there is no pathognomonic sign. The most important test is, of course, the puncture with a needle, but this may be also misleading, and it is sometimes difficult to obtain fluid, and when found, it may possibly come from a local subphrenic abscess. The X-ray would be of great service.

14. **Pneumonia.**—After an analysis of the cases, the author offers the following general observations: The most frequent predisposing cause of pneumonia is some pre-existing disease. Idiopathic pneumonia may be attributed entirely to depressing influences. Pulmonary inflammations are not only more prevalent in special periods, but the type also is more virulent at certain times. La grippe not only augments largely the number of cases during its prevalence, but has increased also the mortality. The left-sided croupous form has proved more difficult to manage and more frequently passes into phthisis than the other forms. Catarrhal pneumonias, when the apices of the lung are involved, are also associated with delirium. Alcoholism and typhoid do not enter as factors in the mortality of the cases discussed, but both have been observed to retard the stage of resolution and otherwise to lengthen the convalescence. As regards the treatment, he would first use counterirritants, arterial sedatives, antipyretics and anodynes. In the second stage he would cautiously, but vigorously, employ arterial sedatives, antipyretics, and even counterirritants, with the idea of limiting the area of infiltration and hepatization. In his experience it is usually in this stage that the physician is first called, and he found ammonium carbonate and iodid especially indicated, while only sufficient of the antipyretic, as, for instance, sodium salicylate, is employed to keep the temperature well in hand. He seldom uses opium in combination, but alone when indicated. Venesection has been employed twice without special effect on the lung itself. Cuppings to relieve pleuritic stitches were beneficial. In the third stage, where is the greatest danger, antipyretics are discontinued and alteratives, tonics, etc., are employed. When the affected lung is once restored to the normal condition, he thinks the official compound syrup of hypophosphites is serviceable.

16. **Inhibition of the Heart in Diagnosis.**—Abrams summarizes his investigations on the value of inhibition of the heart by forcible contraction of the muscles of the neck as follows: 1. The inhibition maneuver may cause organic cardiac murmurs to become faint and even, in exceptional cases, inaudible. 2. Transmitted murmurs are more amenable to the maneuver. 3. The fainter the murmur, the more easily is it suppressed. 4. When a transmitted murmur can be inhibited the tone which it masks can be auscultated. 5. The heart-tones are less amenable to inhibition than are the heart-murmurs. 6. Hemic murmurs are more readily inhibited than those of organic origin. 7. As a rule, anemic murmurs can be suppressed and their disappearance is marked by the reappearance of tones. 8. Exocardial murmurs are easily influenced by inhibition. 9. When the maneuver is incorrectly executed, the result is to increase the intensity of the murmur owing to increased exertion, which intensifies the heart's action. 10. When often repeated the inhibition murmur is futile owing to over-stimulation of the vagi. 11. In irregular action of the heart or in delirium cordis, the inhibition maneuver, by momentarily inhibiting the rapidity of the heart, renders signal service in determining the time of a murmur, being practically in its effects like the physiologic action of digitalis on the heart. 12. Inhibition maneuvers enable us to determine the condition of the vagi as to cardiac inhibition and guide us in the administration of the cardiotonics.

17. **Hemorrhoids.**—After noticing the treatment of hemorrhoids and advising the ligature treatment, Doyle offers special objections to the use of carbolic-acid injections, which, he thinks, are still sometimes practiced by responsible practitioners.

18. **Ammonio-Formaldehyd.**—Keyes sums up his conclusions as follows: 1. Urotropin seems to be almost a specific

in the treatment of some cases of acute catarrhal pyelitis, uncomplicated. 2. To prove effective it may have to be administered in high doses until the urine is practically clear of bacteria, after which a smaller dose may suffice. 3. In judging the effects of the drug, the centrifuge and microscope should be employed. 4. The dose must not be sufficient to cause pollakiuria and dysuria by irritation of the neck of the bladder. 5. The possibility of such an irritation can not be overlooked, even when very small doses are employed. 6. Urotropin is extremely serviceable as a prophylactic of the various forms of urinary septicemia and urethral chill. 7. Its routine employment both before and after operations on the urinary passages is indicated. 8. The urine containing urotropin occasionally has an escharotic effect upon wounds, which may constitute a contraindication to its employment.

20. **Studies in Metabolism.**—The subjects noted by McCaskey are especially the excretion of urea and uric acid. In urea hypo-excretion we have a depressed condition where the functional and nutritional processes must be stimulated. With increased urea excretion, of which diabetes mellitus is one of the most prominent conditions, the excessive metabolism must be cared for, and if in the excretion strictly within the normal range we still have nutritional disturbances, we should look for toxic conditions resulting from disorder of some principal organ of the body. As regards uric acid, he thinks that the theory of its being derived from the nuclein of the white blood cells is not entirely supported by clinical observation. In one case of splenic myelogenous leukemia he observed that the quantity of uric acid fluctuated widely, and all that he can say as regards these variations is that they indicate a disorder of the normal metabolic processes which has a more or less important bearing on chronic nutritional disorders. Other points of interest found by urine analysis are the presence of leucin and tyrosin and the variations in the quantity of different organic salts, especially the phosphates and chlorids as bearing on the metabolism.

22. **Potassium Iodid.**—The inconvenient effects of potassium iodid occasionally observed are noticed by Somers, who shows that these are sometimes caused by nutritional disease as well as by an apparent cumulative effect in long dosing. The individual variations are very great and we can not consider the tolerance to the drug as indicating the presence or absence of specific infection. The recent explanation of some of the peculiarities of reaction by von Cyon is that the iodid salts circulating in the blood in small doses were changed into iodiothyrin by the thyroid gland and this substance produces reaction; while in large doses they are eliminated by the kidneys in the form of soluble salts. It is to a certain extent possible to prevent the phenomena by the use of drugs such as arsenic and belladonna and by increased dilution of the iodid.

24. **Fracture of the Radius.**—From a study of the X-ray plates of a large number of cases of fracture of the radius, Codman divides the fractures into ten distinct types: 1. Fracture through the base of the styloid process, which does not affect the hand or wrist and which is properly treated by plaster straps around the wrist. 2. Fracture of the inner angle of the lower end of the radius without radical displacement of the hand, and its treatment is similar to the above. 3. Transverse fracture at or a little above the epiphyseal line (in adults) without displacement. Of these there are quite a number. 4. Comminution of distal fragments. 5. Separation of the epiphysis of the lower end which often present themselves with fragments completely reduced, but may show the typical silver-fork deformity. As a rule they are easily reduced, but generally tend to become readily displaced. Careful reduction and fixation in splints or plaster for a couple of weeks is almost sure to produce a good result. 6. This class is quite common. It consists in separation of the epiphysis of the lower end with a chip from the posterior surface of the diaphysis. Fixation and the dorsal pad are enough in most cases. If there is radial displacement cross traction as in Class 8 may also be employed. 7. The impaction of the lower fragments into the shaft is rare, occurring only twice in 140 cases. Unless contraindicated by age, it is better to break up the impaction and use anterior and posterior splints. 8. This class is the typical Colles' fracture and Codman divides it into two forms: *a*, with marked radial displacement of the fragment, and *b*, that in which posterior deformity is most decided. The skiagraphs show both the lateral and anteroposterior view of this fracture. The important point in the treatment is the pulling down and the pushing of the lower fragment over the end of the dorsal edge of the upper. Once reduced it can be kept in place, but has a tendency to slip out when pressure is omitted, and a simple pad of sheet wadding or felt pressed over the dorsal surface of the lower fragment and an anterior pad along the front of the radius about three-fourths of an inch wide and one-fourth of an inch thick are necessary. This latter stops just short of the sharp edge, which is fastened on the arm by adhesive straps before the splints are applied. A posterior splint to the knuckles of the first phalanges and an anterior, to the thenar eminence holds these in position. To control the tendency of the hand to become displaced to the radial side a cross-traction method is used. Two adhesive straps are looped about the wrist in opposite directions, one tending to pull the ulna toward the radial side and the other to pull the fragment with the hand to the ulnar side. These are placed at the same time as the anterior and posterior pads, the splints are held by an assistant, and after putting a circular strap about the upper end of the splint, traction in the opposite direction is put on the lower straps and the ends curled about the splints and caught. This leaves the ulnar side free opposite the ulnar fragment and the radial side free opposite the upper fragment and ensures a good circulation. The fingers and thumb are allowed free movement throughout and the splints are cut off at the wrist at the end of the second week. 9. Stellate fracture of the lower end of the radius with longitudinal fissures extending into the shaft. It has occurred six times, or in 4 per cent. of 140 cases. A simple band around the wrist is the only fixation required. 10. Reverse Colles' fracture, anterior displacement of the lower fragment, which has been carefully described by Roberts, of Philadelphia. The author does not claim that all fractures of the lower end of the radius are included within one of these classes, as other varieties are possible, but he wishes to call attention to the variety of the conditions found. In conclusion he emphasizes the following points: 1. True Colles' fracture formed by 46 per cent. of 140 cases of fracture of the lower end of the radius. 2. A knowledge of the position of the fragments is necessary for intelligent treatment. 3. The application of padding and splints should vary according to the displacement shown in the skiagram. 4. If the X-ray shows that marked deformity is still present after the splints have been applied, ether should be given, and another energetic attempt at reduction made. 5. Concomitant fracture of the ulnar styloid occurred in at least 62 per cent. of 140 cases, and if 39 cases in which this process was obscure in the skiagram are deducted, fracture occurred in 86 per cent. 6. In true Colles' fracture pressure over the anterior edge of the upper fragment should be avoided and cross-traction should be used to correct the radial displacement of the lower fragment. 7. Statistics of the result of Colles' fracture are not of value unless the pathology of each case is determined by a skiagram.

25. **Traumatic Joints.**—The conclusions of Gage's article are as follows: 1. All injuries to joints accompanied by loss of function are always attended by more or less laceration of the tissues in or about the joint. 2. Delays in the restoration of function are due in most instances, not to any complicating diathesis, but to the changes incident to the repair of these lacerations and their effects. 3. Such delays are best avoided by an early resort to massage and active or passive motions, and are favored by too long a continuance of rest and fixation. 4. When such delays have occurred, they are best overcome by more vigorous and persistent manipulation, supplemented by the application of heat or such other agents as may best stimulate the local circulation and favor the elasticity of the tissues.

26. **Pyosalpinx.**—From a study of thirty cases, Whiteside and Walton conclude that the gonococcus can not be proved to be the cause in so large a number of instances as is generally supposed. Pure cultures are obtained of other organisms, such as bacillus mesentericus, pneumococcus, colon bacillus, streptococcus pyogenes. It can not be proved that the gonococcus pre-existed in these cases and prepared the way, nor can it be disproved by such results as they have obtained. The experiments attempted to demonstrate the possibility of producing pyosalpinx by the pure cultures of these organs were all entirely negative. They do not consider the blood-count of great diagnostic or prognostic importance in this condition, and from a study of several cases they think the majority, when first seen by the surgeon, have had previous attacks. The symptoms are noted in detail and from their series of cases they conclude that the mortality of the operation taken as a whole is 16 per cent. The greatest dangers to be apprehended are in streptococcus infections from peritonitis, in all drained cases from fecal fistula, and in tubercular cases from extension of the disease to other organs.

28. **Diet in the Tropics.**—The question of diet in the tropics is discussed by Owen, who maintains from his results that the average worker in hot climates requires more food than in a cooler temperature. The laborers in the tropics do not live on vegetable food from choice, it is simply because it is more easily obtained and less liable to deterioration. This condition is exactly reversed with the Eskimo, who lives on fats. It is a matter forced upon the races by the circumstances of the surroundings, though custom has given a liking to each for his own diet. He maintains that if there is any change to be made in our diet for the tropics it should be in the nature of an increased allowance. It is not a reduction of the diet that is required, but the food should be handled with more care and be better prepared. He admits, he says, that the body may create less heat in hot climates and that his argument is not quite complete.

38.—This article has appeared elsewhere. See The Journal of August 4, p. 267.

45. **Conservatism in Genito-Urinary Work.**—Charlton notices the over-treatment of many cases of gonorrhea, a disease which is so dangerous in its effects and very common, though he repudiates the statement of Tait that every man has suffered from it. The too active treatment of stricture and the necessity of early conservative operation in kidney disease are also emphasized.

46. **Electricity.**—Static electricity is the special form here mentioned by Lowder, who finds it most beneficial in headache, painful menstruation, insomnia, nervous troubles, etc. He says we can abort an incipient cold, ease pain of an abscess, make more rapid convalescence from fevers, debility, brain fag, bronchitis, etc. Static electricity as used by him is one of the most wonderful therapeutic agents at his command.

48.—See abstract in The Journal, xxxiv, p. 1333.

49.—Ibid.

52. **Ophthalmic History of an English School.**—Stephenson reports the history, as regards contagious eye troubles, of an English charitable institution in London—the Hanwell School. The one great lesson it offers is that trachoma, no matter how prevalent and of how long standing, can be stamped out and that the continuance of such a condition in any institution is a standing reproach to its management, both lay and medical. The special measures taken were the erection of an isolation building and the complete remodeling of the main structures, which hastened and brought to rapid end the disease which had been under strictly medical measures in the old structures with only very gradual lessening.

54. **Coloboma of the Optic Nerve.**—Goerlitz reports the examination of a so-called coloboma of the nerve, which was found to be a case of unilateral malformation of the disc which corresponded to the ophthalmic picture usually given under this name. Macroscopically the enucleated ball showed a small cornea and a dilated intervaginal space. Below the nerve and between the sclera and the sheaths of the nerve there was a small elevation; the optic disc was enlarged in all its diameters and depressed in its lower portion, while its vessels had an anomalous course. Microscopically there was found a defect in the choroid leading into a circumscribed ectasia of the sclera having irregularly thickened walls. In the defect the choroid was wanting entirely, as was also the pigment epithelium. The scleral defect was filled with nerve fibers running from the disc, and a trace of other retinal elements. The optic nerve was fairly normal except for some irregularities and defects of the lamina cribrosa. The intervaginal space was conspicuously distended. The author says, comparing the anatomical condition in this case to previous ones it appears that this malformation is not so much a coloboma of the optic nerve as a coloboma of the choroid and retina with secondary formation of a scleral cyst of the lower margin of the disc.

55. **Distention of the Sheath of the Optic Nerve.**—The case reported by Foster and in which the Kroenlein operation was performed, was one of distention of the sheath of the optic nerve with cerebrospinal fluid, a condition which has rarely, if ever, been described. The author discusses the condition and notes especially the absence of optic neuritis, showing that the collection of fluid in the sheath of the optic nerve, even when it is very large, does not necessarily produce this condition.

57. **The Theory of Accommodation.**—Suter defends the Helmholtz theory of accommodation as opposed to that of Tscherning, and reports experiments made by him on the eye which seem to favor his view.

58. **Evisceration of the Eye-Ball.**—What is called simple evisceration is really, as Gifford says, evisceration plus keratectomy. For two years past he has been doing an operation which is a strictly simple evisceration; instead of cutting out the cornea he has made a meridianal incision entirely within the sclera or extending partly or entirely across the cornea, and has completed the operation through the opening thus made without removing any of the cornea. The results have convinced him that this should be the operation of election. The simple evisceration he claims tends to avoid the bursting open of the wound, first, by permitting the incision, which can be better coapted than where keratectomy is done, and second, and most important, it leaves so much more space within the globe that there is more time for the scar to organize before the contraction of the sclera attempts to stretch it over the artificial vitreous.

65.—See abstract in The Journal, xxxiv, p. 1338.

66. **Membranous Dysmenorrhea.**—From a study of the literature of several cases reported, De Wit concludes that the theory which seems to her most consistent with the histologic findings in the reported cases, as well as in those examined by herself, since inflammation is not a uniformly accompanying condition, and conception may often be positively excluded, is that perhaps under some abnormal local nerve influence, which may be congenital—since in many cases the disease begins at puberty—or even as suggested by Gautier, hereditary, or which may, through injury or local disease, be later acquired, the normal menstrual congestion and blood extravasation or fluid exudation is so greatly increased that the deeper tissues break and thus loosen the thickened decidua menstrualis *en masse* before nutrition has been sufficiently interfered with to cause its degeneration.

70. **Suspension of the Uterus on the Round Ligaments.**—Beck describes the operation previously published by him in the *Centralblatt fur Chirurgie* in 1897. The main features of this method consist in opening the abdomen in the linea alba by a small incision, seizing the fundus uteri with a traction forceps and pulling it outside the abdominal cavity. This procedure is facilitated by Trendelenburg's position. The round ligament of one side is then selected and freed to the extent of nearly three inches, the isolation beginning near its uterine attachment. Superficial incisions along both sides of the ligament permit the introduction of a grooved director.

by means of which the peritoneum can be stripped away bluntly, so that no hemorrhage occurs. The bared ligament is then held up by an aneurysm needle and pulled out from the abdomen to such an extent that the peritoneal wound margins can be united underneath. Six to seven catgut sutures suffice for the purpose. The ligament now rides on the peritoneum. To strengthen this peritoneal anchorage, fascia and muscle are also united underneath, while the ligament is suspended like a loop of a coat on a broad hook. One additional suture through the ligament itself usually suffices for fastening the ligament to the suture row. The remaining portion of the wound is dealt with in the usual manner. The margins of the integument are brought together by subcutaneous catgut sutures. Two relaxation sutures, consisting of iodoform silk, are applied through the skin, three-quarters of an inch distant from the wound margin, so that there is no direct contact with the wound-line. For prolapsus uteri the suspension of one ligament alone is sufficient, though a lateral position can not be avoided, but is usually harmless. In retroversion, fixation of both ligaments is, of course, necessary. From his experience of four years he claims that the only disadvantage of this operation and its modification is that it requires an opening of the peritoneum, but it has the great advantage of suspending the uterus in a perfectly normal position, which permits of such free motion that there is no interference either with the bladder or the rectum and no obstacle to pregnancy, as is usually the case with the ventrofixation methods.

74. **Cancer of Cervix and Fibromyomata of Uterus.**—The "rare conditions" described by Weir are primary cancer of the cervix uteri in a nulliparous woman, and fibromyomata of the uterus associated with fibroid of the right ovary.

78.—This article has appeared in various journals and was abstracted in The Journal, xxxiii, p. 977.

84. **Fracture of the Femur.**—Davis describes the method of uniting a fracture of the neck of the femur by a straight incision down from the anterior superior spine of the ilium, being careful not to go so far down as to endanger any large blood-vessels or nerves, opening up between the capsule of the joint on its anterior surface between the two arms of the Y-ligaments and permitting the free entrance of the index finger and the use of instruments. This opening need not be closed before using the ivory pins to hold the fragments after getting them into position, leaving the pins in place. He thinks a still more efficient way would be to use a silver-plated screw. Two cases are reported; in the first he used steel pins, in the second, ivory pins were used with good results.

95. **Practical Hygiene.**—The subjects of tuberculosis, scarlet fever and typhoid fever form the chief theme of Hopkins' article. As regards tuberculosis, he maintains that Koch's discovery of its germ has been the most "hopeful gospel" to mankind for 1800 years, and he reiterates the usual instructions in regard to its prophylaxis. As regards typhoid fever, he says that this has become in New York state a rural disease due to insanitary conditions in the country districts, and calls attention to the necessity of better attention to sanitary conditions of the farms as well as to the farm products that come from them, which may carry the infection. As regards scarlet fever, he maintains that its infection is slight in the beginning, but becomes intense during the desquamative period and points out how, especially in country homes, isolation in this period should be secured.

96. **Nitrous Oxid Gas and Ether.**—Le Breton describes the Hewitt inhaler and Bennett modification and the Goldan apparatus, which has the advantages of simplicity and comparative cheapness. He calls attention to the practical points of rapidity in the transition from gas to ether and the necessity of not continuing the gas administration too long. The advantages are, comfort to the patient; freedom from excess of mucus and saliva; the smaller quantity of ether employed; the less liability of kidney complications on this account; the comparative cheapness of the combined method; the greater ease with which certain cases, alcoholics, especially, are anesthetized; the time saved, and the safety. The chief disadvantage is the cost and the bulkiness of the apparatus.

98. **Abuse of Quinin.**—The overusage of quinin by the laity is here deprecated by Church. He thinks the drug is given too much and it would be better if the laity knew less about it, as well as about morphin and some other drugs. He reviews the testimony as to the physiologic effect of quinin and names some of the evil consequences that sometimes have followed its use, such as blindness, headache, nervousness, etc. He says that quinin is contraindicated in inflammation of the middle ear and labyrinth, in renal irritation, in acute inflammation of the gastrointestinal tract and in still other cases it is not well borne.

99. **Nursing-Bottles.**—Wende's article points out the dangers of long-tube nursing-bottles and illustrates them by microscopic pictures showing the possibilities of infection by these long tubes.

102. **The Venom of Snakes.**—McFarland mentions the different kinds of venomous snakes inhabiting the United States, which are rattlesnakes, about twelve species, the moccasin and copperhead and the coral snake of the South. He describes the mechanism of their poisoning apparatus and the different effects of the poisons of different species. Usually the size of the animal has much to do with the seriousness of the injury, that by the copperhead and little ground rattler seldom producing general poisoning, though the local effects are usually marked. The various remedies are mentioned, especially antivenene, and in conclusion he says that, briefly outlined, the treatment of snake-bite is: 1. Immediate interruption of the circulation of the bitten member, so as to prevent absorption of the poison. 2. Free incision and enlargement of the fang-wound and forcible suction to extract the poison. 3. Hypodermic injection of three to six drops of a fresh water 10 per cent. solution of chlorid of calcium in about a dozen different areas about the wound. 4. Strychnia given hypodermically to stimulate the respiratory center. 5. Immediate and frequent repeated hypodermic injections of ten to 20 cubic centimeters of the antivenomous serum, or as Calmette calls it, "antivenene." The most urgent need of the patient is for immediate, unlimited administration of antivenene. It would be a wise precaution for persons who are in continual danger of snake-bites to provide themselves with this remedy and carry it with them.

103. **State Medical Examinations.**—The difficulties in the way of uniform state medical examinations and the common standard are noticed and Lewis mentions the objections to the present rules. He believes that it would be perhaps possible to secure reciprocity if the District of Columbia standard were generally adopted to meet all the conditions. Should the National Board of Health movement now under contemplation be successful, it might be best to utilize that body for this purpose.

113. **Gelatin Injections in Aneurysm.**—Four cases of aneurysm treated with gelatin injections are described by Nietert, and the conclusions drawn therefrom are stated as follows: 1. Great pain at site of injection often follows introduction of a large amount of the fluid. 2. The gelatin being a good medium for the development of micro-organisms, great care is required to keep it sterile. 3. The symptomatology is greatly improved in every case; the pain is usually lessened, the patient breathes easier and shows less pressure symptoms on important surrounding organs. 4. In most cases the tumor becomes more firm and expansibility less marked. 5. It is likely that great good can be effected by the gelatin injected in aneurysm of the smaller vessels. 6. Post-mortem examination in every case shows large organized clots, filling the cavity of the aneurysm, which are undoubtedly due in a great measure to the gelatin.

118.—This article has appeared elsewhere. See abstract in The Journal of July 29, ¶26, p. 257.

120. **Reflex Pelvic Neuroses.**—Robison details the elaborate nervous supply of the genital organs, describing the cervicouterine ganglion as the pelvic brain, giving its connections, and calling attention to the gastric, cardiac and other reflexes produced by the irritation of these parts.

123. **Convergent Strabismus.**—Bane emphasizes the importance of examining the eye at the earliest possible moment on the appearance of strabismus and the correction of any errors of refraction with spectacles, even if the child be but 2 years old; also the use of the occlusion pad in all suitable cases. Operation is advised as soon as there is positive evidence that further gain can not be made by the educative treatment.

127.—Ibid., p. 577.

128.—Ibid.

129.—Ibid.

130.—Ibid., p. 578.

131.—Ibid., p. 577.

133.—Ibid., August 18, p. 447.

136.—**Digestion of Breads.**—The questions as to the dryness or moistness of bread eaten and the sterility from baking are discussed by Perry. He finds that there is no reason for ascribing gastric disorders to the presence of living bacteria, for the heat of baking in loaves of less than 2 pounds weight is enough (203 F.) to kill all gastric fermentation bacteria that may have been in the materials used. Those found in the London examination of Walsh were other innocent species and were found only in 4-pound loaves. The dryness of the bread with porosity, on which depends the amount of saliva which is absorbed in chewing is the main factor in determining the digestibility of the bread. If bread which is dry and porous is soaked in liquids before eating, or in the mouth while eating, its character of easy digestibility is taken away.

139. **Ergot.**—The physiologic action of ergot, as Seymour says, is to stimulate the vasomotor nerve-centers. Its action upon unstriped muscular fibers produces contraction of the blood-vessels and with the single exception of uterine hemorrhage, the arrest of non-traumatic bleeding is best effected by the induction of vasomotor paresis. The use of vasomotor excitants might be rational only if their action could be restricted to the immediate territory involved. We have been misled by taking uterine hemorrhage as the type of all hemorrhages in these cases. He has seen ergot produce a persistent diarrhea due to its action, undoubtedly, on the peristaltic muscles, yet it is often given for the control of intestinal hemorrhage. A protective clot stands a poor chance of adhesions under its grip. Its use in the cerebral or pulmonary bleedings is still more perilous. The blood-pressure within the cranium may be disastrously intensified and in pulmonary hemorrhage the increased vasomotor tension exaggerates the condition.

146.—**Pyorrhea Alveolaris.**—The relation of Riggs' disease to general surgery is here noticed by Abbott, who believes that it is responsible for many conditions, such as putrid exudates, etc. He mentions a case where this has developed extensive inflammation and septic infiltration of the lymphatics and glands of the floor of the mouth, the throat and the neck. In other cases it may produce antral disease, and he has heard of a case of cystitis which cleared up at once after the extraction of the diseased tooth. He asks what surgeon would allow his patient to take five or six drops of pus three or four times a day, yet this must be the case with sufferers from this disorder.

151. **Electric Light and the Eye.**—Roy reports a number of cases of irritation of the eye from the use of electric light, both arc and incandescent. The chief points of interest are whether the dangers produced are of chemical or traumatic origin, the presence of contraction of the pupils from retinal irritation persisting for days, and pain occurring several hours after the accident.

160. **Commercialism in Medicine.**—Armstrong gives his views as to the pervading spirit of commercialism as he sees it, and especially the need of modification of the Texas medical laws. He writes forcibly and as far as medicine is concerned, leaving out the politics and poetry, which may not agree with everybody, his views deserve general acceptation.

FOREIGN.

British Medical Journal, September 22.

A Discussion on the Correlation Between Sexual Function, Insanity and Crime.—The chief paper in this discussion is furnished by H. Macnaughton-Jones, the distinguished gynecologist, whose conclusions are given as follows: 1. Functional disorders of ovulation are frequently attended by mental aberration, and in a proportion of cases originate the mental disturbance. The same remark applies to disorders of ovulation which have a pathological cause. 2. In the great majority of such cases, the nervous disturbance is of the neurasthenic character, and is associated with various visceral or other neuroses. In only a small proportion does the alienation assume so grave a type as melancholia, mania, or dementia. 3. Where in an insane person, ovulation and its external manifestation, the menstrual discharge, are erratic or absent, the erraticism or absence may be a consequence of the general and insane condition, and not a causal factor in its production; but under any circumstances such abnormal menstruation appears to have an aggravating effect on the insanity, and there is sufficient evidence to support the view that when such irregularity—especially if it be due to a pathological cause—exists, it should be treated therapeutically or by operative measures. 4. The question of a gynecological examination of an insane woman must be a matter for the discretion of the psychologist, influenced by the gynecological view as to its expediency from the signs and symptoms present in the sexual organs. For many reasons, as a universal practice, with our present knowledge it is not advisable. 5. Sufficient evidence is now advanced to justify the removal of the adnexa or uterus in insane women, when there are gross lesions of the former or tumors of the latter. Here, again, such operation must be advised according to the psychological condition of the patient and the type of her insanity. 6. From a mass of evidence, including some of the largest experiences in Europe, Canada, and America, it does not appear that there is in healthfully-minded women, who suffer from diseases of the genitalia, any special risk of post-operative insanity. On the other hand, if there be a psychopathic predisposition, which had existed prior to and independently of the sexual disease, there is in such cases a larger percentage of post-operative mental disturbance than follows other operations. In such women the prudence of a radical operation may have to be carefully discussed. The post-operative mental effect does not appear generally to be of a serious or permanent nature. 7. It may be generally affirmed that when mental disease of a graver type follows upon sexual disorder there has been in the woman affected an underlying and often unrecognized psychopathic predisposition; the disorder of the menstruation or the disease in the genitalia completing the chain of the vicious circle needful for the final manifestation of the mental condition. 8. The relation of aberrant sexual function or a disorder of menstruation to any criminal act ought to be taken into consideration in determining the responsibility of the women.

Acute Delirious Mania. John Turner.—Turner recognizes three divisions of acute delirious mania: 1. Those of alcoholic origin. 2. Those of septic origin. 3. Those in which we are not able at present to identify any particular poison as the cause. It is the latter form that the author chiefly treats of in this article. The main point to which he calls attention is that the most of these cases present definite alterations of certain of the cortical nerve cells—chiefly the giant cells of Betz—so much so that they are almost characteristic. He says *almost*, because in at least once case he was not able to find this change though other cells showed pronounced changes. He remarks on the symptoms, reports cases, and figures the changes that he has observed. The naked-eye appearances consist chiefly in intensely congested areas in the meninges and sometimes thrombosis and hemorrhage. From his study he believes that all forms of acute delirious mania are of toxic origin, but while some are obviously caused by the introduction of poison from without or the absorption of certain matters there is a third class due to auto-intoxication, probably from perverted metabolism which is probably caused by a disordered nervous system. In these acute cases occurring in the prime of life we almost always meet with fatty degeneration of the liver, an organ one of whose functions is probably to prevent the introduction into the system of poisonous intestinal products. It may be asked why some nerve-cells suffer while others in their neighborhood escape. It may be, he says, that these particular cells, which are chiefly concerned in the production of the symptoms are those which will feel the chief effect of the poison. If, as some hold, accumulation of pigment in the nerve-cells is an expression of past and probably recent activity, the fact that the cells which are most pigmented are usually those most affected will bear out this contention. The subject is, however, as yet too speculative for beneficial discussion. The cells just described are found here and there in many other forms of insanity with different clinical histories and even in some cases of acute delirious mania only a minor proportion of the giant cells are markedly affected. As a rule, however, in cases with high delirium and a rapidly fatal termination we generally meet with a condition in which all the giant cells are profoundly altered and the author believes from an inspection of such a section a diagnosis can be formed of the mental condition preceding death.

Organo-Therapeutics in Mental Diseases. C. C. Easterbrook.—The origin of organo-therapeutics dates from Brown-Séquard's experiments in 1889 and the doctrine of internal secretion formulated by him that "all glands and all tissues have an internal secretion and all injected subcutaneously have a tonic effect" is taken as the text of this article. During the past five or six years Easterbrook has administered in various forms of insanity extracts of the following animal organs: The thyroid gland, the parathyroid bodies, the thymus, the pituitary body, the brain, the choroid plexus, the spleen, the suprarenal bodies, the testes, the ovaries, the uterus, and the mammæ. With the exception of the thyroid, none of these have been very generally employed by alienists, and parathyroid extract so far as he knows has not been employed before at all. He carefully selected his cases among patients not progressing toward recovery under other treatment, and sought to avoid the fallacies of calling temporary remissions recoveries, or to attribute to the drug any improvement or change that might be due naturally to the course of the disease and he has also excluded all psycho-therapeutic influences in any form so far as possible. His patients were first weighed and put to bed on a diet sufficient to maintain the body temperature and body weight, careful notes made of the state of the bodily and mental functions, the excretions, the blood, urine, etc., with careful quantitive and qualitative examinations and microscopic studies. Sphygmographic tracings, and observations of the blood-pressure with sphygmometer were also made in some cases. In the 130 cases tested with the thyroid extract, including a large number of forms of insanity and almost the whole range of symptoms of the disease, large and small doses were given separately and effects noted as producing changes in the temperature, circulation, nervous system, urine, etc. Small and moderate doses were tolerated well by all. Large doses were badly borne by those under 20 and over 60 years. Easterbrook suggests that, in the old, the thyroid gland is feebly functional and the system is not prepared for much thyroid secretion, while in the young it is freely active and the system well supplied, therefore any addition is superfluous. In the 130 cases there are 12 recoveries which he thinks can be attributed to the drug and 29 cases were improved. All the recovered cases had been selected as failures from former treatment, the average duration of treatment before thyroid medication having been eight months. Several cases that had been treated, recovered some time after, which indicates that a patient not cured by the thyroid method may still recover by other means. Nevertheless his experience is that if the patient is going to recover under this drug it will be done with the first few large doses. When used in chronic insanity temporary improvement is common and he has found it useful in aborting periodic attacks of violence. The therapeutic effects of parathyroid were negative, the same is true as regards mental symptoms with thymus and pituitary extracts, though there was in some cases temporary improvement with both. Brain extract was used in 19 cases, of which 2 recovered and 3 were improved. Choroid plexus extract was negative in its results. Suprarenal extract he thinks had some effect in increasing the blood-pressure and he would advise a systematic trial in maniacal cases. It seems also to produce a specific diminution of tissue oxidation. With the splenic extract there was in two cases temporary improvement physically and mentally with subsequent relapse. Of the 8 cases treated with orchitic extract 3 were improved mentally while 2 others were physically benefited. Thirty-six cases were treated with the ovarian extract, 2 of the patients recovered long after the treatment, probably independently of it and 4 cases, mainly stuporous, were improved. Two of the patients in whom the ovaries had been extracted or destroyed by disease were unimproved either mentally and physically by large doses. Uterine extract was negative. The 2 cases treated by the mammary extract were affected with a rise in temperature and loss in weight, but no change in other respects; both however fully recovered, one after a careful thyroid treatment. In conclusion, he states that Brown-Séquard's generalization needs some modification. His own investigation led him to conclude that those animal extracts which consist mainly of simple proteids and albuminoids have merely a dietetic value, but those that are rich in nucleins and nuclein proteids produce when given in sufficient doses a temporary stimulation of cell katabolism and subsequent anabolic reaction. It is important to recognize this tonic effect. Apart from this it is extremely doubtful whether each organ possesses a specific internal secretion in the sense intended by Brown-Séquard. Some organs, however, as the thyroid with its iodothyrin and the suprarenal bodies with their active principle have a decided special effect. Thyroid extract stands far and above all others in stimulating tissue oxidation, and anabolic reaction never sets in until after the cessation of the drug, which is not the case with other extracts.

Revue de Medicine (Paris), July and August.

Affections of the Spinal Cord in Heredo-Syphilitic Infants. De Peters.—In certain cases symptoms indicating an affection of the spinal cord are the only means of diagnosing inherited syphilis. De Peters has observed eleven such instances. Nothing suggested syphilis in either parents or children except the nervous symptoms and the fact that they yielded promptly to specific treatment. In some cases there was isolated paralysis of the muscles of the scapular region, isolated paresis of the leg, isolated contraction of a group of muscles, as, for example, the psoas and iliac muscles, or those of the back of the neck, coexisting with paralysis of other muscles, or the oculo-pupilary Dejérine-Klumpke symptom alone. In differentiating this from obstetrical paralysis, an important point is that the latter is more apt to occur in well-developed children born at term and that it is usually unilateral.

Acute Dysenteric Hepatitis. P. Remlinger.—The acute non-suppurative hepatitis accompanying dysentery commences during or consecutive to the latter—eighteen months after in one of the four cases described, and nine years in another, after the first manifestations of the recurring dysentery. The onset is sudden and violent. Morphin is powerless to relieve the intense pain. The liver appears hypertrophied all over, the spleen normal. Ordinary treatment is ineffectual, but local blood-letting is followed by almost immediate relief.

August.

Gastrointestinal Troubles from Nervousness. Dubois.—No organ is so sensitive to the emotions as the gastrointestinal canal. It is the mirror of the condition of our soul, Dubois asserts. Pavloff showed that a dog secreted as much gastric juice at the sight of his dinner on a dish as another dog given 100 gm. of meat. This demonstration of a "psychic appetite" has been supplemented by Kronecker's recent experiments proving the effect of fear on peristalsis. The influence of massage and exercise was evidenced in the passage of a silver ball through the isolated intestine of a dog by increased peristalsis. A threatened beating, however, sent the ball along more rapidly than all the physical measures combined. A number of typical cases of nervous gastrointestinal affections are described in this communication and the benefits to be derived from measures to educate the will, control the reason and train the intestines, combat the nervous preoccupation and divert the patient's attention, are emphasized. Medication is useless in these cases.

Berliner Klinische Wochenschrift, August 27, September 3 and 10.

Peculiar Dangers of Otitis in Elderly People. Heine.—With advancing years osteosclerosis of the mastoid process frequently occurs, but is usually confined to the external portion, while the internal portion of the temporal bone retains its spongy character. For this reason suppurative processes do not readily work outward, while serious lesions may be progressing in the depths. Four instructive cases are described, forcing the conclusion that patients over 40 with inflammation of the middle ear should be operated on as promptly as possible, otherwise rapidly fatal cerebral complications are liable to supervene.

Adjustable Spectacle Frame. L. Sarason.—To prevent myopic school-children from using distance glasses for near work, the lenses are suspended in the frame from the top. They consequently swing outward out of the line of vision whenever the head is bent forward.

September 3.

Injuries from Lime in the Eye. Schmidt-Rimpler.—A 100-gm. syringe and a bottle of oil should be kept where lime is being used. In case of an injury to the eye from the lime the oil should be injected from the external angle and the eye well irrigated with it.

September 10.

Harmful Suggestion in Accident Cases. W. Seiffer.—The writer of this communication is assistant at the Nerven-Klinik of the Berlin Charité, and describes from his personal experience the vast harm done by physicians in expressing an unfavorable prognosis on the first examination of a patient after an accident. He attaches the utmost importance to the physician's verdict at such times and requires a tonic, psychic treatment, suggestion of rapid recovery, while a grave prognosis announced is liable to increase the gravity of the traumatism. His cases of more or less conscious simulation, traumatic hypochondria and hysterical paralysis, lead him to endorse Bruns' statement that traumatic nervous affections are due far more to subsequent events and emotions than to the trauma itself. He therefore begs physicians to weigh their words well at such times and to err, if they err at all, on the side of a too favorable prognosis.

How to Secure Asepsis in Catheterization of Ureters. M. Katzenstein.—Tests at Israel's surgical clinic have conclusively demonstrated that it is impossible to sterilize catheters thoroughly with sublimate, while other processes are liable to injure the catheters, and disinfection with formaldehyde has been tedious and insufficient hitherto. Katzenstein has constructed an improved apparatus which consists of a tall metal box 17 cm. long, 11 cm. high and only 2.5 cm. deep, on the floor of which tri-oxy-methylen—which is nothing but polymerized formaldehyde—is scattered. The back of the box is pierced with a dozen small openings containing each a small tube, terminating on the outside with a screw-thread on which a cap or a catheter is screwed. An oblong metal box of the same width and height, but 44 cm. long, fits on the gas chamber above-described and supports the catheters on a wire tray. The gas generated in the small chamber has no means of escape except through the catheters screwed on the tubes opening into it, which are thus rendered sterile in ten minutes. Ureteral catheters only require twenty minutes at most. The large box is made in two halves that telescope, so that it can be drawn out to a length of 80 cm. The heat is supplied by three small gas jets, raising the temperature to 60 or 80 C. in the generating chamber. Catheters are not injured by this process. A small pocket apparatus is made on the same principle, the heat supplied by a thermophore attachment.

Success of Chirol "Varnish Gloves." R. Kossmann.—The hands are first thoroughly sterilized and then dipped for fifteen seconds—no longer—in the fluid chirol. They dry in three minutes and neither sweat nor germs can pass through these varnished gloves from within nor germs nor fluids from without. Kossmann describes a number of tests in which the fingers were rubbed on cultures of bacillus pyocyaneus and prodigiosus and then pressed and rubbed three times on a plate of agar. They were then dipped in the chirol without sterilization and pressed again on the agar a number of times. Not a single culture developed after the chirol had been applied while numerous colonies grew at each one of the three points first touched. Even without preliminary sterilization, the value of chirol in preventing infection promises to be inestimable, because it plugs up all the crevices and nail-spaces.

Deutsche Medicinische Wochenschrift (Leipsic), September 22.

The Neuron in Anatomy and Physiology. M. Verworn.—This summary of the facts on which the neuron theory is founded was presented at the Congress of Physicians and Naturalists which met at Aix-la-Chapelle, September 19. Nissl believes that the theory of the neuron as a unit is untenable, but Verworn claims that all the latest researches have merely confirmed this theory. He admits that the neuron is not the same thing everywhere that we see in Golgi's pictures of the cells of the anterior cornua. The neuron is of many varieties and shapes, according to its location and its function, as Nature never works by an exact pattern. Modern research has led to the further and freer evolution of the conception of the neuron as a cellular unit. He reports experiments which show that the metabolism in the central nerve-centers is incomparably more intense than in the peripheral nerves, also that the centers pass through stages of fatigue and exhaustion the same as the muscles; fatigue from autointoxication and exhaustion from using up the reserve supplies, especially of oxygen. His pupil, Baglioni, is soon to publish an account of researches which show that strychnin injected into the spinal cord affects exclusively the sensory elements of the posterior horns, increasing their excitability to an enormous degree, while carbolic acid in certain solutions affects merely the motor elements of the anterior horns, increasing their excitability.

Reposition of Luxated Shoulder by Riedel's Method. Graef.—It is amazing, Graef observes, after years of experience with the old and frequently unreliable method of traction by four men on the upstretched arm, to see the ease and rapidity with which a severe anterior luxation of the shoulder can be reduced by Riedel's method. Narcosis is indispensable. The muscles prevent the entrance of the head into its socket, but once relaxed by complete narcosis, the head is held only by the tendon connecting the acromion and the middle portion of the humerus. If the arm in extreme adduction is then pulled from below diagonally across the body toward the sound side of the pelvis, the head slips easily and immediately into place.

Another Toe-Finger. Eiselsberg.—The right forefinger of a young man had been cut off four months before the operation described. Eiselsberg applied in its place the second toe, leaving it still attached to the foot by a portion of the soft parts, and applying a plaster cast. The connecting bridge was gradually severed and completely divided by the twelfth day. None of the toe was lost and sensibility has developed; mobility has not yet appeared, but is confidently expected in time, as occurred in Nicoladoni's toe-finger operation two years ago.

Acute Progressive Peritonitis Cured by Operation. Urban.—Two children 3 and 3½ years old, respectively, with severe progressive peritonitis, one apparently moribund, were treated by incising the abdomen on the median line for 6 to 8 cm., nine and four days after commencement of the disease. The wound was not irrigated nor drained but was left open and dry dressings were applied. Improvement commenced at once, and went on to recovery.

Mittheilungen a. d. Grenzgebieten der Med. u. Chir. (Jena), vi, 4 and 5.

Experimental Production of Gall-Stones. H. Miyake.—Introducing foreign bodies or cauterizing the mucosa, etc., never led to the production of a true calculus in [illegible] experimental research reported. Infection proved [illegible] ind[illegible]pensable factor, with the consecutive [illegible] biliary passages, combined with means to prevent expulsion of the stones.

Omentum Tumors. R. BORRMANN.—In studying the published descriptions of "omentum tumors" the statement is always found that a portion of the tumor was adherent at some point to the stomach or colon. Borrmann claims that the tumor originally developed from the organ to which it is adherent and grew between the layers of the omentum.

Technique of Esophagoscopy. G. GOTTSTEIN.—According to the technique employed at Mikulicz' clinic the patient reclines on his right side on a table, the head slightly drawn back, the physician seated on a low chair at his head. The tongue and entrance to the esophagus are swabbed with a 10 per cent. solution of cocain. Once past the entrance, the esophagus offers no further obstacle to the passage of the tube, but it may require considerable gentle manipulations to enter it. A Casper panelectroscope is then applied. Esophagoscopy is no more dangerous than any other procedure of the kind.

Muenchener Medicinische Wochenschrift, September 18

Gout in Germany. A. STRUEMPELL.—The Germans have always claimed that gout was rare in their country, but Struempell states that it is frequently encountered now and that the failure to note it before was due to the lack of search for it. The majority of patients he has observed were connected with the manufacture or sale of beer, or had been exposed to lead-poisoning.

Inflammation of the Gall-Bladder and Consecutive Gastrointestinal Disturbances. W. FLEINER.—The writer recommends flushing the stomach with tepid water and rectal injections of oil as effective means of combating the gastrointestinal disturbances left after an acute cholecystitis. The oil actively promotes peristalsis and proves a powerful cholagogue. Irrigating the fasting stomach rinses out the whole organism, especially the liver, as a portion of the water is absorbed by the portal vein and carried directly to the liver. He extols these systematic flushings of the stomach as fully equal to a course at Carlsbad, and even more effective in certain cases, while they can be carried out at any time and are not restricted to the watering-place season. They exert a gymnastic influence on the gall-bladder as well, preventing the formation of adhesions between it and the stomach, and thus curing many a case of motor insufficiency of the stomach from this cause. A tendency to hemorrhage on the part of the gastric mucosa is a counterindication for lavage.

Acute Lukemia. A. DENNING.—A case is described in which an otherwise typical lymphatic leukemia or lymphemia was not accompanied by any perceptible alteration or swelling of the glands, and the spleen and liver did not become hypertrophied until the last stages of the disease. The condition of the gums and mouth suggested scorbutus. This emphasizes the necessity of examination of the blood in every case of stomatitis of unknown origin.

Gas Gangrene. G. MUSCATELLO.—Five cases are described of local gangrene with gas formation and symptoms of general intoxication, only differing by the complication with inflammatory processes which was observed in a few, and by a tendency to the invasion of the surrounding sound tissue in connection with the inflammatory processes. The bacillus aerogenes capsulatus was found in three cases. It evidently has no action on sound, but primarily invades altered tissues. The bacillus coli communis was found associated with the proteus in one, and with the streptococcus in another case. All the patients recovered, three after amputation of the arm, leg or thigh in which the infection had developed after a traumatism—stab wound or compound fracture. In another case the gangrene developed consecutive to abdominal extraperitoneal nephrectomy. The wound apparently healed but required reopening on account of swelling and fluctuation. The walls of the cavity were found brown and soft, with gas bubbles in them and in the adjacent lumbar muscles. Energetic disinfection with potassium permanganate and iodin arrested the gangrene and the patient recovered. It appeared in another patient after removal of an arterio-venous aneurysm in the popliteal space requiring ligature of the artery above and below. The gangrene also invaded the stump two days after amputation, but was cured by reopening the wound and vigorous disinfection and medicinal measures every four hours. The popliteal vein in the amputated limb was found obstructed with a thrombus at the point of the lower ligature. The gangrene extended to the point of the upper ligature, where it ended abruptly in the midst of sound tissue. The bacillus aerogenes was found pure in the two last cases.

Therapie der Gegenwart (Berlin), July and August.

Lumbar Puncture in Children. O. KOHTS—Temporary improvement was observed in several cases of tubercular meningitis, but Kohts' personal experience confirms the danger of procedure in case of cerebral tumor or pronounced spina bifid His experience with it in cerebrospinal meningitis was decidedly favorable. Four have survived out of the seven cases i which lumbar puncture was applied, including two who recovered completely and one who was left somewhat deaf. Nett has also reported five recoveries out of six.

Cinnamic Acid and Leucocytosis in Tuberculosis. C KRAEMER.—Ten clinicians have published their experi with cinnamic acid in the treatment of tuberculosis. Th general verdict on the total of 186 patients is favorable to th remedy, and experimental research has established that action is due to the leucocytosis which it induces. The l cocytes wall off the tubercle and in time lead to its transformation or encapsulation. Other substances induce leucocyt but none combines such purity, solubility and non-toxicity wi such efficiency in even the smallest amounts.

Origin of Catarrhal Conditions of the Respiratory Pa sages. ADLER.—The theory proposed to explain hay and the non-infectious catarrhs of spring and fall, and of elderly people during the winter, assumes that the m lining of the upper air-passages has a different coat for mer and winter. Abrupt transition of the seasons causes t coat to be thrown off rapidly and a catarrhal condition r sults. Some persons are incapable of forming a suitable ep thelial coat for winter weather. In others the summer is defective and the light, odors and floating particles of du and pollen irritate the membrane, culminating in hay-feve All these conditions are based on insufficiency of the epitheli and preventive treatment should be formulated accordingly.

August.

Treatment of Sciatica with External Application Hydrochloric Acid. ELJASZ-RADZIKOWSKI. Twelve cases very severe and rebellious neuralgia, some of neuritic some of scoliotic origin, were all cured by painting the pa ful region with 20 gm. of pure hydrochloric acid at a time, four to eleven applications. In one of the cases the pati was so much improved by one application that he did not turn for further treatment. As the acid penetrates into tissues it is transformed into a harmless chlorid.

Treatment of Pulmonary Tuberculosis with Igazol. CERVELLO.—Fifty-five patients have been treated with ig since its invention fifteen months ago and 15 are now completel cured—appetite, strength, color and weight restored to norm These include 5 in the first stages, 1 quite severely affected, severely affected, and 2 very severely affected. T temperature had varied from 37.5 to 38.5 C. in 6 and 3 between 38.9 and 39.5. Fourteen are nearly cured, includi 6 severely and 2 very severely affected. The temperature in was 35.5 to 38.5, and in 3 was 39 to 40. Ten of the wh number were slightly improved; 5 grew worse; 1 stationary and 10 have died. Even in incurable cases th is always a pause or temporary improvement in the dis The fever vanishes in ten to sixty-four days; the effect on sputa is evident almost from the first. The appetite and g eral health also rapidly improve. (See THE JOURNAL p. 1438.

Wiener Medicinische Wochenschrift, August 25

Treatment of Ulcers with Superheated Air. K. U MANN.—The heated air is brought from a lamp on the fl through a tube into a large, bulging air-chamber with a comparatively small opening at the farther end, which fits close against the region of the ulcer, and is fastened with straps around the trunk. Most of the 50 cases Ullmann has treated in this way were old venereal ulcerations. In 19 cases of chancre the lesion was cured in four to five sittings together with phimosis when it existed. The most brilliant results were obtained in cases of phagedenic ulcerative processes of specific or non-specific nature. In two severe cases, the lesion on the glans penis had resisted all treatment for a year, but rapidly yielded to the dry, hot air. Its action was truly wonderful, Ullmann exclaims, on extensive and hard primary lesions or gummata. The only failure was one fistulous process in the scrotum, which was not improved.

Archivio di Psichiatria (Turin), xxi, 3.

The Hair in Degenerates. L. Battistelli.—Examination of 1000 subjects showed the great preponderance of the low and circular growth of the hair on the forehead, in degenerates, the aberrations and plurality of the vertices, the greater intensity and frequency of the atavistic erection of the hair under the influence of fright, and its greater resistance and vitality.

The Potential of Criminality. R. de la Grasserie.—A normal person may commit a crime by exceeding the limits of legitimate self-defense; there is criminality but no criminal. The born criminal may not have committed a crime; there is the criminal but no criminality. Between these two extremes are the persons who commit crimes from example, or on account of depraved environment. The first group should not be punished at all, except for the effect on the gallery. The second group is incorrigible and a permanent peril to society, against which all means of defense are justifiable. The third class is susceptible of improvement and a return to normal with new and elevating surroundings. Repetition of the specific crime and study of previous arrests are the chief means of detecting the born criminal, supplemented by anatomic and physiologic investigation, including his heredity.

Gaceta Medica (Mexico), September 15.

Retractor for Soft Parts in Amputations. J. Vertiz.—Two thin metal plates cut out in the shape of a very long and broad U are superposed, the ends reversed. The under plate has the edges turned up to form grooves in which the upper one slides into place, when the plates are applied to enclose the bone in the round hole left in the center between the concave portions of the superposed U-plates. The retractor is operated by a strip of gauze passed through a slit at each end.

Semana Medica (Buenos Ayres), August 23.

Subarachnoid Injections of Cocain. B. Podesta.—Grave operations on twenty-one patients were performed with anesthesia from intraspinal cocainization according to Tuffier's directions, injecting from 15 to 20 mg. of cocain in a 2 per cent. solution. There was slight headache for the following twelve to thirty-six hours in only five. None of the others experienced inconveniences of any importance. There was no nausea in any instance. Some of the patients had cardiac or pulmonary affections. All but one were men between 17 and 49. Ten of the operations were for inguinal hernia. The remainder included a vaginal hysterectomy, two laparotomies, stretching the sciatic nerve, removal of hydatid cyst of the liver, a tenotomy, costotomy for a purulent hemothorax consecutive to a stab wound of the lung, etc.

Change of Address.

C Bell, Washington, to 418 South Broad St., Philadelphia, Pa.
B. B. Brashear, Concord, to South Lancaster, Mass.
C. M. Braidwood, Lapeer, to Elba, Mich.
A. J. Black, St. Louis, to Wilton, Mo.
John Curwen, Warren, to 325 N. Front St., Harrisburg, Pa.
C. S. Hosmer, Nephi, Utah, to 406 E. Liberty St., Ann Arbor, Mich.
J. T. Hubel, 495 Gratiot Ave., to 460 Brush St., Detroit, Mich.
Elmer Lee, 9 W. 45th St., to 127 W. 58th St., New York City.
E. H. Moore, Whitehouse Station, N. J., to N. Y. Post-Graduate Med. School, New York City.
J. H. F. Mullett, 1312 Geddes Ave., to 210 13th St., Ann Arbor, Mich.
A. L. McNay, Gray Summit, to Pacific, Mo.
R. G. Olson, Muskegon, Mich., to 948 S. Robey St., Chicago.
E. G. Randall, Oneida to Waterville, N. Y.
C. J. Roberts, Warren Tavern, to Malvern, Pa.
J. R. Scott, Appleton, to Hortonville, Wis.
W. J. Swartz, 93 Cambridge St., St. Paul, to 2604 Bloomington Ave., Minneapolis, Minn.
O. Tydings, Piqua, O., to 225 Dearborn Ave., Chicago, Ill.
W. J. Taylor, 121 S. 18th St., to 1825 Pine St., Philadelphia, Pa.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Sept. 20 to 26, 1900, inclusive:

Edward Barry, acting asst.-surgeon, from Fort Wadsworth, N. Y., to San Francisco, Cal., en route to Manila, P. I., for duty in the Division of the Philippines.

W. Fitzhugh Conter, major and surgeon, U. S. A., leave of absence granted.

George E. Chamberlain, acting asst.-surgeon, from South Newbury, Vt., to San Francisco, Cal., for duty with troops going to the Philippine Islands.

Weston P. Chamberlain, lieutenant and asst.-surgeon, U. S. A., relieved from duty in the Division of the Philippines, to proceed to San Francisco, Cal., and report by letter to the surgeon-general.

Jere B. Clayton, lieutenant and asst.-surgeon, U. S. A., from Vancouver Barracks, Wash., to Fort Myer, Va.

Marshall M. Cloud, lieutenant and asst.-surgeon, U. S. A., sick leave granted.

James B. Ferguson, acting asst.-surgeon, leave of absence granted.

William M. Hendrickson, acting asst.-surgeon, from Fort McDowell, Cal., to Fort Flagler, Wash.

James H. Hepburn, acting asst.-surgeon, leave of absence granted.

James H. Hysell, major and surgeon, Vols., relieved from duty in the Department of Eastern Cuba, to report to the surgeon-general at Washington, D. C.

Thomas J. Kirkpatrick, lieutenant and asst.-surgeon, U. S. A., from Fort Myer, Va., to Fort Barrancas, Fla.

William J. Lyster, acting asst.-surgeon, leave of absence extended.

Champe C. McCulloch, Jr., captain and asst.-surgeon, U. S. A., from Fort Barrancas, Fla., to San Francisco, Cal., en route to Manila, for duty in the Division of the Philippines.

John L. Nicholson, acting asst.-surgeon, from Dorchester, Mass., to San Francisco, Cal., for duty with troops going to the Philippine Islands.

Henry Page, lieutenant and asst.-surgeon, U. S. A., relieved from duty in the Division of the Philippines, to proceed from San Francisco, Cal., to Plattsburg Barracks, N. Y., for duty at that post.

William H. Spiller, acting asst.-surgeon, from the transport *Grant* to duty on the transport *Hancock*.

William T. Tanner, acting asst.-surgeon, from Fort Myer, Va., to duty at Fort Wadsworth, N. Y.

Stephen Wythe, acting asst.-surgeon, from Fort Flagler, Wash., to San Francisco, Cal., for assignment to duty in the transport service.

ASSIGNMENTS.

On September 26, 1900, the following assignments of medical officers of volunteers to the organizations and upon the dates specified after their respective names, as they appear of record in the War Department, were published:

Maj. John R. Hereford, surgeon, Jan. 26, 1900; Capt. William H. Cook, asst.-surgeon, Jan. 26, 1900; First Lieut. Frank W. Dudley, asst.-surgeon, Jan. 27, 1900, to the 32d U. S. Vol. Inf.

First Lieut. Raphael A. Edmonston, asst.-surgeon, Mar. 1, 1900; First Lieut. H. Brookman Wilkinson, asst.-surgeon, June 16, 1900, to the 34th U. S. Vol. Inf.

Maj. Eugene L. Swift, surgeon, Nov. 12, 1899; Maj. Luther P. Grandy, surgeon, Mar. 9, 1900; Capt. John A. Metzger, asst.-surgeon, Mar. 9, 1900; First Lieut. John Carling, asst.-surgeon, Mar. 9, 1900, to the 35th U. S. Vol. Inf.

Maj. Paul F. Straub, surgeon, July 12, 1899, to the 36th U. S. Vol. Inf.

First Lieut. Edward D. Sinks, asst.-surgeon, Aug. 14, 1899, to the 37th U. S. Vol. Inf.

First Lieut. George S. Wallace, asst.-surgeon, Aug. 30, 1900, to the 42d U. S. Vol. Inf.

Maj. Frank E. Artaud, surgeon, July 24, 1900; Capt. William C. Berlin, asst.-surgeon, July 30, 1900, to the 45th U. S. Vol. Inf.

Maj. Charles F. Kieffer, surgeon, Sept. 12, 1899; Capt. Howard A. Grube, asst.-surgeon, Sept. 12, 1899; First Lieut. William W. Purnell, asst.-surgeon, Sept. 13, 1899, to the 48th U. S. Vol Inf.

Maj. Robert Burns, surgeon, June 24, 1900; Capt. William C. Warmsley, asst.-surgeon, June 28, 1900; First Lieut. Joseph H. Carroll, asst.-surgeon, June 14, 1900, to the 49th U. S. Vol. Inf.

Maj. Alexander D. Ghiselin, surgeon, April 4, 1900; Capt. Shadworth O. Beasley, asst.-surgeon, April 4, 1900; First Lieut. Stanley MacC. Stuart, asst.-surgeon, April 4, 1900, to the 11th U. S. Vol. Cav.

Capt. José Lugo-Vina, asst.-surgeon, Mar. 28, 1900; First Lieut. Gustave Moret, asst.-surgeon, April 21, 1900, to the Porto Rico Regt.

Capt. Maxwell S. Simpson, asst.-surgeon, June 1, 1900, to the Squad. Phil. Cav.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy for the two weeks ending Sept. 29, 1900:

Surgeon C. T. Hibbett, detached from the Cavite naval station and ordered to the *Newark*.

Surgeon O. D. Norton, detached from duty with the marine regiment in China and ordered to the *Monadnock*.

Asst.-Surgeon F. L. Benton, detached from the naval hospital, Cavite, P. I., and ordered to the *Brooklyn*.

Medical Director J. A. Hawke, detached from the New York navy yard and ordered to duty at the naval hospital, Mare Island, Cal.

Medical Inspector G. P. Bradley, detached from the naval hospital, Mare Island, Cal., on reporting of relief, and ordered home and to wait orders.

P. A. Surgeon G. D. Costigan detached from the *Newark* and ordered to the *Yorktown*.

Asst.-Surgeon E. Davis detached from the *Yorktown* and ordered to the Cavite naval station.

Asst.-Surgeon M. K. Elmer detached from Boston navy yard and ordered to accompany battalion of marines to Mare Island, then to duty on the *Ranger*.

Asst.-Surgeon J. C. Thompson detached from the *Newark* on reporting of relief, proceed home and wait orders.

Asst.-Surgeon W. B. Grove, ordered to duty on the *Vermont*.

Asst.-Surgeon H. E. Odell, detached from the *Ranger* on reporting of relief and ordered to Asiatic station with battalion of marines for duty as relief of Asst.-Surgeon J. C. Thompson.

Surgeon B. F. Stephenson, detached from the *Baltimore* when out of commission; ordered to examination for promotion at Washington yard, thence home and wait orders.

Asst.-Surgeon W. H. Bell, relieved from additional duty at Norfolk Hospital and ordered to continue duty on the *Vixen*.

Asst.-Surgeon H. A. Dunn, previous orders modified, ordered to report for duty on *Dorothea*, instead of proceeding home.

Asst.-Surgeon K. Ohnesorg, detached from the naval academy and ordered to the *Vicksburg*.

Asst.-Surgeon A. Stuart, detached from the *Fortune* and ordered to resume duties on the *Yankton*.

Asst.-Surgeon E. V. Armstrong, ordered to report to commandant of New York yard for duty on the *Vermont*.

Medical Director C. U. Gravatt, commissioned medical director from August 24.

Surgeon G. B. Wilson, commissioned surgeon from February 7.

Pharmacist R. Waggener, ordered to duty at naval proving grounds, Indian Head, Md.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Aug. 10, 1900:

SMALLPOX—UNITED STATES.

Alaska: Port Safety Aug. 25; reported.

Colorado: Aug. 9-Sept. 11; Arapahoe County, 3 at Denver; El Paso County, 2; Fremont County, 3; Garfield County, 3; Glenwood Springs, 2; Huerfano County, 3; Las Animas County, 4; Pueblo County, 21.

Louisiana: New Orleans, Sept. 15-22, 6 cases, 2 deaths.

Michigan: Houghton, Sept. 8-15, 2 cases; Torch Lake, Sept. 8-15; 2 cases.

Ohio: Cleveland, Sept. 15-22, 6 cases.

Utah: Salt Lake City, Sept. 15-22, 3 cases.

Wisconsin: Sept. 18, Ashfield County, present; Bayfield County, present; Dane County, present; Eau Clair County, present.

SMALLPOX—FOREIGN.

Austria: Prague, Sept. 1-8, 1 case.

Belgium: Ghent, Sept. 8-15, 1 death.

Egypt: Alexandria, Aug. 28-Sept. 3, 1 case; Cairo, Aug. 18-26, 3 cases.

England: Liverpool, Sept. 1-8, 3 cases.

France: Lyons, Aug. 25-Sept. 1; 2 deaths; Paris, Sept. 1-8, 5 deaths.

India: Bombay, Aug. 21-28, 2 deaths; Calcutta, Aug. 11-26, 18 deaths; Madras, Aug. 11-24, 2 deaths.

Mexico: Vera Cruz, Sept. 8-15, 4 deaths.

Russia: Moscow, Aug. 25-Sept. 1, 1 death; Odessa, Aug. 25-Sept. 8, 7 cases, 1 death; Warsaw, Aug. 25-Sept. 1, 5 deaths.

Scotland: Dundee, Aug. 25-Sept. 1, 2 cases; Glasgow, Sept. 7-14, 31 cases.

Spain: Madrid, Aug. 11-Sept. 1, 111 cases.

YELLOW FEVER.

Cuba: Cienfuegos, Sept. 22, 1 case; Havana, Sept. 8-15, 9 deaths.

Mexico: Vera Cruz, Sept. 8-15, 15 deaths.

PLAGUE—FOREIGN.

India: Bombay, Aug. 21-28, 64 deaths; Calcutta, Aug. 11-25, 136 deaths.

Scotland: Glasgow, Aug. 31-Sept. 14, 16 cases, 1 death.

CHOLERA.

India: Bombay, Aug. 21-28, 408 deaths; Calcutta, Aug. 11-25, 29 deaths; Karachi, Aug. 19-29, 13 deaths; Madras, Aug. 18-24, 37 deaths.

Japan: Yokohama, Aug. 25-Sept. 1, 1 case.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

The Journal of the
American Medical Association

Vol. XXV. CHICAGO, ILLINOIS, OCTOBER 20, 1900. No. 16.

Original Articles.

REPORT OF THE COMMITTEE ON TUBERCULOSIS.

At the Columbus meeting of the American Medical Association, June 6-9, 1899, the following resolutions were adopted:

Resolved, That the president appoint a committee of five with power to add to that number, who shall prepare a report on the nature of tuberculosis; its communicability and prevention; the more effectual means of controlling the spread of infection and of educating the people in personal hygiene, so as to lessen the chances of their becoming tuberculous and to increase the prospects of their recovery; the advisability of establishing national and state sanitoria, and such other matters as may be pertinent to the subject.

Resolved, That this committee shall present this report to the Congress of the United States and to the legislatures of the various states of the Union and urge upon them that appropriate measures be speedily taken.

To the President and Members of the American Medical Association:

Gentlemen:—Your Committee on Tuberculosis appointed in pursuance of a resolution of the meeting of 1899, was instructed to report on the general subject of tuberculosis, as to: 1, its nature; 2, its communicability; 3, its prevention; 4, the control of the spread of the disease and the education of the people so as to lessen their chances of infection and their prospect of recovery when infected; and 5, on the advisability of national and state sanatoria.

In presenting this preliminary report your committee finds it unnecessary to deal at any great length with the first two sections of the subject assigned.

1. Tuberculosis is a disease of many tissues of the body, due to the growth therein of the tubercle bacillus, which finds for some reason a favoring culture field in the organs. Granular minute bodies, known as tubercles, are produced, whose tendency is to necrosis and the setting up of the process of suppuration. Poisoning of the system in varying degrees results from both of these processes, and important organs and functions are interfered with and so death follows in a large proportion of cases.

The exact mortality of tuberculosis can not be stated, for all the cases can not be counted, since many are undiagnosed and many are suppressed; but in this country it probably amounts, in towns, to not far from 14 per cent. of all deaths, and it is easily demonstrated that the pulmonary form reaches 9 to 11 per cent. of all deaths. In the country, as a whole, the mortality from all forms of tuberculosis is probably considerably below 14 per cent.; possibly not over 12 per cent. In upward of forty towns and cities of the United States, which for the year 1897 reported their deaths from consumption, the mortality from this disease was 10.9 per cent. of the total mortality. Tuberculosis kills thirty times as many as die from smallpox and scarlet fever together, and four and a half times as many as from these two diseases with typhoid fever and diphtheria combined. The figures thus show that this is the most destructive disease extant. It is, moreover, the one least subject to fluctuation; the most constant from year to year. Domestic animals furnishing the food of man are afflicted with it, and bacilli are found in the milk and butter derived from them. It is intertransmissible with them.

It is difficult to state the morbidity of human tuberculosis. Pathologists give varying figures as based on post-mortem examinations, of 40 to 75 per cent. of all people as being afflicted with it in some portion of their bodies some time in their lives. Probably a fairer figure would be 50 per cent.

2. Tuberculosis is a communicable disease; is carried from person to person as a specific bacterium which enters the body and thrives variously or dies, depending on the personal susceptibility of the individual. This varies in different bodies and in the same body from time to time, and is increased by ill-health, unhygienic conditions of life, starvation and overwork, and by hereditary predisposition. It is decreased by bodily vigor, outdoor life, good hygiene and perfect physiological functions.

Tubercle bacilli are very prevalent in the atmosphere of cities and towns, and not all people who imbibe them take tuberculosis, but only those with a power of resistance that is too low either to destroy them or to render them innocuous.

The bacilli are acquired mainly through the air, which carries them directly into the mouth, nasal passages, throat, trachea and lungs. Bacilli taken into the mouth and throat are mostly swallowed, and, if not destroyed by the acids of the stomach, pass into the intestines, sometimes to set up tuberculosis there. The microbes are doubtless often swallowed in milk, and are carried to the mouth by polluted utensils, by things chewed, and possibly by the kiss of infected persons. Some bacilli find their way into the lymphatics and blood-vessels, and so are disseminated through the system, possibly to start foci of disease in distant parts of the body.

3. As to prevention a larger word is to be said. Complete suppression of the disease is too much to hope for, but it is possible to limit to some degree the spread of it, and the necessary measures should engage the most earnest and sustained attention, and have the insistent support of every member of the medical profession. The first step to the accomplishment of this end is to reduce the number of tubercle bacilli in the air we breathe. The disease is largely air-borne, and our duty is obvious. The following are practical measures: *a.* Destruction as far as possible of all tuberculous sputum, either by fire or by chemical agents in spit receptacles. *b.* Careful disinfection of contaminated clothing, utensils and rooms—clothing and utensils by heat, either dry or moist, and rooms by formalin. *c.* Careful management of the patient in his person, and especially as to his expectoration. *d.* The segregation of infected persons, in whom the disease is active, under the care of nurses competent to prevent them from contaminating the atmosphere.

The next step is to protect food-stuffs, especially milk and meat, from contamination. This necessitates the careful and constant inspection of dairy herds, the creation and enforcement of wholesome rules of [illegible] and [illegible]truction of all seriously sick cattle.

Then the people, especially [illegible] posed to the disease, need to be [illegible] of robust, not to say athletic, [illegible]d-ard is dangerous. Comparative freedom from contact with the bacilli is the greatest desideratum; it is only less important, as people can never be wholly free from them, that they should have the greatest power to resist their multiplication in the body. The largest influences to this end are a life much in the open air and perpetual freedom from every excess in any possible direction.

4. How can the people be educated to prevent the spread of tuberculosis, and when infected how can they have larger hope of recovery?

The lessons on this point should be as few as possible, so as to avoid confusion and the scattering of public attention. They should be consistent, and contain nothing unnecessary. A few cardinal doctrines ground into public thought will be more effective than a hundred casual details. They should carefully avoid unproved theories and impracticable measures; nothing blights a good reform movement so surely as these. They should be such, and only such, as will command the unanimous approval of the profession, so that there shall be no confusion of tongues or advice. They should be limited, in the burdens they impose on the public, to such measures as will appeal to its common sense, and not provoke antagonisms or unnecessary hardships. These are cardinal truths: *a.* We must enlighten the people as to the nature of tuberculosis and the method of its distribution. *b.* The urgent sick should, if convenient, be segregated somewhat from the well, and be sent to sanatoria if possible. If they live with their families they should know and obey the rules of proper personal care and conduct. The practice of keeping consumptives ignorant of the nature of their disease, when they are expectorating billions of bacilli every day, is a crime against the community. They are usually less shocked by the truth than their friends are, and knowing it, they are more ready to join in measures for their own good and for the protection of others. *c.* All spitting on floors, sidewalks and public conveyances must be discouraged and forbidden by law. Expectoration should be received into articles that can be burned or disinfected, and its destruction should be insisted upon. Long exposure to sunshine kills the bacilli, but when infected sputum is cast out upon the ground the possibility is great—except in regions of the most intense sunshine—that before it is rendered harmless it will become to some degree part of the dust of the air, to the danger of the community. *d.* The tuberculous must not wear long beards, nor allow their mouths to carry infection to others; and contaminated clothes should be frequently sterilized by heat. At least in the houses of expectorating tuberculous patients, carpets are an abomination, and the sweeping of rugs even should be forbidden. *e.* The truth should be inculcated that only the most scrupulously careful patients of those who expectorate much can avoid contaminating their clothes and articles about them, and that, therefore, the watchfulness should be perpetual. *f.* It requires most exceptional nursing of a consumptive who expectorates much, to prevent contamination of his room. Therefore it ought to become public policy that health officers should, in their discretion, as a general rule, when they receive reports of death from pulmonary tuberculosis, require that the rooms in which the patients died shall be immediately disinfected. The only exceptions should be where the proof is positive that perfect cleanliness has been maintained throughout the sickness. *g.* The people ought to be instructed that when one is seized with tuberculosis—especially that form which leads to consumption—there should be immediately adopted a radical plan of management of the case, to include, as far as possible: a reduction in labor and care; a change in surroundings and conditions of life; a life either quite out-of-doors, or, if in-doors, with as much fresh, pure air as possible; the greatest amount of rest and sleep; the best nourishment suited to delicate digestion, and taken oftener than is usual in health; and a sharp reduction in exercise if fever is present. Conservative medical treatment, to be prescribed by the physician, is useful but secondary. The foremost purpose must be to increase the resisting power of the body to the disease. Thus only does recovery come, and the greatest single measure to this end is probably the out-door life. Consumptives should become out-door instead of in-door animals. The chief advantage of good climates for the disease is in the possibility of the patient's living out of doors, although dryness of air is valuable and altitude has benefit for many cases. *h.* Nothing will be gained in this day and generation by attempting to secure by law the reporting to health officers of all cases of tuberculosis. Many physicians will never report their cases frankly; they will hide them, treat them under inaccurate and unscientific diagnoses, conveniently forget and even prevaricate, and their patients will sustain them. Such laws already enacted are dead. It has been and will be found impossible to execute such a rule, as to any disease that is never epidemic, but invades the bodies of half the people, many of whom go about in apparent health for years, and forget that they are seriously sick. And even if the health departments had the reports they could not serve any useful purpose except for statistical generalization; a purpose that is frustrated by the comparative worthlessness of all such records. *i.* All tuberculous farm stock, especially all animals whose bodies or products become food, if manifestly sick must be destroyed, and at public expense if not otherwise. But many mildly tuberculous cattle, like men, recover when given a better physiological chance; and recent events have shown that legalized attempts to destroy, to the burden of the community, large numbers of domestic animals that have all the appearances of health, sometimes meets with such opposition as to frustrate the whole beneficent scheme. We ought to have known and expected this, and it is pertinent to ask if it is important that meat shall be always free from a final few tubercle bacilli, that are killed by cooking, when fed to people a large percentage of whom have live bacilli in their own bodies. It would be better to try to educate the people to pasteurize their milk and always cook their meat, and to adopt a temperate destructive policy as to cattle, and a strenuous policy of care and segregation of slightly tuberculous stock, rather than, with measures that are open to the fair charge of being too radical and sweeping, to arouse a reaction that shall every few years sweep from the statutes of a state all the really necessary laws of this kind.

5. The sanatorium idea is increasing in this country. It is becoming popular as it has grown in popularity abroad, and it offers the greatest hope for tuberculous patients. The people are beginning to discover the value of regular sanatorium management for the cure of this disease. The cure depends vastly on an increase of the specific resisting power of the patient, and this can be accomplished best by hygienic measures carried out faithfully without a break for many months at a time. Fresh air, out-door life and a regimen of rest, diet, exercise and sleep which tend to increase the physiological forces that destroy or repress the bacilli, are the most important measures. Patients *may* carry out these measures by themselves, under advice and with a special nurse for each case, but usually they do not, but blunder at least one day in the month, by some excess or omission, and so neutralize all their previous gain. The sanatorium properly managed offers the best means up to this hour, for the cure of the average case.

The world was slow to learn that the sick with acute diseases deserve to be nursed by expert hands; that the trained nurse, moved by professional ambition and pride of success, makes for comfort and recovery to a patient, better than the casual care of unskilled strangers, or the agitated excess of inefficient friends. We are only just learning that people in the slow clutch of the most mortal of all maladies deserve a similar expert skill in their care, and to have it continued without interruption through the months and years if need be. The victim of a familiar, creeping death that is avoidable, is as much entitled to consideration as if he had the swift plague. Our virtue is apt to be spasmodic; we rouse ourselves for the relief of imminent disaster. It is a soberer and wiser virtue that creates and sustains measures to repress an insidious calamity.

Sanatoria for consumptives should be established all over the country. They are springing up with encouraging rapidity, but nearly all of them, so far, are for the people able to *pay. The majority of patients are unable to pay for institution care or for change of climate, and they are as deserving as any. To these the state owes a debt that is as genuine and urgent as any it owes to its other unfortunate citizens, and the state should erect and maintain sanatoria for them. Moreover, by saving the lives of a portion of these patients, and circumscribing the spread of tuberculosis, the state will always in the end be the gainer in wealth. We hold that it is the duty of* The American Medical Association, *not merely by the mouth of a committee on tuberculosis, but by its general membership as well, to urge on the legislative bodies of the states and the nation the surpassing necessity of these measures.*

6. There has been much discussion during the past year over a proposition to exclude by quarantine regulations, consumptives from two states of the union that have been resorts for such patients. We are not aware that the suggestion has even been seriously considered by any medical body, or by the profession at large. But it is true that there has grown up among some of the citizens of those states an impression that all of the recent increase of tuberculosis originating within their borders is directly chargeable to the numerous cases that have migrated to them. This is probably in part true. But these regions have more and more vivid sunshine than other parts of the country, so that bacilli that are out of doors are more likely to be killed. The contamination of the localities, if it has occurred, is most probably from infection of habitations through ignorance and carelessness; and this is an argument for the institutional care of as many cases of tuberculosis as possible, and for disinfection of certain houses, as we have recommended.

Whatever else the states referred to, or other resorts for consumption may or ought to do for their own protection, we are convinced that it will be impossible to do it by general exclusion. Not 10 per cent. of the cases journeying thither could be excluded by the most rigid quarantine, and any effort to do this effectively would arouse intense popular opposition, as the mere discussion of the subject has done already. At the same time it would tend inevitably to divert attention from the proper care of the cases from day to day, as the only feasible means of protection for the public.

Norman Bridge,
W. A. Evans,
Paul Paquin,
Committee.

RESOLUTIONS ON TUBERCULOSIS ADOPTED BY THE SECTION ON HYGIENE AND SANITARY SCIENCE.

Whereas, There is large demand for official statement relative to some of the questions pertaining to tuberculosis; therefore we

Resolve, That, 1. It is best that the policy of medical societies, medical officers and medical men be one of education;

2. Steps for the suppression of tuberculosis in this country must be so gradual that organized opposition shall not be engendered;

3. It is the duty of every national, state and municipal government to distribute tracts, arrange for lectures, and in every feasible way educate the people along the following lines: a, tuberculosis is contagious; b, it is preventable; c, it is curable; d, it is eradicable;

4. Every citizen of the United States having tuberculosis should have the privilege of living in a tuberculosis hospital; every such citizen should be strongly advised to accept such privilege;

5. Hospitals for cures are almost as essential as hospitals for homes;

6. A temporary residence in a tuberculosis hospital (if the patient can not remain) is desirable, as in such a residence hygienic laws, regulation of expectoration and danger from contagion can be inculcated;

7. Crowding, bad ventilation and bad drainage are potent factors in the propagation of the disease; this applies as strongly to animals as to man;

8. The present method of arrangement and management of eleemosynary institutions, and especially those in which restraint is a factor, are productive of tuberculosis;

9. The condition of the animals furnishing food in the vicinity of large cities is a subject for consideration by the authorities;

10. While American statistics are so incomplete as to be misleading, nevertheless, it is our opinion that the death-rate from tuberculosis in this country (rural and town population together) *does not exceed one-ninth of the death-rate from all causes;*

11. While the number of people dying from tuberculosis appears to be decreasing, nevertheless, excluding pneumonia, tuberculosis destroys more lives than all the remainder of the contagious diseases combined;

12. This Section should continue a committee on tuberculosis;

13. The proceedings, papers, statistics, etc., of this committee should be published;

14. That the secretary of this Section be instructed to communicate with the business committee of the general Association relative to these resolutions.

STATE PROVISION FOR THE TREATMENT OF THE CONSUMPTIVE POOR.*

BENJAMIN LEE, A.M., M.D.
Secretary of the State Board of Health of Pennsylvania.
PHILADELPHIA.

The only ground on which state charities can be justified is that of self-protection. In the case of the dependent classes, such as the insane, the deaf-mutes and the blind, protection against injury to life and property, or against the loss to society arising from enforced idleness and lack of education on the part of the sufferers, furnishes the excuse. In the case of infectious diseases, the danger to health and life from the extension of such disease justifies the erection of contagious-disease hospitals of all kinds and the expenditure of large amounts of money in the establishment and maintenance of quarantine stations. The foundation and support of hospitals simply for the relief of suffering and healing of diseases is, from the standpoint of strict political economy and true statesmanship, a flagrant misuse of public funds, and leads to serious abuses.

In the year 1898, the legislature of Pennsylvania appropriated more than three-quarters of a million dollars for the support of general hospitals, every one of which should have been sustained entirely by the community to whose poor it ministered. To lavish the public wealth in this way is simply to create a fund for the manufacture of paupers.

It is only the comparatively recent but now universally accepted discovery of the communicability of tuberculosis which has made it possible for a sanitarian to urge the state to contribute to the care of the consumptive poor, as such. So long as consumption was simply due to heredity and general environment, such a plea had no basis in any proper conception of the duty of the government to the individual. Granted that one person in fifty was affected with tuberculosis, and that there were over a million and a quarter cases of consumption in the United States, what business was that of the state? People must die of something. Why not as well of consumption as of heart disease or Bright's disease? And if there was suffering among the poor consumptives, that was a matter for consideration and relief by private philanthropy. But once admit that consumption is an infectious and therefore a preventable disease, and presto, the whole situation is changed. The state is losing tens of thousands of valuable productive lives prematurely and unnecessarily every year. Thousands more are wasting their time in taking care of those who are thus slowly dying. Here is a terrible leak in the public resources, a leak which we now know how to stop and which, therefore, we must stop. That which would before have been an unwarrantable and vicious use of the public treasure now becomes an imperative duty on the part of the state as the custodian of the material prosperity of its people. To put the matter in a nutshell, preventive medicine is the legitimate work of the state, remedial medicine is not, except so far as it may incidentally be preventive.

---

*Presented in a Symposium on Tuberculosis, in the Section on Hygiene and Sanitary Science, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

On the evening of the tenth day of January of the present year, a meeting of great interest in this regard was held in the city of Philadelphia. This was a joint meeting of the Philadelphia County Medical Society and the Pennsylvania Society for the Prevention of Tuberculosis. The subject for discussion was "The Duty of the State Toward Those Afflicted with Pulmonary Tuberculosis." It may not be generally known that many members of the Pennsylvania Society for the Prevention of Tuberculosis are not physicians. The object of drawing together associations thus differently constituted, was, as stated by the president of the Philadelphia County Medical Society, "through joint discussions to bring about more intelligent co-operation between physicians and the members of the general community in the preservation of the public health." All of the liberal professions and the mercantile community were represented among those who read papers or participated in the discussions. The subject was therefore treated from many standpoints, and in each instance by one well qualified by experience to speak. Boston and New York as well as Philadelphia contributed to the interest and value of the occasion. What I shall say at the present time will be mainly gathered from the report of this meeting, and I shall make no further apology for borrowing either the arguments or the facts then presented. I have already had occasion to call the attention of this Section to the admirable work of the Pennsylvania Society for the Prevention of Tuberculosis, and to urge upon members the importance of establishing similar societies in their own cities and states. The founder and first president of this society, Dr. Lawrence F. Flick, of Philadelphia, read the first paper of the evening, in which he unfolded the plans of that association. Their program was first of all education, not of the legislators only, but of the entire people. For this purpose great numbers of tracts, clearly expressed, in popular style, had been distributed, on such subjects as, "How Individuals Can Avoid Consumption," "How Consumptives May Avoid Giving It to Others," "What Storekeepers, Hotel-keepers and Others Might Do to Aid in Its Prevention." The registration of tuberculosis, both in human beings and domestic animals, is also urged. But beyond all other measures in practical efficiency was placed the establishment of hospitals and sanatoria for consumptives. It was claimed that in England during the last half century a reduction of 50 per cent. in the death-rate from consumption had been brought about by the establishment of consumptive hospitals. There would be not the slightest necessity for compulsory isolation even were it considered important, as hundreds of poor consumptives are knocking at hospital doors for admission and are turned away hopeless, to suffer, linger and die, and in the meantime communicate the disease to their families and infect the houses in which they live. From having been considered a hereditary, incurable and ineradicable disease, consumption is now, on the contrary, looked upon by the profession as: 1, not hereditary but acquired; 2, as to a considerable extent amenable to treatment, and, 3, as possible of eradication as a scourge of the race by known methods. It is safe to claim that at least 20 per cent. can be cured, and 10 per cent. more can have the disease arrested, which amounts practically to the same thing. In Dr. Turban's sanatorium, at Davos, in Switzerland, of those in the third or advanced stage, 23.6 per cent. were absolutely or relatively cured, and 17 per cent. were found to have remained so, when communicated with, years later.

The results obtained by the establishment of sanatoria for consumptives as private enterprises in Europe, and notably in Germany, were so gratifying as to lead the charitably inclined to feel that a burden of responsibility had thus been laid upon them for the extension of opportunities of this kind to those who were unable to pay for them. To such an extent has this idea been realized that in England there are now accommodations for about 5000 of these sufferers, either in hospitals for advanced cases, or in sanatoria for those in the earlier, more curable stages. In the city of London there are six special hospitals of this kind. In the city of Philadelphia we have four. These are, 1, the Home for Consumptives, connected with which is the House of Mercy, for male consumptives, conducted by the Protestant Episcopal City Mission; 2, the Rush Hospital; 3, the Free Hospital for Poor Consumptives, which at the present time simply avails itself of certain wards in existing hospitals, and 4, the Jewish Hospital, which has set apart ten free beds for consumptive patients. The first named accommodates and treats an average of 119 patients annually; the second about 70, and the third 40.

In addition to these, the Philadelphia Hospital, connected with the Almshouse, has certain wards set apart for consumptives. But, "what are these among so many?" In the year 1898 the deaths from consumption in that city were 2590. The provision for the treatment of poor consumptives was actually for 297. The financial loss to the city from these premature deaths may safely be put down at $2,590,000, to say nothing of the loss of production during long illness. The state of Pennsylvania cares for 6000 insane, 3000 feeble-minded, deaf and dumb and blind, and 12,000 paupers. At least 15 per cent. of the insane die of tuberculosis, and yet no adequate special provision is made for their care by the state. General hospitals are justified by their responsibility for the health of their other inmates, which would be endangered by the presence of consumptives, in refusing the latter admittance to their wards. With our present knowledge such an intermingling, so far from being an act of mercy, would be little less than a crime. But it is not less a crime to allow this immense class of sufferers to go without hospital opportunities for care and treatment. The legislature of Pennsylvania passed an act some years since, appropriating the sum of $50,000 for two years, to be used by the State Board of Health, under certain restrictions, for the suppression of epidemics, prevention of diseases, and protection of human life in times of disease and disaster, when, in the opinion of the board, the conditions are so grave that "the local health authorities and individual and organized charity are unable to meet the emergency." It would be impossible to lay down in more definite terms the nature of the responsibility of the state for the furnishing of medical aid, or the limitations which should control such action on the one hand, or on the other to describe more accurately the character of the dangers which constantly threaten human life in the prevalence of consumption. They are of such enormous proportions that the local authorities and individual and even organized charity are utterly unable to cope with them. But we have, unfortunately, become so habituated to them that to declare that they constitute an "emergency" would only provoke a smile on the part of the officials who are entrusted with the disbursement of the fund. It has come to be considered the proper thing that one-seventh of our population should be cut off in the middle of its days, at the time of its greatest value to the state, by this single scourge. Hence, it becomes the duty of those who do appreciate the true proportions of this problem to become missionaries to spread abroad the knowledge both of the curability and the preventability of consumption, and at the same time of the necessity for hospital provision on a generous scale to secure these ends. Once the public has thoroughly grasped these ideas, legislators will not be slow in yielding to the pressure which will be brought to bear upon them for making such provision. In Europe this movement is already making encouraging headway. In Germany, France, Great Britain, Sweden, Belgium, Holland, Spain and Roumania much has been accomplished. As is well known, so great an interest has been excited that an International Congress of Tuberculosis has been held, attended not only by physicians and philanthropists, but by government officials and members of royal houses. The Swedish parliament recently voted 850,000 crowns for a sanatorium for consumptives in South Sweden and a gift of 2,200,000 crowns from the people to King Oscar has been, with a liberality as intelligent as it was generous, devoted by him to the establishment of similar foundations in northern and central Sweden. In this country we are not without encouraging signs. The New York State Board of Health has adopted resolutions urging the early construction of a State Sanatorium for Consumptives in the Adirondacks, at a cost of not less than $200,000. The legislature of that state has already pased a bill authorizing large cities to establish hospitals for sufferers from tuberculosis. Massachusetts has already in operation an institution of this kind at Rutland, which cost $150,000. In Illinois an effort is being made, with fair prospect of success, to obtain the assistance of the state in erecting a sanatorium to accommodate 300 patients. Similar enterprises are under consideration in Indiana and other states. In Pennsylvania an admirable site, comprising about five hundred acres on a mountain slope of about 1250 feet elevation, has been offered to the Pennsylvania Society for the Prevention of Tuberculosis, so soon as the funds can be obtained either from individuals or from the legislature for erecting the necessary buildings. The United States Government has established a sanatorium at Fort Bayard, N. M., for the care of such of its soldiers as may become affected with the disease. A movement which has already achieved so great a measure of success can not be stayed. The day is certain to come when state governments will recognize their responsibility in this regard, and there are those present who will live to see, in consequence, an immense diminution in the prevalence and mortality of a disease which at this moment is disabling to a greater or less extent a million and a quarter of the people of this country and which kills four and a half times as many as smallpox, scarlet fever, typhoid fever and diphtheria combined.

SOME THOUGHTS ON OVERCROWDING AND TUBERCULOSIS.*

S. A. KNOPF, M.D.
NEW YORK CITY.

I have been requested by the Secretary of the Committee on Tuberculosis, appointed by the President of The American Medical Association, to write a few words on the etiology of tuberculosis, more particularly on the relation which overcrowding bears to the frequency of consumption. To offer something new in this line is really difficult, for the subject has been treated so many times by abler minds than my own.

In some of my previous publications[1] I have spoken of numerous visits made to the tenements of New York, of the heartrending conditions I have found there among consumptives, and of the sweatshops as agents in the propagation of disease, but, after all, I presume it can not be repeated too often that the tuberculosis problem, especially in our large cities, will never be solved unless we begin by improving the sanitary condition of the tenements. There should be laws to make the building of any but model tenement houses impossible, and overcrowding should be made punishable. Let this inhumanity to man no longer be permitted. Let the greedy owner of the dark, filthy tenement house, who is not content unless he makes 18 per cent. on his investment, feel the strong hand of the law whenever by the violation of the health ordinances the lives of his tenants become endangered. How can we ever hope, even with numerous sanatoria and special hospitals, to reduce in any marked degree the morbidity and mortality from tuberculosis, as long as we allow the main conditions which favor the propagation of the disease to exist or to be daily created anew? First among these we must mention the conditions which have a tendency to undermine the constitution, bringing about a state which we might call physiological poverty, that is to say, a condition in which the natural organs of defense are no longer capable of throwing off pathogenic micro-organisms, to the inhalation of which all of us are perhaps more or less exposed. A family of from six to ten, living in three rooms, of which perhaps one only receives direct light and air, can not possibly remain in a state of health for any length of time. The vitiated air is breathed over and over again, and even the desire for breathing naturally and deeply, if it ever existed, will become less and less. But besides this lack of air and light, intemperance and underfeeding—two evils which to my mind are not infrequently the result of the overcrowding of the cheerless homes of the toilers—aid to create in the human organism the very best soil for the invasion, growth and development of the tubercle bacilli.

The second condition which favors the propagation of tuberculosis is the almost absolute lack of precaution taken by consumptive patients dwelling in these tenements to dispose of the infectious sputum. These patients, still able to be about, will disseminate their disease by expectorating indiscriminately in the dark hallways, in their workshop, or wherever they may happen to be. The patients in the more advanced stages of the disease, who, owing to lack of hospital facilities, must remain in the dark bedrooms where any effective prophylaxis is impossible even with the best intention, constitute, of course, permanent local centers of infection.

---

* Presented in a Symposium on Tuberculosis, to the Section on Hygiene and Sanitary Science, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] "Pulmonary Tuberculosis; Its Modern Prophylaxis and the Treatment in Special Institutions and at Home." P. Blakiston's Son & Co., Philadelphia, 1899. "The Tenements and Tuberculosis," The Journal, May 12, 1900.

Some phthisio-therapeutists and sanitarians think that the compulsory reporting of all cases of consumption would materially reduce these foci of infection. The impracticability of such measures seems evident when we consider that nearly every sixth individual is suffering from tuberculosis in some form or other. Even where such laws exist my experience has convinced me that the cases not reported and not treated are more numerous than the reported and treated ones, and that those once reported, if not taken to a special institution, will often be obliged to move, or will move voluntarily, and so again sight and control of them are lost.

We must do away with the overcrowded, dark, dreary, dirty tenements of our cities, which foster intemperance, immorality and crime, and which by depriving the individual of pure fresh air and sunlight predispose strongly to tuberculosis and other diseases.

Houses built on damp soil, whether in cities or country, should be torn down, for no matter how perfect the sanitary arrangement of the building may be, damp soil will foster tuberculosis.

Reporting and even sending a sanitary inspector can have no lasting beneficial effect when the consumptive invalid of the family is obliged to continue to live under conditions which are in themselves phthisio-genetic. I am an ardent believer in individual and general public education in regard to prophylaxis of tuberculosis, and I am the last to underestimate the value of such instruction, but the best fruits can come from it only when we can offer to the consumptive dweller of the tenement ways and means to do better, or to get out of his unhealthy environments. Our present knowledge in phthisio-therapy has taught us that a tuberculous patient may be successfully treated wherever there is plenty of air and light. Not only tuberculosis, but many other diseases will disappear in proportion to the number of model tenement houses created by the efforts of our statesmen, municipal governments, or the individual efforts of philanthropists.

We must have sanatoria and special institutions to treat the curable and isolate the hopeless consumptive poor; but we must have a far greater number of model tenement houses, built on good soil, with good drainage, houses where sunlight can enter in abundance, where overcrowding is impossible, and which are constructed in a manner that pure air can have access to every room; where privacy is guaranteed and where the honest toiler will find pleasure in remaining at home. Give to the workingman a pleasant, clean, healthy and comfortable home and the rumshop will have fewer attractions for him. The money formerly spent for liquor will go to the butcher and baker for the better nutrition of himself and his family, and underfeeding—the other important phthisio-genetic factor—will be materially lessened.

The overcrowding of schools, bad ventilation of the classrooms, too much indoor work during school-life and not enough outdoor play will, of course, further any tendency to tuberculosis in childhood. Our city fathers, boards of education and teachers must unite in rational reforms. Consumptive school-teachers should not allowed to teach in public schools, neither should consumptive pupils be admitted to these institutions. For the latter school-sanatoria in healthy localities should be created, and the unfortunate tuberculous teacher in the incipient stage of the disease might here also find useful employment and regain health.

Overcrowded prisons, asylums and almshouses, of course, not infrequently contain numerous foci of tuberculous infection, and the close contact in which the prisoners and patients live, facilitates the propagation of the disease. More cubic space per individual, more systematic ventilation, and the isolation of tuberculous invalids are the remedies which should be urgently applied. The experiment in Alabama with a convict camp for tuberculous offenders seems an interesting and useful innovation in the line of modern prophylaxis of tuberculosis.

Ship-builders and ship-owners also should bear in mind that the intensely crowded quarters to which the average sailor is confined during his hours of rest and sleep are absolutely detrimental to his health, and even the outdoor life during the hours of work can not counteract the deleterious influence which the vitiated air of the forecastle exerts on the health of the brave seaman. A tuberculous sailor, still at work, is almost certain to infect his comrades, for there is hardly any class of people which live in more crowded quarters than the seamen. The ship-builders and masters of vessels must seek to remedy this evil.

Factories and workshops should be submitted to sanitary inspection to prevent the workrooms from being overcrowded, and to see that they are properly ventilated.

Lastly, the physicians, statesmen and philanthropists, interested in the solution of the tuberculosis problem, have, besides working for the better housing of the poor and the creation of special institutions for the treatment of consumptives, an additional mission to perform. The tide of emigration from village to city should be reversed. If tuberculosis has made its appearance in a family living in a large city the physician should exert all his influence to induce, especially the younger members, to migrate to the country and seek outdoor occupations. Statesmen should protect the interests of the farmer, so that farming will have more attraction to the rising generation than it has had in the last few decades; and philanthropists should aid the statesmen by endowing institutions for instruction in scientific and profitable agriculture, and also by providing healthful amusements in country districts, and thus make living outside of large cities more interesting.

The creation of schools of forestry in connection with the preservation and cultivation of forests in many states where a wasteful destruction of trees is now carried on, would give useful and healthful employment to a number of people, as well as render the regions more healthful. It would offer attractive careers to young men seeking to overcome hereditary or acquired tendencies to tuberculous diseases.

I submit these few thoughts on overcrowding and tuberculosis in the hope that they may be helpful to those who have the desire and the means to aid in the combat against the "great white plague."

16 West Ninety-fifth Street.

Igazol.—A committee was appointed to decide on the merits of Cervello's "igazol" in the treatment of tuberculosis, at San Paulo, Brazil, where it was tested on a large scale in one of the hospitals. The report, published in the *Revista Medica* of June 15, states that no favorable results of any kind followed its use.

CLIMATE FOR TUBERCULOSIS.*

NORMAN BRIDGE, M.D.
CHICAGO AND LOS ANGELES.

Climate is supposed to be the major force in the cure of consumption. It is important, but only one element in the proper management of this disease. The vital object is to increase the resisting power to the bacillus; everything that tends toward that end is important. Climate may be made to help toward it in some cases; but it does not always help—sometimes it hinders, and greatly does so. It is a pitiable waste when it does not help; it ought always to benefit somewhat or not be invoked. Many times it is worse than useless, and brings disappointment and chagrin where it ought to give comfort, and so throws discredit on the whole subject. A measure capable of so much good ought not to be discredited by the unwise use of it, or by unwarrantable belief in it. Fatuous faith leads to neglect of other needful things. Because climate is valuable and has great possibilities for good, there is no occasion for rhapsodies about it that are sure to curtail its usefulness for the numerous victims of the most pathetic disease ever known.

To increase the resisting power of the body—reduced in some part at least or the disease could not have started—is the great requirement. For this all the resources of the system must be conserved, and no influence that will increase the power can be spared. Increased susceptibility from reduced power comes of too hard work of body and mind, or some of the cells thereof, and so blood-making and capacity for bodily exercise are reduced.

The monotony of one kind of work with a narrow range of exercise always lowers the vitality. Practically there are no occupations that are entirely hygienic and conserve all the powers of life; and, especially, can no indoor work ever do this.

Monotony, work and worry lead to a lowering of vitality always, unless they are counteracted by sufficient vacations and change. The digestive power is reduced in this way; then blood-making fails and tuberculosis is invited. Fermentative and other poisons accumulate in the system as a result and militate against recovery.

The needs of the tuberculous patient are not one, but several, and apart from special medication include: 1, rest from work; 2, change of work and cares, so as to shift the load from parts that have borne it to those that are fresh; 3, painstaking attention to the digestion and the feeding and nutrition of the body; 4, long hours of sleep; 5, outdoor life, much sunshine, and fresh air every hour; 6, a change of surroundings for novelty and pleasure, and to help shift the load, and finally 7, a change of climate, to a better one if possible, but a change anyway. Not one measure, therefore, but seven, are needed, and change of climate helps or ensures some of the others, but not all, and, great as climate is, it is not everything.

The chief value of any climate for tuberculosis rests in the ability of the patient, without depression or hardship, or much labor to live a large part of the time out of doors and to breathe the pure air all night. This is many fold more valuable than all special treatments combined. The reason of all its value has probably not yet been explained; we simply know that we have in our houses and work-inclosures some influence that is detrimental, and that we can hardly hope to make the atmosphere of our habitations as good as that of the skies. We think we know all about the physics and chemistry of the atmosphere, but after a century we have found that there is an element within it—argon—that constitutes 1 per cent. of its bulk and which had eluded the chemists for all these decades. The value of the outer air is founded firmly on clinical evidence, whatever chemistry says.

Sunlight is a good element of a proper climate for tuberculosis. It helps the patients in body and spirits, and kills the bacilli that it can touch for a few hours. It probably also represses or destroys other harmful influences, and helps to keep the earth's surface free of too much water, a thing that is charged with spreading tuberculosis.

Altitude helps some cases, especially the incipient ones. It causes, for a time at least, an increase in the number of red corpuscles—of reduced size perhaps—and often starts an improvement in nutrition which may be the beginning of recovery.

Dryness of air is almost universally regarded, and justly so, as one of the best qualities of a proper climate. It minifies the surface earth water and counteracts its injurious influences; it increases the power of the sunshine to kill bacilli; it lessens the liquidity of the phlegm and reduces the amount of expectoration of consumptives, and calms the cough of many of them. That it has much influence on the march of the disease deep in the lung tissue, where the respired air can not touch, is not so well proved. These are the chief advantages of the best climate—advantages that are not likely to be discredited hereafter. But all climatic influences for good may be rendered nugatory, and often are, by lack of other conditions that are as vital as any that have been named.

Homesickness wholly counteracts any good effect of climate in many cases, and in others does worse. Patients are often sent away alone, severing all their previous associations and ties, and are expected to shift for themselves among strangers, to keep up their courage, and in the face of depressing symptoms to gain in health. The average of them can not do it, and friends or relatives or nurses should always accompany and care for them.

By managing their own diet and eating only when they are hungry, and such foods as fancy moves them to, they practice a moderate starvation when they ought to have forced feeding in six eatings each day. They believe that the more they exercise and develop their muscles the better, which is untrue; and they will force themselves as an act of duty and against their inclination to exercise when they have fever, and always to their great detriment.

They often select unwholesome rooms and nearly always keep housed with poor or no ventilation for full sixteen hours in the twenty-four. They have the most amazing fear of night air and of cold-catching; they can scarcely be convinced that night air is better to breathe than day air and that if the body is kept warm there is no danger of cold-taking from currents of air night or day.

Only those patients recover from pulmonary tuberculosis who have, under good hygiene and treatment, nearly enough resisting power within their bodies to counteract the disease. With other things as favorable as possible, or nearly so, a good climate—and a change from the home climate—is an influence that will often tip the balance in favor of recovery. Nothing more than this should be asked of any climatic resource, and it is extremely unwise to journey to a distant country at great inconvenience and expense, and to expect, by so doing, to excuse the omission and neglect of those measures of wholesome living for the sick, that can be had in almost any climate, and that are justified by the experience of all time, as well as by common sense.

TUBERCULOSIS—ITS ZOOLOGIC AND GEOGRAPHIC DISTRIBUTION.*

W. A. EVANS, M.S., M.D.
Professor of Pathology, Medical Department University of Illinois, and in Milwaukee Medical College.
CHICAGO.

Tuberculosis is the most widely spread of all diseases. This is true, whether we view the question from a zoologic or a geographic standpoint. This extent of distribution must be taken into account in determining the importance of the disease, the possibility of eradicating and the means of combating it. I will state first many somewhat isolated facts, and later I will draw conclusions.

ZOOLOGIC DISTRIBUTION.

Cattle.—Amongst domestic animals the cow is unquestionably most important from the standpoint of the danger from tuberculosis. The reason for this is that the one very abundant source of nourishment that is eaten raw is derived from the cow. The eating of uncooked meats, of half-done or smoked sausages, threatens a limited number of people. The drinking of milk threatens all the people. The artificial conditions under which milk cows are kept, the warm, snug, draught-free, and therefore dangerous, stables, the forced feeding and the continuous milking, in short, the strenuous life makes the milk cow very susceptible to tuberculosis. The proportion of tuberculosis amongst oxen is much smaller. The figures are about one-tenth as high as for milk cows. Calves and yearlings have about one five-hundredth as much tuberculosis as milkers have. The statistics of the Illinois Board of Live Stock Commissioners show that in the herds examined—mostly those of the peri-urban dairy districts—16 per cent. were tuberculous. In the herds of Wisconsin, where some suspicion of disease existed, tests have shown 10 per cent. of tuberculosis. A correspondent informs me that in Colorado around the cities 2 per cent. of the cattle are tuberculous; that in the range cattle there is none. Hirsch says that in the range cattle of Brazil there is no tuberculosis. Around the cities the generally imported dairy cows show 15 per cent. In the mountains of Switzerland and in the highlands of Hungary there is almost no bovine tuberculosis. In the dairy districts of North Germany 25 per cent. of the slaughter-house cattle, to say nothing of the dairy cattle, are tuberculous.

In Pennsylvania, the later figures of Dr. Pearson show that 11.6 per cent. of the milk cows examined are tuberculous. In Massachusetts in 1895-97 fully 30 per cent. of the milk cows examined showed tuberculosis. In Connecticut in 1896, 14 per cent. of 6304 cows examined were tuberculous. In the districts near the larger cities 29 per cent. showed the disease. In the more thinly settled districts 99 per cent. were tuberculous.

Horses.—Chauveau produced experimental tuberculosis in the horse and in the ass. Cadeac and Morot report two cases in horses. Thompson reports one case. Nocard says the horse is very refractory to experimental tuberculosis, but is very frequently affected by tuberculosis contracted in the ordinary way. Tuberculosis in the horse is of two distinct types, the pulmonary and the abdominal. Nocard is of the opinion that the pulmonary type is due to the human bacillus, the abdominal type to the aviary bacillus. The literature of comparative pathology and of veterinary medicine teems with reports of tuberculosis in the horse. This fact proves, first, that the disease is not exceedingly widespread, and, second, that it is fairly abundant. We are to bear in mind that post-mortem sectioning of the horse is the exception.

Hogs.—There is no question as to the prevalence of tuberculosis in hogs. The figures for Berlin, in 1893 to 1894, were .5 to .9 per cent. Johne says that, in Saxony, in 1891, 1.07 per cent. of the hogs slaughtered showed tuberculosis. Thomassen says that the statistics of Amsterdam showed 1 per cent. of tuberculosis in the slaughter-house hogs. The Rouen statistics showed .04 per cent. Tuberculosis in the hog is usually of the abdominal type. These figures gain importance when we recall that it is the thriftiest of all the yearling hogs that gets to the slaughter-house. The Copenhagen statistics show the effect of feeding hogs on the skim milk or slime from the creameries.

Goats and Sheep.—Colin has given tuberculosis to sheep by inoculation. Bollinger reports a case in sheep. Cadiot, Gilbert and Roger, Moule and Siegen report cases. Lydtin reports three cases in goats; Thomassen one. Colin produced the disease in a goat.

I have made post-mortems on two tubercular Aubeaus and two tuberculous mountain sheep, members of the goat and sheep family. The literature contains records of a moderate number of cases. Morrison says sheep and goats get tuberculosis when injected intravenously, or continuously fed on tubercle bacilli.

Dogs.—The museum of the New Veterinary College, England, contains a specimen of tubercular pericarditis in the dog. Villeman reported six cases of tuberculosis in dogs. Bertheau, Weichselbaum and Verageuth, Koch, Gamaleta, Maffucci, Zagari, Mallin, Wells, Johne, Marcus, and hundreds of others report one or more cases in the dog. I have seen a case of tuberculosis in a black wolf—a member of the dog family. Jensen found 15 cases in eleven months. Bang reported 13 cases. Eiber, at Dresden, posted 400 dogs, finding tuberculosis in 2.75 per cent. Cadiot posted 9000 dogs at Dálfort; in two years 40 per cent. showed tuberculosis. The disease in the dog is found especially in the lungs. Strauss says: "It is, above all, by reason of his cohabitation with men attacked by tuberculosis that tubercular infection occurs in dogs." Johne reports a case confirming this view. Czoker reports four similar cases.

Cats.—Villemen produced experimental tuberculosis in a cat. Viseur made a cat tuberculous by feeding it the tubercular lungs of a cow. This was confirmed by Nocard. Jensen at Copenhagen posted 25 tuberculous cats in two years. Davis reports one case in a cat. I have held post-mortems on three tuberculous lions and one tiger—members of the cat family.

Rabbits and Guinea-Pigs.—While these animals are habitually used for experimental tuberculosis, and possess a very great susceptibility, they seldom contract the disease spontaneously. Strauss says: "Rabbits and guinea-pigs are very rarely the subject of spontaneous tuberculosis."

---

* Presented in a Symposium on Tuberculosis, to the Section on Hygiene and Sanitary Science, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Barn-yard Fowls.—Tuberculosis is very frequently found in nearly all the varieties of domestic fowls. Strauss says that it is found in roosters, hens, pheasants, turkeys, pigeons, canaries, finches, ostriches, swans, vultures, owls and carnivorous birds, as well as grain feeders. Zurn, in posting 600 chickens, found 10 per cent. tuberculous. The Rhode Island Experiment Station found 15 per cent. of a lot of incubator chickens tuberculous. Bouley, Devillers and Leugleu cited cases to prove that chickens could contract the disease from being among tuberculous people. Ribbert confirms this. Johne, Mollereau, Chelkowski, De Lamelleree, Cagny, Koch and Nocard publish some confirmatory facts. Bray, of Kansas City, reports an infection of a poultry yard by a man with tuberculosis. Strauss sums up the question as follows: "It appears, then, to be established that fowls can become tubercular from eating the excretions of tuberculous animals." Nocard has demonstrated that the avian form of the tubercle bacillus is a modification of the human, just as Theobold Smith has demonstrated certain differences between the human and the bovine forms. Strauss says that ducks and geese are very refractory. He quotes Pomay's experiences, showing that in a poultry yard in which a great many chickens and turkeys died of tuberculosis, the ducks and geese, living right with them, remained healthy.

Menagerie Animals.—Strauss reports a post-mortem made by himself on a tuberculous lion in the Paris Zoological Garden. During the last two years I have posted three tuberculous lions in Lincoln Park Zoological Garden. In addition to this, I have found tuberculosis in the following animals: one tiger, one black wolf, one rock python, two mountain sheep, two elk, two antelopes, two species of goat, fifty monkeys of all species and kinds.

In the London Zoological Garden, according to Forbes, 43 per cent. of all the monkeys die of tuberculosis. In the Paris Jardin d'Acclimation 20 per cent. of the deaths are due to tuberculosis. In the Zoological Garden, Frankfurt-sur-le-Main, 22 per cent. die of this disease. In my observations, extending over two years, tuberculosis has caused 94 per cent. of the deaths. This observation is on 50 monkeys, with post-mortems.

Other Animals.—Strauss quotes Koch and others as finding tuberculosis in white and brown rats, white and field mice. McEachren, chief veterinary inspector of Canada, says: "Rats, mice and other vermin not only contract tuberculosis, but spread the disease." Sibley reports a case in a serpent, tropidonotis natrix, an Italian snake, dying after a captivity of some months in a zoological garden. At the Berlin Congress the same author reported other cases in snakes—in grass snakes and common English vipers. In this connection I report the case of a python kept for several years in a glass case in the animal house, at a temperature never falling below 70 F., and showing tuberculosis post-mortem.

Despeignes has produced tuberculosis in frogs and tritons kept at room temperature. Lortet and Despeignes have demonstrated that tubercle bacilli can be transported and spread by earthworms.

Geographic Distribution.—Hirsch says that tuberculosis may be designated an ubiquitous disease in the strictest meaning of the term. Whatever reason there may have been for doubt as to the accuracy of this statement at the time of Hirsch has since been removed. The few places in which no tuberculosis had been reported in his day have since been found to furnish no exceptions to the general rule.

So far as I have been able to gather, in the larger cities of Europe, the death-rate from tuberculosis of all forms constitutes something more than one-fifth of the total death-rate. The death-rate is about 350 per year per 100,000. This is approximately true of every continental country.

Austria and Hungary will run a little higher than Holland and Switzerland. In the smaller towns and country the death-rate is about 260 per year per 100,000 inhabitants. In Great Britain the situation is somewhat better, the death-rate being in the vicinity of 225 per year per 100,000 inhabitants. According to Hirsch, Iceland, the Faroe Islands, the Hebrides and Shetland Islands have some, but not much, tuberculosis. According to data received from the government, the amount of tuberculosis in Iceland is about 150 cases per year. This, considering the open life of the people, the lack of crowding and the primitive conditions of life, together with the inaccuracy as to death-rate that must prevail amongst isolated folk, constitutes a considerable mortality. The northernmost parts of Norway and Russia appear to have but little tuberculosis, yet from all of these districts information must be meager. That it is to be found is certain. In the account of the Wellman Expedition there is reference to a polar bear killed on the ice and showing tuberculosis. Nansen records bacteria and bacterial diseases in the coldest latitudes. He had no opportunity to observe tuberculosis.

It is found in Armenia, Syria, Persia, Mesopotamia, Greece, Arabia, India, Turkey, Ceylon, the East Indies, China and Japan, the Philippines, Sumatra, in all the islands of the Southern Pacific and in Australia. In Africa information is necessarily insufficient, but that which we have is to the effect that the conditions there are much the same as elsewhere. Wherever, in the interior, lives are wild and houses are unknown, tuberculosis is present, but rare. On the coast, along the waterways, along the channels of communication, whereever civilization has touched, tuberculosis is rife. Generally speaking, the disease runs a rapid course. The housed native, whether he be Bedouin or Kaffir, suffers to the maximum extent. The formerly supposed immunity of Algiers, Morocco and those portions of the Mediterranean shore has not been sustained by fuller information.

When we come to America, we find the disease widely spread. A recent article in the *Century Magazine*, on the giant Indians of Terra del Fuego, mentions their great robustness, so long as they stay away from civilization, but their rapid extinction by tuberculosis whenever they approach the ways of the white man. In Argentina, Uruguay, Paraguay, Brazil, Chili, Peru, Ecuador, Bolivia and the countries of the Caribbean littoral, it is found much as in Africa. In the interior, in the scattered habitations of the higher elevations there is some tuberculosis, but not much. Along the channels of travel there is an increased amount. In Rio Janeiro and Pernambuco the death-rate is 350 and 520 per 100,000, respectively. In Mexico and all the countries of South America there is the same story—the disease rarely found in the sparsely settled interior, very virulent and very abundant in the more thickly settled littoral. In all the islands of the Caribbean Sea there is much. In Cuba it kills more people than do malaria and yellow fever combined. Canada has but little less than the more densely populated United States. T[illegible] the United States, according to [illegible] census c[illegible] 103,000 people died with tu[illegible] during [illegible] ceding year. It is the op[illegible] tistici[illegible] thority connected with the census office, William King, that this figure is 30 per cent. too low. This would make 143,000, or about 210 to each 100,000 inhabitants. It constitutes about one-ninth of the total death-rate. In the city of Chicago it constitutes one-eighth of the total death-rate.

I offer the following conclusions:

1. Every animal having tuberculosis is a center for the maintenance and spread of tuberculosis. We must admit great variance in danger, according to the animal affected. The danger from the cow, by reason of the fact that we drink milk unboiled, is great. The danger from the horse is much less. In spite of this variance the proposition commends itself. Each of the excretions may contain tubercle bacilli. These go either directly into man, there to run the gamut of his defense, or into the world, there to perish, as a usual proposition, but, sometimes, to persist and threaten men and other animals.

2. Animal, and even aviary, tuberculosis is not identical with, but is related to, human tuberculosis. The translation of human into animal and aviary tuberculosis is also possible. A great deal of accurate, painstaking work has been done on the question of the transformation of human into bovine and avian tuberculosis, and vice versa. I mention the work of Theobold Smith and that of Nocard. Theobold Smith's work seems to me to show that while there are structural and biologic differences between the bovine and the human bacillus, the differences are not of great pathologic importance. This is borne out by cases of infection of people by bovine bacilli and of cows by human bacilli. In a short search of the literature I have found cases cited by Strauss, Bang, Colin, Nocard, the Illinois Board of Stock Commissioners, Bray, Crosse of Geneva, Cadeac and Bourney. The observations of this nature are far too numerous for recital. Nocard's work showed that human tubercle bacilli could be transformed into the avian form.

3. Inhalation and ingestion are the most frequent means by which tuberculosis is spread from man to man, from man to animals, and from animals to man.

4. The geographic distribution of tuberculosis is proof that the organism's extracorporal or saphrophytic life is of secondary importance. Argument in support of this proposition is found at every step by the bacteriologist. If this bacillus is found regardless of temperature, of soil moisture, of total rainfall, of elevation from the sea level, of prevailing winds, then it must follow that its essentials are resident in the animal body, where environment is more uniform. Nuttall's observation that the number of tubercle bacilli expectorated in the twenty-four hours is about three billions, would prove that only an infinitesimal number live outside the bodies of animals. The lesser number of cases of tuberculosis at high altitudes, away from cities, in dry climates, etc., is due to the improved condition of the people and of their hygienic conditions, such as lack of crowding, well-ventilated habitations, out-of-doors life, vigorous existence, etc., rather than difference in bacilli or in the effect of extracorporal environment on bacilli. However, we can not altogether deny the power of sunshine and drying on the bacilli that lie exposed.

5. There is abundant evidence that the bacillus is modified by the bodies through which it passes. Such is the teaching of the work of Bang, of Smith, of Nocard, of Jones and many others.

6. While Proposition No. 5 is incontestable, there is no evidence that the disease will disappear by reason of a general immunity. In the contest waged between the system and this bacillus, the wandering cells and the chemical substances of the body play a lesser part than in almost any other of the infectious diseases. Protection is had by reason of the activity of the fixed tissue-cells of the body. In those diseases which are due to organisms violently poisonous to the human body, the reaction is sharp, the death or cure speedily results. The very mildness of tuberculosis is responsible for its ultimate severity. The fact that the system takes so little cognizance of it constitutes the difficulty. In consequence, immunity is less a factor than in any other infectious disease. By this, I mean special immunity. The general immunity that comes from great good health and resisting power must be allowed by all.

7. The decrease in the death-rate from tuberculosis is more apparent than real. I want to reassert my statement made in this section last year that, while fewer people seem to be dying of tuberculosis than formerly, the proportion between the death-rate from tuberculosis and that from other diseases is not decreasing. In this connection we must bear in mind the fallacy of taking, without great caution, statistics that antedate 1880. If we limit our comparisons to the period since 1890 we will not find any material decrease.

8. Tuberculosis is above all a disease of crowding, and therefore a disease of cities. The disposition of the age is toward city life, and therefore a slight decrease, or even no decrease, in tuberculosis constitutes a gain.

9. At some future date, in determining the question of favorable location in order that a man may escape tuberculosis himself, shield his family from it or get well, once the disease has been contracted, we must ask the following questions: *a*. What is the altitude? *b*. What is the percentage of sunshine and cloud? *c*. What is the soil moisture? *d*. What is the atmospheric moisture? *e*. What is the population per acre? *f*. What is the amount of tuberculosis present in men? *g*. What is the amount of tuberculosis in animals and birds? *h*. Is the mean temperature approximately that of the district from which the man is to go?

103 State Street.

TUBERCULOSIS IN PENNSYLVANIA.[*]

GUY HINSDALE, A.M., M.D.

President of the Pennsylvania Society for the Prevention of Tuberculosis; Secretary of the American Climatological Association: Fellow of the College of Physicians of Philadelphia, etc.

PHILADELPHIA.

Pennsylvanians are beginning to take more interest in the subject of tuberculosis. In a state in which about eight thousand persons, nearly all of them in the prime of life, die of this disease each year, it ought to receive much more attention from those who have it in their power to reduce this unnecessary sacrifice of life. The first and last systematic study of consumption in Pennsylvania was made by the late Dr. William Pepper and the writer in 1886 for the American Climatological Association and was published in the Transactions of that society. It developed the fact that there is a great inequality in the distribution of this disease throughout the state. There are seventy counties in Pennsylvania. Some of them are sparsely inhabited, are deeply wooded; the country is wild; the elevations range in the neighborhood of two thousand feet or over. The children "born and raised" in these counties have purer air to breathe, purer water and milk to drink, a better chance to develop their sturdy chests, for they drive the cows to pasture, trudge to school in cold weather and help on the farm in summer. Neither they nor their parents may realize it, but they are, from our standpoint, the favored class in the general population. They are the survivors of representatives of the hardy pioneers who developed the natural resources of Pennsylvania.

---

[*] Presented in a Symposium on Tuberculosis, to the Section on Hygiene and Sanitary Science, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

In twelve or thirteen counties, such as Pike, Sullivan, Montour, Union, McKean, Forest, Elk and Cameron, there is only about one-fourth as much pulmonary tuberculosis in proportion to the population as in some of the more populous counties. At the other extreme we have Philadelphia, Delaware and Lancaster counties. These lie in the southeastern corner of the state. The air is warmer and more moist; the country is less than five hundred feet above sea-level. The soil contains a considerable quantity of clay. The water-supply, for the cities at least, is from rivers that are contaminated, and the environment of the inhabitants of Philadelphia, Reading and Harrisburg is not conducive to the development of that bodily vigor that we find in the highlands of Pennsylvania. A glance at South street, Bainbridge or Fitzwater street, with poverty, vice and filth on every side, is explanation enough for the prevalence of tuberculosis. Children born and brought up amid such surroundings are an easy prey to any infectious disease.

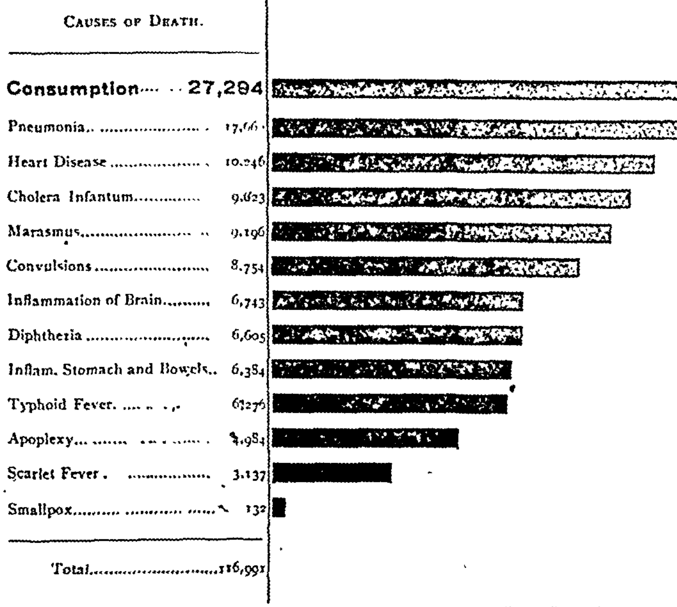

Diagram Showing Comparative Mortality by Deaths from Thirteen Prominent Causes of Death in Philadelphia, for the Ten Years, 1884-1893, inclusive.

In addition to moral and physical degeneration, the general lack of proper ventilation of city dwellings is a great predisposing agency in contracting consumption.

Atmospheric conditions in southeastern Pennsylvania favor the development of tuberculosis. The air is more humid, the rainfall is greater and the alternations of warm and cold weather throughout the winter and spring produce bronchitis and give rise to more colds than in the portion of the state where snow lies on the ground all through the winter and where the seasons are more sharply defined.

The prevalence of pulmonary tuberculosis compared with other diseases during a period of ten years is seen from the accompanying chart.

It will be noticed that the deaths from this disease in ten years exceed twenty-seven thousand, about equaling the combined deaths from diphtheria, typhoid fever, apoplexy, scarlet fever, smallpox and inflammation of the stomach and bowels. Between 1870 and 1897 there was a constant fall in the number of deaths from pulmonary tuberculosis in proportion to the population, but the proportion rose slightly in 1899. In fifteen years the percentage of deaths from pulmonary tuberculosis has fallen from 14 per cent. of all deaths to only 10 per cent. This has been a great gain. Just why the rise occurred in 1899 it is not possible to say precisely. It has been suggested that the better methods of diagnosis now in vogue show more cases to be tuberculous. Every hospital and outdoor clinic has its bacteriologic laboratory and the bureaus of health in Philadelphia and Pittsburg render valuable services to physicians unconnected with the hospitals. In 1899, 675 examinations of sputum were made by Dr. A. C. Abbott and Dr. Stetson in the laboratory of the board of health of Philadelphia. Cases which might have been returned as having died of bronchitis, for example, were doubtless thus found to be tubercular. This may account for the remarkable reduction of the number of deaths recorded from bronchitis; last year they numbered only 389, but in former years they were five or six times that number. In the first six months of 1900 there were 1434 deaths from pulmonary tuberculosis, while in 1899 for a corresponding period there were 1507. A reduction in the rate will no doubt continue.

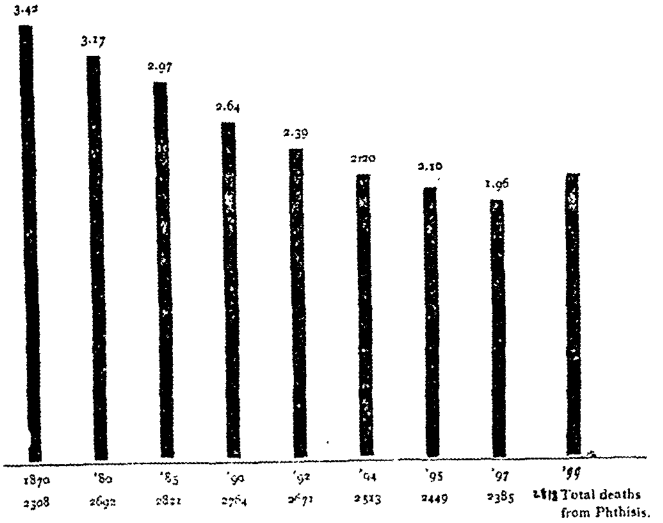

Chart Showing the Steady Reduction in Deaths per thousand of Population, Philadelphia, 1870-1899.

As physicians take advantage of the newer methods of diagnosis, including sputum examinations and X-rays, cases will be earlier recognized and cures accomplished in the incipient stage. The medical profession is justly entitled to claim more credit in this field than is usually accorded even by its own members. Physicians work harder and more hopefully in a given case of pulmonary disease than they did twenty-five years ago. Soundings are taken much oftener on the dangerous coast ar tie t so often to drift and go to pieces on the treacherous reefs without one word of warning.

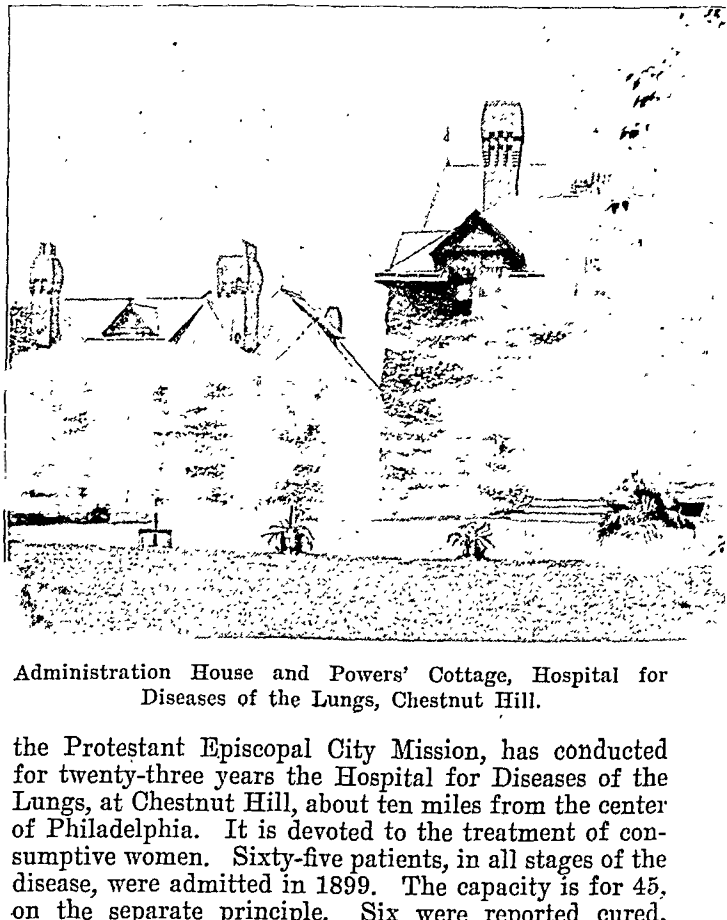
People are not so ignorant nowadays of the means of prevention of consumption and they have been educated not a little by physicians and by newspapers and special publications as to what should be done to limit the scourge. There may never be a time when there shall be no shipwrecks; there may never be a time when there shall be no consumption, but there is every prospect that some day deaths from this cause will be comparatively few.

The Pennsylvania Society for the Prevention of Tuberculosis was the first to be organized in this country, at least, with this particular end in view. It was organized on April 10, 1892, and incorporated in 1895. It has endeavored to educate the community in a knowledge of the true nature of consumption and the means now considered necessary to control or conquer this disease. The means by which this end is sought to be obtained are: by the publication and distribution of pamphlets; by constant efforts to induce those in influential positions to use their earnest efforts to prevent the spread of the disease; and by striving to obtain the requisite conditions whereby those early afflicted may be restored to usefulness, or for those far advanced, the safeguarding that will prevent the communication of infection to others. Between seventy-five and eighty thousand copies of tracts or pamphlets have been issued, principally for distribution in Pennsylvania. They have been forwarded, on request, to various states from Maine to Oregon and California, and even to Hawaii,[1] and have been reprinted, with slight changes, and circulated widely. No. 1 is entitled "How to Prevent Contracting Tuberculosis (consumption)." No. 2, "How those Suffering from Tuberculosis Can Avoid Giving it to Others." No. 3, "How Hotel-keepers Can Assist in Preventing the Spread of Tuberculosis." No. 4, "How Storekeepers and Manufacturers Can Help to Prevent the Spread of Tuberculosis." No. 5, "Predisposition to Disease." No. 3 has been translated into Hebrew for circulation among the Jewish population. These leaflets can be easily handed to those attending dispensaries and are always well received and additional copies are frequently asked for. This society will always furnish copies of its tracts free to those applying for them, or in large quantities at the cost of paper and printing.

A committee of the society has gone twice to Harrisburg, and has urged the committees on appropriations at two legislatures to provide for a hospital or sanitarium to be erected by the State of Pennsylvania in some mountain region suitable for this purpose. These measures have on both occasions been favorably recommended by the Board of Public Charities after full investigation and have been apparently well received by the committees on appropriations, much sympathy being shown by individual members. Other influences, however, including a false sense of economy and immense losses to the state through bank failures and dishonest officials have rendered our appeal futile. In the city of Philadelphia we have been confronted by a similar state of affairs. The apathy shown at home is in strong contrast with the enlightened and advanced attitude of foreign governments, which have established many institutions of their own and generously given aid to others. America is far behind England, Germany and France in this regard. While it is humiliating to acknowledge our deficiencies we must make them known in order to secure their correction by encouraging public-spirited men and women of our country to grapple with the herculean task.

The Pennsylvania Society for the Prevention of Tuberculosis requested the Board of Health to consider the advisability of issuing circulars or public notices, to be properly distributed, warning against the uncleanly, unnecessary and reprehensible practice of spitting in public places and conveyances. Such a circular was issued by the Board in 1895, and thousands of copies were widely distributed. Every one of the 1500 street cars in Philadelphia is provided with a conspicuous sign authorized by the Board of Health forbidding the practice of spitting on the floor. There is, however, no law in Pennsylvania under which any one can be arrested and punished for such an act on the streets or elsewhere, but the presence of the order of the Board has done a great deal to improve the appearance of the sidewalks and street cars.

In caring for the tuberculous three special corporations are devoted to this purpose. The oldest of these, the Protestant Episcopal City Mission, has conducted for twenty-three years the Hospital for Diseases of the Lungs, at Chestnut Hill, about ten miles from the center of Philadelphia. It is devoted to the treatment of consumptive women. Sixty-five patients, in all stages of the disease, were admitted in 1899. The capacity is for 45, on the separate principle. Six were reported cured, 18 improved, 9 unimproved and 36 died. A department for men, called the "House of Mercy," at 411 Spruce street, in the heart of the city, admitted 45 during the year. Since their organization these institutions have cared for about 2900 patients. Dr. J. Solis-Cohen, Dr. Wm. M. Angney, Dr. C. A. Currie, Dr. F. W. Thomas and Dr. Robert H. Bolling are the attending physicians.



Administration House and Powers' Cottage, Hospital for Diseases of the Lungs, Chestnut Hill.

The Rush Hospital for Consumption and Allied Diseases was opened in 1892, and in 1895 occupied a site at 33d Street and Lancaster Avenue, West Philadelphia. It has a capacity for forty patients in wards, but its means at present do not admit a provision for more than 20. It has received annually $5000 from the State of Pennsylvania since its organization. There are two free beds, a dispensary is attached and fulfils an important work.

---

[1] The number of deaths from pulmonary tuberculosis in Honolulu has more than doubled in the last five years.

The Free Hospital for Poor Consumptives was organized in 1895 and incorporated in 1897. Its object is to give hospital treatment to the consumptive poor. It has not yet procured its own home, because all the money it has been able to raise has been expended for the pressing needs of cases which have presented themselves; it pays their board in existing hospitals in Philadelphia and elsewhere. These include St. Agnes', St. Mary's, the German, the Rush, the Hospital of the University of Pennsylvania and the Sanitarium Gabriels in the Adirondack mountains. During the five years of its existence, the Free Hospital for Poor Consumptives has paid out over $20,000 in board for urgent cases. Over $6000 was thus expended in 1899, and 124 persons received hospital treatment. The fund is supported by contributions of small amounts, and there are 320 glass globes placed in drug stores, banks and other available places, yielding a bountiful supply from those who could not be easily reached, and anonymous donors who would be unlikely to make formal subscriptions.

Hospital for Diseases of the Lungs, Chestnut Hill, Philadelphia

Steps are being taken to secure a desirable out-of-town property for the needs of this charity. Its president, Dr. Lawrence F. Flick, has shown indefatigable energy in creating an interest in its work. The receipts for the charitable work of the Free Hospital are now over $10,000 a year. It affords prompt relief and has a record of not one case of consumption having been turned away.

These four organizations, expending their effort in three different fields, supplement each other's work for the restriction of consumption. The Pennsylvania Society for the Prevention of Tuberculosis directs public attention to the principles underlying the nature of the disease, the reasons why a fight against tuberculosis is perfectly rational and its extinction almost within our grasp. Its work is to teach, to encourage private and to urge public action. It will gladly co-operate in all possible ways to advance the interests of hospitals for consumption.

The Hospital for Diseases of the Lungs, at Chestnut Hill, and the Rush Hospital receive cases and treat them as they present themselves and as their very limited endowments render possible. The Hospital for Poor Consumptives co-operates with every hospital in Philadelphia that will receive such patients and pays their way in existing institutions. It makes its plea to the public for support on the ground that the disease being contagious, the lot of the consumptive in these latter days has been growing harder and the only protection the well have against infection is by the hospitalization of the consumptive population. Besides the idea of personal protection is the fundamental idea of unselfish charity, which is the principal motive of the organization.

The best method of dealing with tuberculosis in cattle is a much simpler proposition. The Pennsylvania State Live Stock and Sanitary Board in the last two years has examined and tested with tuberculin at the expense of the state over 34,000 cattle, and of these over 5000 have been condemned and destroyed. The law provides that farmers shall be reimbursed, in order that hardship may not result. They receive an average of $22.30 per head; or not over $50 for registered stock and not over $25 for unregistered stock; in this way nearly $150,000 has been expended. To carry out this important work nearly 60,000 doses of tuberculin have been administered by authority of the state veterinarian, Dr. Leonard Pearson, of the University of Pennsylvania. He has encouraged the state to advance the funds to carry on the work; he has interested veterinarians all through Pennsylvania in the extermination of tuberculosis among cattle, by furnishing them the means of testing herds and inducing farmers to exercise greater care in preventing the spread of the disease throughout their herds and from animals to man. For the systematic, intelligent, far-reaching work which Dr. Pearson directs, and for his activity in ensuring conformity to the laws governing the importation of cattle into the state and the sale of meat and milk, every man, woman and child in the commonwealth is under obligation.

Pennsylvania may justly be proud of this feature of the struggle against tuberculosis, in which she takes a firm and liberal stand, yielding the palm to none.

3943 Chestnut Street.

MUNICIPAL REGULATION OF THE SPITTING HABIT.*

ELMER B. BORLAND, M.D.
Professor of Hygiene and Dietetics, Medical Department, Western University of Pennsylvania.
PITTSBURG, PA.

Charles Dickens decided that, as a people, we lack the national instinct of cleanliness. He therefore designated Americans a nation of spitters. We no doubt deserve the designation, as the enlightened nations of Europe regard spitting on the floors and sidewalks as not only unsanitary, but an evidence of ill-breeding.

Five years ago the writer read a paper before the Allegheny County Medical Society recommending restriction and regulation of the spitting habit. Nine out of ten members who took part in the discussion agreed that restriction and regulation were needed. Six, however, of the nine thought any regulation impossible. "Women can, but men can not, change their filthy spitting habits."

---

* Presented in a Symposium on [illegible] osis, Section on Hygiene and Sanitary Science, [illegible] rst [illegible] eeting of the American Medical Associat[illegible] J., June 5-8, 1900.

The writer believed that most men had the natural instinct of cleanliness and could be educated in this respect up to the level with women; and further, that the ignorant, unteachable and vicious could be controlled by the absolute fiat.

The principal aim of this paper, however, is a brief review of what has been accomplished in this most important sanitary reform.

During the past year the writer has been in communication with the boards or bureaus of health of twenty-two principal cities of the United States. The following were the four principal questions asked:

1. Have you a special anti-spitting ordinance?
2. If you have not, do you attempt to restrict spitting under your general nuisance act?
3. Date of your special ordinance or order forbidding expectorating on public floors and sidewalks.
4. Result of enforcement.

An analysis of the replies gives the following information: Special laws have been enacted in one-half of these cities, and about one-fourth are regulating partly or wholly under their general nuisance acts. These ordinances empower bureaus of health to abate or prohibit anything of an unsanitary character; indiscriminate spitting is included.

In the past five years, New York and Brooklyn, Newark, Columbus, Cleveland, San Francisco, Pittsburg, Washington, D. C., Rochester, New Orleans, Louisville and Baltimore have enacted special laws.

Denver, Atlantic City, and one or two others, have special laws under consideration.

The Boards of Health of Chicago and St. Louis have contented themselves with suggestions to the public, mainly through signs placed in street cars.

The Boards of Health of Philadelphia and Boston are doing good work under their general nuisance acts.

The Bureaus of Health of Detroit, Buffalo and St. Augustine are not in the working line. Hopes may be entertained for the two former, but, alas, St. Augustine! Poor St. Augustine! This ancient landmark answered the writer's inquiries thus: "Our native people would consider such an order an insult to their dignity. Can not stop a Florida cracker from spitting." May we interpret from this answer that these people love darkness rather than light?

Many superintendents of bureaus of health do not seem to realize that they can regulate spitting under their general nuisance act. Others do not have backbone enough to promulgate and enforce an order. Special ordinances, however, attract the attention of the general public and are probably more easily enforced.

New York and Brooklyn are under one law, with a maximum fine of $500, or one year's imprisonment. Newark has one of the best special laws yet enacted. It has been tested and sustained by the court. The offender was convicted and the fine imposed. The ordinance is as follows:

> Whereas, expectorating in street railway cars or other public conveyances, or in any public building, is deemed by the board of health of the City of Newark to be prejudicial to the health of its citizens: Therefore, be it ordained by the board of health of the City of Newark as follows:
>
> Section 1. No person shall expectorate upon the floor or any part of the interior of any street railway car or other public conveyance or any public building in the City of Newark.
>
> Section 2. Any person who shall violate the provisions of this ordinance shall be fined for the first offense ten dollars ($10) and for the second and any subsequent offense twenty-five dollars ($25).
>
> Section 3. Officials in charge and control of street railway cars or other public conveyances, or of any public buildings, shall post and keep posted in a conspicuous place one or more printed notices of the provisions of this ordinance prohibiting expectoration, and the conductor or conductors of any such cars or other public conveyances, and the janitor or persons in charge of any public building, shall call the attention of all violators of this ordinance to such notice, and shall report any violations thereof, with a description of the persons offending against this ordinance, immediately to the board of health of said city, and any such person failing to post the notices required by this section, and to make the report herein provided for, for failure so to do shall forfeit and pay a fine of five dollars ($5.)
>
> Section 4. This ordinance shall take effect immediately.

Boston operates under her general nuisance ordinance, with a maximum fine of $100. The following is the text of this brief but concise order, issued by the Board of Health, in 1896, and revised in 1899.

> The board of health hereby adjudges that the deposit of sputum in public places is a nuisance, source of filth, and cause of sickness, and hereby orders: That spitting upon the floor, platform or steps of any railroad or railway station, car, public building, hall, church, theater, market, or any sidewalk immediately connected with such public places, be, and hereby is, prohibited.

In reply to the writer's special inquiry, the president reports: "The result of the enforcement is a most remarkable change from filth to cleanliness."

The courts of Newark and San Francisco have sustained their anti-spitting laws. The offenders were convicted and the penalties imposed. A millionaire was convicted by the superior court and the judgment sustained by the supreme court of California. He paid his fine of $25 and served one day in jail. Attorneys interested can secure data of the above cases by writing to the clerk of courts in either of the above-named cities.

The decision of the supreme court of California has established the fact that the passage of anti-spitting laws is a proper exercise of police power of the city. The entire Board of Health of San Francisco is composed of physicians, which probably accounts for the efficient work recently accomplished.

Men without scientific training or special fitness are frequently placed—by corrupt politicians—in charge of bureaus of health. The annual reports of these men often read like the minutes of a mutual admiration society, and their work is about as valuable. These reports and the inefficient work are sufficient evidence of the need of placing a medical executive board over all bureaus of health.

Public opinion is being rapidly educated, and if bureaus of health are inefficient, and anti-spitting laws are not well enforced in the near future, the question of first and second class electric and steam railway cars, to separate clean from indifferent people, will probably demand consideration, even in this democratic land. If rapid-transit street-car companies do not give this factor of car sanitation the attention it deserves, private motor carriages will crowd the streets, and this will delay and lessen street-car travel.

All communities have a few so-called scientific men, a few men in power, a few car conductors, a few "don't cares," who would rather wallow in public expectoration than set an example of cleanliness to the general public. There are also a few persons who consider it their sacred duty to clog the wheels of preventive medicine by opposing every useful reform and wailing over every offensive and dangerous institution as it falls.

Much has been done toward educating teachable people. The work is well begun. The pessimists of a few years ago are the astonished optimists of to-day. Thousands of earnest workers are now in the field where not a corporal's guard stood when the writer began agitating this factor of public health five years ago.

HEREDITARY FACTORS IN TUBERCULOSIS.*

J. M. ANDERS, M.D., LL.D.
Professor of Medicine, Medico-Chirurgical College.
PHILADELPHIA.

The hereditary factors are regarded as being less influential at the present day than was held prior to Koch's important discovery of the tubercle bacillus. It has been conclusively shown that direct hereditary transmission is an exceptional occurrence. Hauser, in an extensive and careful review of all previous work upon this question, reached the conclusion that there are only 18 authentic instances of direct inheritance of this disease to be found in the literature. In all of these cases only the mother had tuberculosis. He contends that conclusive proof of direct transmision from the father is wanting and this position is probably the correct one. Hauser attempted to produce experimental direct hereditary transmision in guinea-pigs and rabbits, and in a single animal only was he successful, and this had been kept alive for months after birth. He decided that the theory of direct inheritance rests on insufficient evidence.

Birch Hirschfeld found that even though the fetus itself may show no evidence of tuberculosis, the fetal viscera may yet be infective to guinea-pigs. Baumgarten also believes that the contagion may be transmitted and become pathogenic at a variable period after birth. To support this view is the fact that certain structures not apt to be accidentally infected are commonly the seat of tuberculous lesions in children, as the bones and joints. Kuss disputes the theory of latency of tubercle bacilli until childhood or later in life. He contends that these latent foci do not exist before the age of three months; and that they are rare before the end of the first year of life.

Whilst it must be conceded that intrauterine infection is the exception, and although there is practically no hereditary tuberculosis there is a hereditary predisposition, which invites infection. In what does this predisposition consist? This is a pertinent question. Otis, of Boston, contends that heredity means poor vitality from birth and that subjects who manifest the same conditions without the influence of heredity are to a like extent predisposed.

It is well known that as the result of an unfavorable environment a predisposition to tuberculosis may be acquired. Hence, there is danger of confounding this condition of the system with inherited predisposition. Again, the latter form of predisposition is constantly being confounded with latent forms of tuberculosis, whether acquired or inherited. Although there is no harmonious agreement concerning its use and value, I feel convinced that we possess in tuberculin an agent by means of which existing latent tuberculosis can be reliably discriminated from mere predisposition. The question of dosage is vitally important. I have a fixed belief that greater uniformity of results of Koch's method would follow, if medium-sized initial doses—from 2 to 5 milligrams—were employed. As elsewhere stated, this would obviate the necessity of repeated injection, as is generally the case when small commencing doses—from half a milligram to a milligram—are used. Accurate results in most reactive cases could be expected, and an increased dose, if the repetition were actually demanded, would be unattended by any risk for the patient.

But even after eliminating in this manner, latent and obscure forms of tuberculosis, I know of no way in which to estimate with precision the percentage of cases in which the predisposition is inherited. That the proportion of cases is smaller than had been held prior to the important discovery of the bacillus tuberculosis is unquestionably true. On the other hand, my personal experience and observation is entirely confirmatory of the fact that individuals belonging to a family in which tuberculosis is distinctly traceable are more prone to the disease than similar constitutions or persons who have no tuberculous family history. This is even more true of the cases of phthisis that occur in individuals possessing a robust build. Indeed, I fear that in consequence of the modification of professional opinion in recent times relative to the question of heredity, there is danger that too little attention is now and will be in future given to the question of family history. In support of this position, I may be allowed to quote Allbutt, who forcibly remarks, "every physician engaged in practice among the classes in which family history can be acquired is morally convinced of the bias of many families to tuberculosis, however their circumstances may appear; a bias often revealed at the attainment of a certain age." Dock and Chadbourne in a statistical study of this subject also conclude that multiple appearance is commoner in families with tuberculous parents.

After making due allowances for all modifying circumstances, particularly accidental infection, including especially infected homes and prolonged contact with tuberculous subjects, I entertain no doubt that a predisposition to this affection may be inherited, and this tendency is more unfailingly transmitted through the mother than the father. It is analogous to the heightened receptivity or susceptibility that is observed throughout successive generations in certain families to typhoid fever or acute articular rheumatism. Finally, this increased susceptibility, which we [illegible] in a limited number of families, is dependent on a lack of resistance of the animal-cell and the latter [illegible] in turn [illegible] a faulty metabolism or nutrition.

TUBERCULOSIS AND INSURANCE.*

E. FLETCHER INGALS, M.D.
CHICAGO.

This subject, in order to be [illegible] be considered from two [illegible] diametrically opposed to each other and [illegible] therefore, hardly be [illegible] The two sides of the [illegible] benevolent features. [illegible] several policies in [illegible] I [illegible] more interested in the [illegible] highly appreciate the [illegible] widows and orphans [illegible] might say a [illegible] trusts, nevertheless [illegible] the rule, "[illegible] therefore that [illegible] pany itself, [illegible] who are insured in mutual companies, is really what will be the greatest good to the greatest number.

* Presented [illegible] on Hygiene and Sanitary Science, at the [illegible] of the American Medical Association, held [illegible] June 5-8, 1900.

Statistics from the mortuary tables of several of the largest companies in this country show that fifty years ago over 20 per cent. of the deaths were the result of tuberculosis. Until Koch's discovery very few cases besides those of pulmonary consumption were recognized as tuberculous diseases; therefore, it seems probable that nearly half the deaths of persons insured fifty years ago were from tuberculosis; but whatever the number may have been, business methods certainly require exercise of the greatest care to exclude undesirable risks.

I have been told by officials of life insurance companies that medical examinations appear to reduce their death-rates only during the first six years of the life of policies; but a large percentage of policies lapse or are surrendered during the first six years. These facts emphasize the necessity for the most thorough medical examinations if an insurance company is to do a safe business. The points which appear of greatest importance in this examination and to which the examiner should give greatest attention are:

1. Weight, which in a general way determines the state of the nutritive functions better than anything else. The abnormally light body in a large percentage of cases is the one that will sooner or later become tubercular.

2. Poor digestion. This often causes the light weight and indicates feeble resisting power, which makes the individual peculiarly vulnerable to tuberculosis. In many these two symptoms indicate that the tuberculous process is already established.

3. Pulse. Although there are many healthy persons in whom the pulse is easily accelerated and although it is above 80, while standing, in the majority of men brought in for life insurance examination, yet a persistently fast pulse of 100 to 120 must be looked on as one of the most frequent symptoms of tuberculosis.

4. Frequent attacks of bronchitis. It appears to me very doubtful or even improbable that catarrhal bronchitis often leads to pulmonary tuberculosis, yet if we accept the statements of applicants we must not forget that these so-called attacks are often only exacerbations of the symptoms of pulmonary tuberculosis.

5. Frequent pneumonia. Repeated attacks of pneumonia must leave the lung in a crippled condition, which, other things being equal, would favor the development of pulmonary tuberculosis; yet recovery from pneumonia may in some instances be considered a most favorable prognostic, indicating that the individual is immune to tuberculosis.

6. Repeated attacks of pleurisy appear to be usually of tuberculous origin.

7. Heredity. It is a rule with some of the best companies to reject all risks where a parent and one brother or sister have died of consumption, unless the applicant has passed the age of 35. I believe this a prudent precaution, essential to the welfare of all policy holders in mutual companies. In recent years many physicians of large experience have come to doubt the importance of this factor, and it has not been difficult to find statistics to support their contention, because in nearly all statistics the most important factor is ignored or can not be found. The missing factor is: How many cases would have occurred without hereditary predisposition?

The fact that the Brompton Hospital reports show that one parent has had phthisis in nearly 25 per cent. of the cases of consumption does not by any means show that neither parent has suffered from phthisis in the other 75 per cent., nor yet that there would not have been an equal number of deaths from this disease if neither parent had suffered from it. The same may be said of Fuller's statistics, which show that when parents, grandparents and uncles and aunts are considered, 59.5 per cent. of the antecedents have had pulmonary tuberculosis. Williams' figures show that out of 484 cases of phthisis in which some of the relations had died of the disease, in 224, or over 46 per cent., the relationship was that of brother or sister. If these could be added to the above figures, probably not far from 80 per cent. of all cases would show hereditary predisposition, which is the whole percentage of the human race that are now believed to have tuberculosis at one time or another in some form.

When we take into consideration the missing factor we must admit that even these overwhelming figures prove nothing; and in fairness we must allow for common environment and contagion, the first of which might explain in some cases the occurrence of two or more cases of consumption in one family. Osler states that in 427 cases in the Johns Hopkins Hospital, 25, or nearly 6 per cent., occurred in married people where the husband and wife had suffered from the same disease. This is grasped by some as proof of contagion, but there is no accompanying proof that the relatives of these persons did not have tuberculosis in some form.

Direct transmission of the bacilli from mother to offspring has now been proved in several cases, though this must be very infrequent. Every one is familiar with the marvelous influence of heredity in perpetuating mental as well as physical peculiarities, or predisposition or immunity to some other disease, such as croup, measles, scarlet fever, smallpox, etc., numerous interesting examples of which might be given; then why should we question the transmission of that peculiarity which renders some susceptible to tuberculosis and enables others to withstand all the attacks of the bacilli and their toxins?

The records of the Paris morgue and several laboratory observations have shown that in healthy bodies, of those dying from accident, suicide or acute disease, tubercle bacilli may be found in a large percentage; or scars from previous tubercular foci are present. In 125 autopsies in the Foundlings' Hospital of New York, tubercle bacilli were found in the bronchial glands in every case. These various facts render it probable that all of us harbor the tubercle bacilli at some time, but if we inherit strong constitutions and avoid vicious environment we need not die of tuberculosis.

As examples of hereditary influence that can not be explained by the theory of contagion or similar environment, I may briefly mention two families among by personal friends. In a family with 12 adult brothers and sisters, the father had light eyes and the mother, who died of consumption, had dark eyes; three of the dark-eyed children, after they had left the parental roof and had homes of their own, died of pulmonary tuberculosis, though not subject to contagion and although living under entirely different environment. Another dark-eyed sister lost two dark-eyed children after they were grown, though her light-eyed son, who was constantly with his brother and sister, escaped. In the other family, the father when a young man suffered from consumption but recovered. His four children after arriving at adult life died of consumption, though under very different environment.

8. Hemoptysis. Cases of hemoptysis without other evidence of tuberculosis, or at least cases of hemoptysis

that have not been followed by recognizable tuberculosis, are fairly numerous, yet those who have had much to do with pulmonary consumption must admit that in the great majority of cases hemorrhage from the lungs or air-passages result from this cause; therefore, the rule that no applicant for insurance who has had hemoptysis should be accepted, until ten years have elapsed after the last hemorrhage, seems strictly just from a business standpoint.

9. Temperature. Daily elevation of temperature of from 2 to 3 F. is a very frequent sign of tuberculosis, but we must not forget that a daily elevation of 1 to 1½ F., sometimes extending over several months, is common under a great variety of conditions, which are not followed by any evidence of tuberculosis, as, for example, in simple catarrhal inflammation.

10. Physical signs of loss of elasticity, or pulmonary consolidation. It seems needless to emphasize the importance of rigid examinations under favorable surroundings, and this necessity ought to impress on the companies the paramount importance of having applicants examined at the examiner's office, instead of elsewhere. Considering the great importance of careful selection, I am surprised that some companies, from false ideas of economy, pay fees that are wholly inadequate for competent and careful service. No matter how well disposed an examiner may be, he will not give any considerable part of his services in these cases gratuitously, and the company will obtain from him only the amount of skill and care that it pays for. Statistics from one of the large companies show that, by careful selection on the lines I have just enumerated, it has progressively reduced its death-rate from consumption from 20.8 per cent. in a thousand 50 years ago, to 5.5 per cent. in the last five thousand deaths among its insured.

Recurring to the question: Are there any conditions under which the tuberculous may be insured, with any kind of policy and at practicable rates? I may answer that most companies accept certain risks that are in all probability tuberculous, providing the heredity, the previous history, and the environment make it appear probable that the individual will live long enough to pay the cost of the particular kind of policy that is issued. These policies must be credited partly to benevolence, though with the safe company the business interest demands very good judgment and a high premium in such cases. There are many more cases that might be safely accepted for limited periods; but the insurance company must always estimate the possibility of error or undue sympathy on the part of the examiner; therefore, it can not take any chances. There are also certain companies that make a specialty of extra hazardous risks at proportionate premiums. These policies are sometimes most beneficent, but usually the rates are prohibitory.

UNITED STATES GENERAL HOSPITAL FOR TUBERCLOSIS AT FORT BAYARD, N. M.*

MAJ. D. M. APPEL, SURGEON, U. S. A.

An order issued by the War Department, August 28, 1899, authorized the surgeon-general to establish a general hospital at Fort Bayard, N. M., as a sanitarium for the treatment of officers and enlisted men of the army suffering from pulmonary tuberculosis, and also to provide therein for the care and treatment of discharged soldiers entitled to the benefits of the U. S. Soldiers' Home, at Washington, D. C. Under the latter clause patients are enabled to remain under treatment indefinitely, even after their discharge from the army by reason of their physical disability or from expiration of their term of enlistment.

Fort Bayard was selected by the surgeon-general not only for its admirably suited climate but also because it was immediately available, its abandonment as a military post having been contemplated for some years, and, excepting for its isolation and difficulty of access, no better locality could have been chosen.

It is located in the arid mountainous region of Southern New Mexico, three miles from Bayard Station and ten miles from Silver City, both of which are on branches of the Santa Fé R. R. Having an altitude of 6040 feet, the climate permits of comfortable outdoor life during the entire year, and, excepting for the frequent high winds during the spring, is undoubtedly ideal.

When ordered to assume charge of the hospital I was directed to select and ship supplies as promptly as possible, to provide acommodations at once for a number of cases to be immediately transferred from the Soldiers' Home.

On my arrival, October 3, 1899, I found all the buildings, as well as the water and sewer systems, very much dilapidated, and extensive repairs and alterations, which were commenced at once, are still in progress.

The old post-hospital is now occupied as an infirmary for bedridden cases, including not only those in whom the disease is far advanced, but also the febrile cases, which are kept absolutely at rest until the subsidence of the fever.

The ambulant cases are obliged to remain outdoors at least eight hours daily during the entire year; they are not allowed to occupy their dormitories from 8 a.m. until 8 p.m., and the windows of the dormitories are always open. For those with severe cough, rooms with two beds are provided; the others are placed in rooms containing six and twelve beds and the convalescents are separated from those who still expectorate tubercle bacilli. All the patients are required to carry paper spit-cups, which must not be used longer than twenty-four hours and are then burned, and the orders against expectorating elsewhere are rigidly enforced. The alvine discharges of infirmary cases with intestinal tuberculosis are destroyed in a crematory.

Recognizing that the problem in the treatment of tuberculosis is essentially one of nutrition, no efforts are spared to provide abundant good and nutritious food. All the patients are weighed weekly, and the comparative report of such weights is regarded as an index of their general progress.

From Oct. 4, till Aug. 6, 1900, 165 patients were admitted, with results as follows:

	Discharged.	Remaining.
Not improved	14	21
Improved	20	54
Convalescent	11	26
Cured	4	1
	49	102
Died	14	

Cases are recorded as *cured,* when, after all symptoms have disappeared, they fail to react to the tuberculin test. Those in whom no tubercle bacilli are found after repeated examinations and all active symptoms have disappeared, but they still react to the tuberculin test, are classed as *convalescent.*

Though we have not yet completed our first year, our experience thus far tends to disprove the general op that altitude is contraindicated in laryngeal and hemorrhagic cases. In several cases admitted with laryngeal ulceration, the ulcers have healed, and in two cases who succumbed to their pulmonary involvement, and who on admission had extensive laryngeal disease, the larynx was found, post-mortem, completely cicatrized.

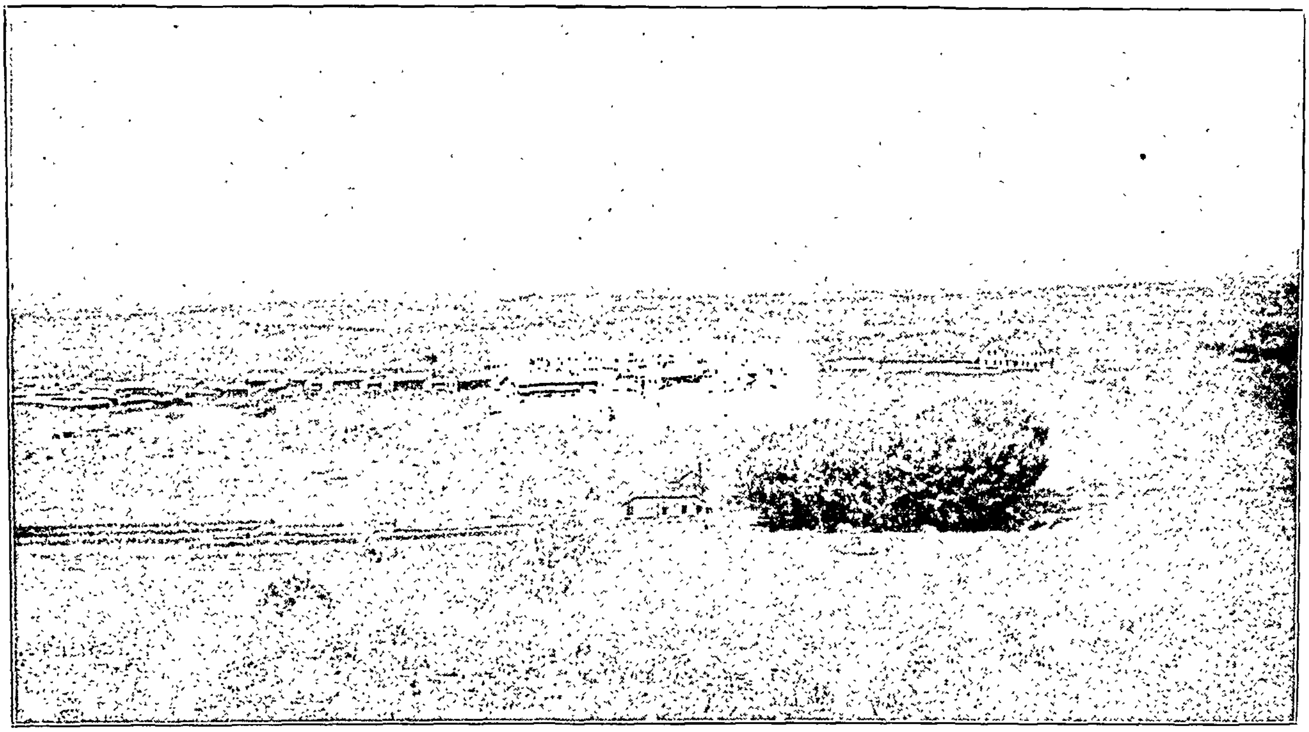
---

* Presented in a Symposium on Tuberculosis, to the Section on Hygiene and Sanitary Science, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

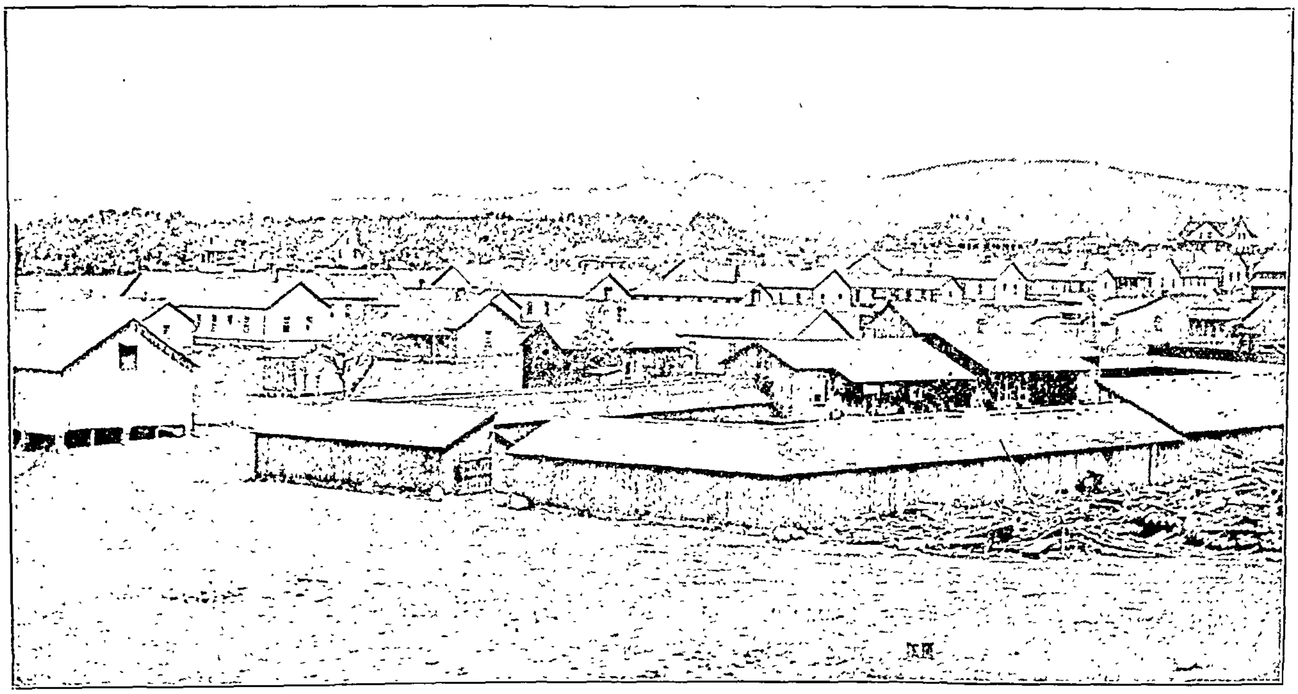
In quite a number of cases with a history of pulmonary hemorrhage before admission there has been no recurrence and in none has it been a serious feature.

Hectic fever is exceptional and usually subsides after a few weeks of complete rest. Night sweats are infrequent, and even in most advanced cases are readily controlled.

Many of those discharged "improved" and "convalescent" were no longer able to resist the pangs of nostalgia so prone to occur among the uneducated—which includes a majority of our cases—and which here is a result of the isolated location of the hospital and enhanced by the aridity of the vicinity. Others when discharged from the army are unwilling longer to submit to the necessary restrictions of the rules and regulations of an institution of this kind.



The majority of those discharged "unimproved" were advanced cases who preferred to return to their friends when told there was no reasonable hope of recovery.



The staff of the hospital consists of Acting Asst.-Surgeon James H. Hepburn and Acting Asst.-Surgeon E. S. Bullock, pathologist; Chaplain S. N. Pilchard, and Capt. H. McL. Powell, 14th Infantry, quartermaster and commissary.

There at present on duty seven female nurses, two of whom are employed as dietists, one hospital steward, two acting stewards, and sixteen privates of the hospital corps. In addition, a number of civilians are employed as cooks, baker, dairyman, watchman, teamsters and laborers.

I trust that after the hospital has been in existence for a sufficient length of time it will furnish interesting and perhaps instructive results.

THE ADVANTAGES OF THE SANITARIUM TREATMENT OF TUBERCULOSIS WHEN CHANGE OF CLIMATE IS NOT POSSIBLE.*

E. S. OLIVER (Johns Hopkins.)
SARANAC LAKE, N. Y.

The writer has for two years past been living at Saranac Lake, N. Y., as a patient and physician, studying the problem of tuberculosis in his own person, in the Saranac laboratory for the study of tuberculosis, and as a member of the staff of the Adirondack Cottage Sanitarium. The views he is about to express are the results of two years' study and observation, and are to be regarded solely as the expression of his own opinion and not in any sense to represent officially the institution with which he is connected.

As may be inferred from the title, it is accepted as a foregone conclusion that sanitarium treatment is the only solution of the many problems presented in this protean disease. The conclusion reached by the Berlin Congress and International Medical Congress in Paris leaves no room to doubt that the sanitarium treatment accomplishes what no "specific"—whether serums or drugs—can alone accomplish, and is capable of achieving, unassisted, all the beneficial results that can be claimed for either serum or drugs. Let us examine for a moment what may be regarded as the essential principle of the sanitarium treatment. First, unquestionably, comes the giving up of former habits of life, and the change from the old surroundings combined with the change to a more favorable climate. We, in Saranac Lake, are convinced that there is much of healing in the climate alone, and those of us who have suffered personally from the asthmatic breathing that so affects the tuberculous patient can testify to the vast difference in the quality of the air in the Adirondacks, as compared with that at our homes, and many of us go so far as to detect fine shades of difference between the air at Paul Smith's, that at Lake Placid—nay, even that at the Sanitarium, as compared with that at the village one mile away and 300 feet lower. We may as well admit that there is nothing essential in the altitude to which the patient resorts. The isolation of the patient from his family and community is of the utmost importance in combating the spread of disease. On the other hand, the segregation of persons more or less affected with the disease, especially of those in the same stage of progression, does away with the sensation of being an object of repulsion and danger—of being an outcast—which overwhelms the modern leper so long as he is in the company of sound and healthy individuals. This association with other patients supplies to him the social intercourse for which he longs in his enforced isolation and serves to combat homesickness, the pangs of which lead many hopeful cases to throw away their chance of recovery—for the mere sake of seeing familiar faces and hearing familiar voices. The sanitary precautions insisted on in the Sanitarium completely removes the danger of further infection and makes association with those recognizedly consumptive fraught with less risk than the average individual encounters in the street cars and stores which are the scenes of his daily labors. Moreover, the education which the sanitarium imparts as to the dangers of carelessness in disposing of the sputum is full of object lessons in themselves sufficiently valuable to justify the maintenance of such institutions. But it is the regulated out-of-door life amidst hygienic surroundings, with diet selected according to the individual's needs as carefully as his medicines are prescribed for his symptoms, and in the application of the best tried and most rational methods of medical treatment, that we find the vital essence of the sanitarium treatment.

The question of exercise is one on which Dr. E. L. Trudeau takes perhaps the most advanced position of all those who have successfully treated tuberculosis by the hygienic method. Exercise further than that necessary to go and return three times a day from the patient's cottage to the central dining hall is forbidden in the Adirondack Sanitarium to all those patients who reach a maximum temperature daily of 99.4 F. (37.5 C.). In cases maintaining for a considerable period a temperature of 100.5 F. all exercise is forbidden, and the patient remains at his cottage, lying in his cot on the veranda, where his meals are served by an orderly, from a diet selected according to the prescription of the physician in charge.

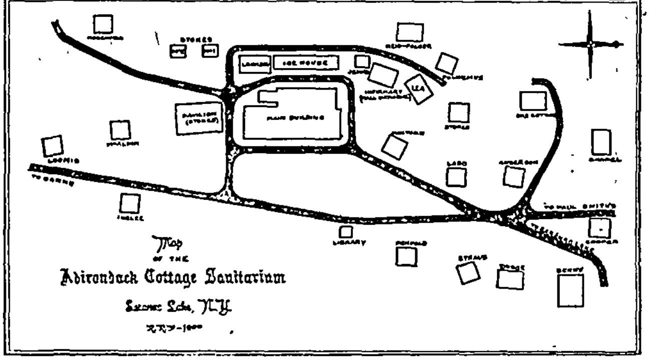


Figure 1.

RESULTS OF SANITARIUM TREATMENT.

To an observer who has studied tuberculosis in the wards of the public hospitals and sees for the first time the patients in the Adirondack Sanitarium, the first impression is one of absolute skepticism that these people, who present all the features of robust health, can be suffering from the dread destroyer with which he became familiar in his student days. The visitor finds that he is almost the only one on the grounds who coughs. He is conscious that he looks anemic and emaciated by the side of the consumptive, and he is apt to hurry away lest some other visitor will take him for the consumptive; nor is he unwilling after his visit to believe that of all patients, including those entering the sanitarium in all stages of the disease and remaining at least nine months under treatment, 34.5 per cent. go away apparently cured, while of those actually in the incipient stage 73.4 per cent. are apparently cured.[1] Not only the apparently cured, but many of those in whom the disease is merely "arrested," have been able to return to their vocations and live a practically normal life for a period ranging from one to fifteen years. To give a concrete idea of the results from our practical everyday experience among the Sanitarium patients, let me cite the instance of two patients whom I have just encountered on the street and asked for the record of their weights.

---

* Presented in a Symposium on Tuberculosis, to the Section on Hygiene and Sanitary Science, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Vide the excellent paper entitled: The Result of Sanatoria and Social Hospital Treatment in Pulmonary Tuberculosis, by H. McL. Kinghorn, M.D., Saranac Lake, printetd in the Montreal Medical Journal, July, 1899.

W. H. B. entered Sanitarium June 30, weighing 134 pounds; July 7, weighed 139 pounds; July 14, weighed 146 pounds; July 21, weighed, 149 pounds; July 28, weighed 153 pounds; August 11, weighed 158 pounds; August 18, weighed 161 pounds; August 25, weighed 164½ pounds.

H. P. D. entered the Sanitarium June 23, weighing 130 pounds; July 14, weighed 138 pounds; July 28, weighed 146 pounds; August 11, weighed 151 pounds; August 25, weighed 154 pounds.

A study of the official weight-book will show a score of such phenomenal gains in weights.

The accompanying charts taken at random furnish the most convincing evidence that pyrexia can most successfully be treated simply by the rigid observance of rest and outdoor life.

Cough as a symptom has much more significance for the patient than for the physician. I have repeatedly seen patients enter the sanitarium with a cough that kept them in paroxysms night and day, who could not walk from their cottage to the dining hall without pausing three times to expectorate in the receptacles provided on the ground. I have seen them lose their cough in a week or ten days, save for a single more or less violent paroxysm on retiring and on rising, and have heard them report the expectoration diminished in three weeks from three or four ounces on admission to half an ounce daily, when they were subjected to no treatment other than the hygienic routine of outdoor life in all sorts of weather.

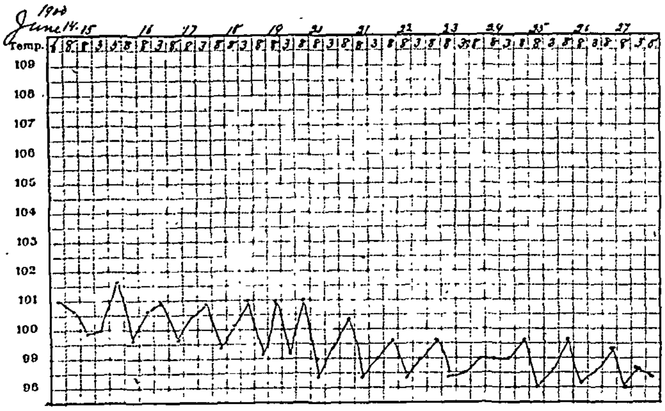

Figure 2.

The amount of food consumed at table three times daily by the patients, and between meals when so prescribed, is such as would surprise the hardest-working day-laborer of your acquaintance and give you reason to fear that some acute dilatation of the stomach must inevitably follow, until you had become accustomed to the appetite whetted by the tonic breezes of the Adirondack region.

As Dr. Trudeau has shown in the all too few articles he has written for the instruction of the profession, the early diagnosis is the cardinal factor in the cure of the disease, and not alone in the cure, but in the sanitary prevention of its extension. Early diagnosis becomes thus the keystone in the arch on which we are to build the structure of our barrier against the "white plague."

The average family practitioner recognizes the disease only when the symptoms are so prominent and the physical signs so unmistakable that the patient is already too far gone to stay his downward course.

The plan I propose is that where a general practitioner, or a specialist in pulmonary disease, has under observation and advice two or more cases really incipient, he should have sent them to a cottage, rented or built for the purpose, in some favorable situation in the suburbs of his city or town, say ten miles from its limits, where the air is uncontaminated by dust or smoke and the surroundings rural and attractive; a trained nurse should put the patients through, under the physician's close supervision, the regular sanitarium life as it is pursued in the Adirondack Cottage Sanitarium and the Muskoka Sanitarium on this continent, and in similar institutions in Europe, notably in Brehmer's Sanitarium at Gerbersdorf, in Detweiler's at Falkenstein, and in Walther's at Nordrach.

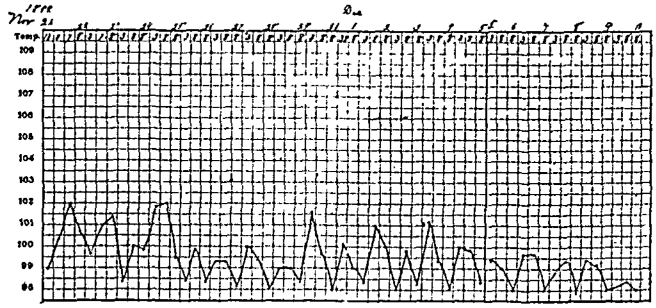

Figure 3.

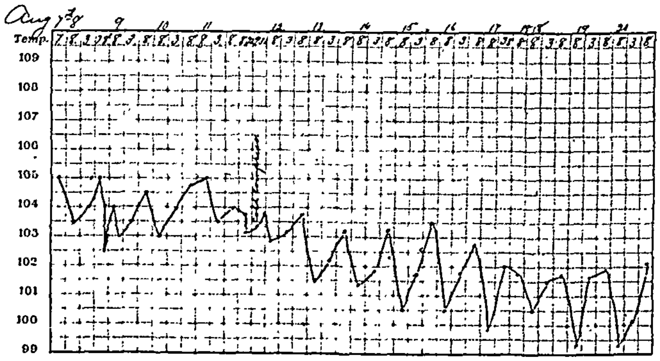

Figure 4.

In choosing a site for the miniature sanitarium, let a slight elevation be selected for the cottage, the exposure of the main verandas and bedrooms for patients to be on the south. The chosen location should be far removed from the din and bustle of the town, but near enough to some railway or tramway to give to the patient's family and business associates the opportunity of calling on him at such times as may be prescribed by the physician. If the roads in the neighborhood are suitable for driving, great pleasure and a considerable aid in the treatment is provided for. Of how little real moment the change of climate is, provided a rigid sanitarium treatment is pursued, is shown by the cures achieved in the Hôpital Boncecaut, located within gunshot of the fortifications surrounding Paris. Often a cottage may be found already built which may be adapted to the treatment proposed, but probably it will in most instances be found advisable to build a structure especially contrived to meet the needs of so unique a routine of daily life.

I append to this paper plans for such a building, drawn by a competent architect, Mr. W. H. Scopes, of

Saranac Lake, which will be found to embrace all the essential features of the sanitarium on the "cottage plan" rendered famous by Dr. Trudeau's work. It provides for a cellar, with plants for hot water, heat, coal-bins, pantries, and water closet for servants. The first floor (Fig. 7) offers a general sitting-room, dining-room, kitchen, bathroom with all the necessary appliances, two bedrooms, the nurse's bedroom and her office and consulting-room. Open fireplaces are provided, both for the sake of ventilation and for their cheerfulness.

The second-floor plan (Fig. 8) shows a scheme for four additional bedrooms for patients, and in the third floor, as shown by the side elevation, are rooms for the cook and chambermaid (Fig. 9).

The covered veranda around the southern and western sides on the first floor, and the open veranda on the second-floor, offer the best possible opportunities for that life of repose in the open air which is the essential point in the treatment, according to the open air plan. Lounges, reclining chairs, hammocks or camp beds are furnished to suit the tastes of the patients. The rooms should be wainscoated to a height of six feet and finished in plaster, and "moresco" for the rest of the walls and ceiling. The floors are best made of hardwood, oiled and polished, or else covered with linoleum, with a rug or two of some washable stuff. Electric light is the only form of artificial lighting permissible. The windows should be of ample size, and of the fashion that permits them to be raised and lowered, and in the same frame revolved on an axis, all of which movements are accomplished by the device known as Bolles' patent. The same revolving principle should be applied to the transoms, which occupy the upper three feet of the wall separating the two first-floor bedrooms from the central sitting-room. This scheme of ventilation permits the air to be changed constantly through the night, so that the same air is never breathed twice while the patient occupies the room, and it continues the fresh-air treatment even throughout the time the patient spends indoors—a most important consideration. No draperies or carpets are to be permitted except a small rug in the sitting-room. The sitting-room can be as handsomely furnished as may be desired. How homelike and cheerful such quarters can be made, even when complying with the sanitary requirements mentioned, may be judged from Figs. 5, 10 and 11, which are amateur photographs of the sitting-rooms and bedrooms in several of the Adirondack Cottages. The daily routine of life must be ordered according to the precepts of experience.

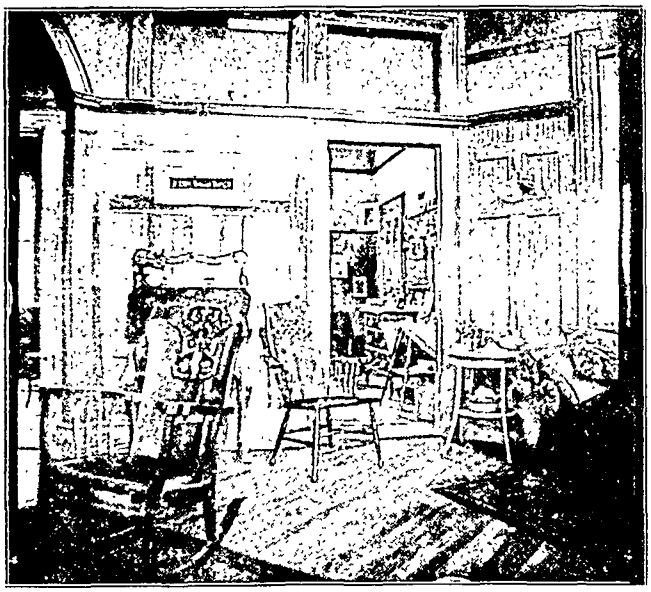

Figure 5.

I present the daily program of a patient in the Adirondack Cottage Sanitarium:

7:00 a. m., temperature taken while patient is in bed.

7:30, patient rises; sponge bath—cold or tepid.

8:00, breakfast.

8:30, patient reports at pharmacy or physician's office; while waiting can write letter and send it off in the 9:30 mail.

9:30, a stroll if permitted to exercise; or a drive, if not.

10:30, a glass of milk or an egg, or both; reads, studies or works unti 12 m.

12 to 1, rest in a hammock or on a couch in the open air until dinner.

Dinner. After dinner, rest until 3:30, temperature taken and then extra nourishment given.

3:30, milk or egg, or both.

3:30 to 5:30, patient reads, studies, works, strolls or drives, according to strength and the doctor's advice.

5:30 to 6, patient lies in the hammock or on a couch in the open air.

Figure 6.

6:00, supper.

6:30, patient reports, if necessary, at the physician's office; sits or lies on veranda, or attends some form of amusement provided in the parlor or pavilion.

8:00, temperature taken.

9:00, extra nourishment, milk or egg, and retires.

Letter-writing is limited to the bare necessities of correspondence and is done only in the morning hours.

All forms of mental and physical exertion are forbidden so long as there is active disease, with elevation of temperature above 99.4 F., or other constitutional symptoms. The reading is selected to divert the patient's mind from his afflictions to more cheerful topics, and games are allowed, provided they do not involve any harmful exertion of mind or body. The social life in the Adirondack Cottage Sanitarium is a feature which strikes every visitor as unique. Knopf remarks especially on the gay spirit which prevailed when he visited the Sanitarium in 1896.

The food provided at the Adirondack Cottages is selected by the superintendent, Mrs. Julia A. Miller, from a long experience in such work. For breakfast: fruit, oatmeal, wheatena, "Pettijohn," beefsteak, lamb chops, bacon, eggs cooked in a great variety of ways—soft-boiled, scrambled, fried, poached, made into omelettes, etc.—brown bread, wheat bread, corn bread, muffins, griddle cakes, etc. For dinner: a simple but appetizing soup, fish, roast or boiled beef, roast lamb, fowls prepared in various ways, cornbeef, vegetables, cabbage, tomatoes, potatoes cooked in an infinite variety of ways, beets, peas, beans, rice, lettuce, squash, asparagus; for desserts, ice cream, nuts, pies, puddings, custards, jellies, fruits. For supper: one hot meat, cold meats, white and brown bread, toast, some hot cereal food, baked beans, potatoes, eggs, preserved fruits, jellies, jams. Milk is furnished at the table at every meal, and is provided for each patient to take with him to his cottage for the between-meal nourishments.

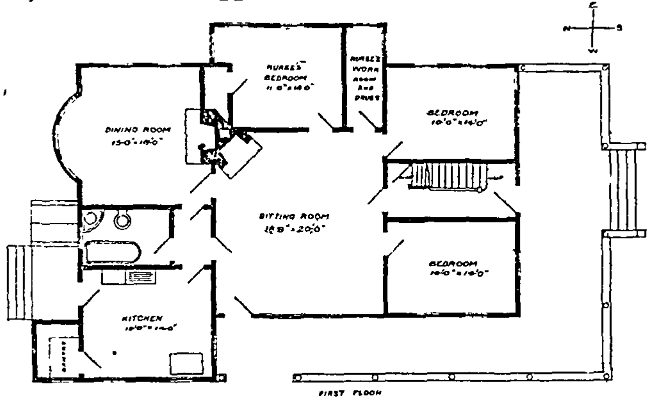

Figure 7.

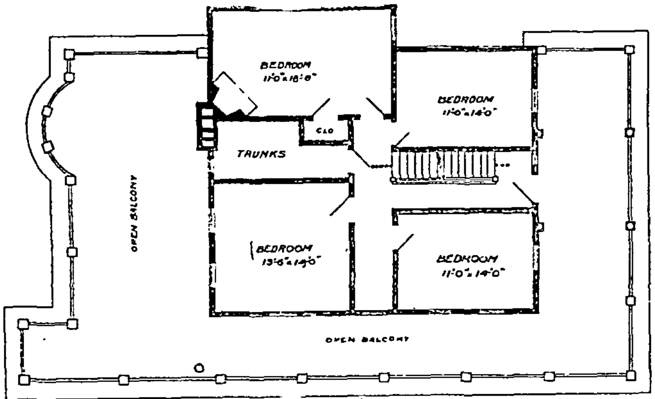

Figure 8.

With the special symptoms that present themselves for treatment, I do not purpose dealing at this time. Suffice it to say that they are all treated with as little resort to drugs and from the most common-sense point of view that can well be imagined. Dr. Trudeau and his assistants practice medicine not by rule of thumb, but according to the dictates of a large experience, based upon a profound knowledge of the broad principles underlying all disease and its treatment.

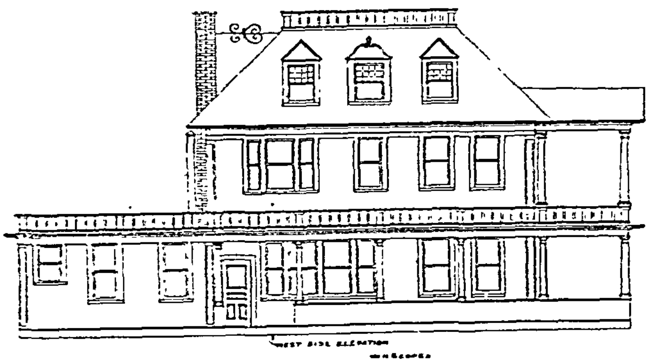

Figure 9.

Let me point out briefly what are the chief advantages of the plan proposed, 1, to the physician; 2, to the patient; 3, to the nurse; 4, to the family of the patient and to the community in which he has been infected.

The physician is enabled to keep his patient under his own supervision instead of intrusting him to a stranger. His patient remains a source of revenue to him, instead of dropping out of his practice, a consideration which has more or less force for every family practitioner. He is guaranteed by the presence of a trained nurse that each of his patients will get the best treatment possible, and that every rule laid down will be rigidly followed. This can not be said for any scheme which leaves the patient in the hands of his family. The family physician, moreover, gets the credit for the recoveries, which his early diagnosis, watchful interest and skill as a therapist have brought about. This contributes to his influence and future usefulness in the community and puts on him the necessity of keeping himself familiar with all the practical details of sanitarium treatment by which the best results can be obtained.

The trained nurse is freed from all those trammels which hamper her when she is trying to carry out the instructions of the physician in the face of the prejudices and sympathies of the patient's family. Those under her care are placed in the situations most convenient for her manipulation, and the plans presented enable her to move a patient from any room, through a window cut down to the floor, out to the veranda, thus saving strength and facilitating work. The plan provides for the easy enforcement of every sanitary regulation, preserving the nurse and the fellow-patients from risk of infection. She, with the physician, has the most favorable conditions for herself and her patients. She shares in the just credit due for their recovery and wins that repute as a successful practitioner of her profession which is as dear to the nurse's as to the physician's heart. The patient reaps every advantage that could be gained at the expense of a long trip to some health resort, a trip which, in his weakened condition, may prove most unfavorable to his prospect of recovery.

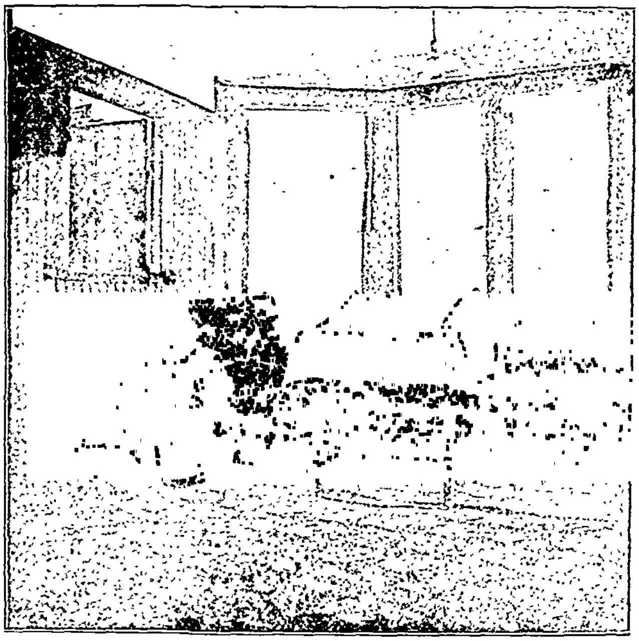

Figure 10.

The sufferer is under the daily supervision of the man he trusts most in the world, not of a busy stranger, whose few interviews with him are at best brief and confined to professional detail. He is attended by a careful nurse, who gives him every care that her varied experience can dictate. He has gained everything, and practically lost nothing, by undertaking the course of treatment.

The patient's family and community are saved the danger of infection, are given an object-lesson of incalculable value in the curability of tuberculosis and in the sanitary precautions which are effectual in preventing its spread. They have preserved to them the presence and influence among them of one who is a bearer of the heavy burdens and responsibilities of family, business and social life—for it is just such leaders among men and pillars of the social structure who are most often seized by the jealous dragon Tuberculosis.

What would be the cost entailed upon each patient who takes advantage of my plan? To completely build and furnish such a home as that shown would, at this period of high prices for lumber, plumbing, fixtures and furniture, cost $6000. The running expenses of the sanitarium must cover at least the interest on this. The following estimate for six months, based on actual experience, will represent fairly well the other features:

Figure 11.

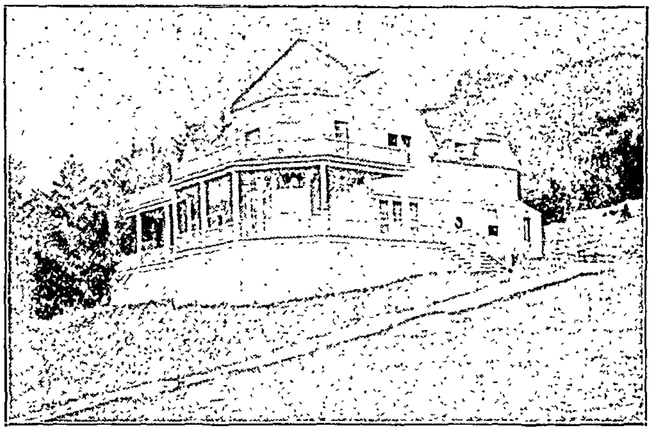
ESTIMATE FOR SIX MONTHS.

Interest at 6 per cent on $6000	$180
Services of trained nurse at $50 a month	300
Coal for cooking, 6 tons at $6 a ton (12 to 15 tons must be added for heating if the months be winter months)	36
Wood for open fireplaces, 10 cords at $3	30
Electric light, $5 a month	30
Hire of cook and maid, each $15	180
Table supplies, at $100 per month	600
Total for 6 months	$1356
Total for 1 month	226

The plan provides for the accommodation of six patients. Thus the cost to each of the six patients per month is less than $40. That is to say, at a cost of about $40 a month, apart from the physician's fees, an individual can have all the opportunities offered by the sanitarium treatment for the complete cure—in 75 to 90 per cent. of really incipient cases—of pulmonary tuberculosis, without severing the ties binding him to his domestic, business and social life.

The objection has been made by persons with whom I have discussed this plan that, without the shock that comes to a man from the complete breaking off of all his business and social relations, and without the enforced separation from them entailed by a change of climate, few persons really in the incipient stage of the disease can be persuaded to place themselves under a rigid routine of treatment. This does not seem to me a valid objection, for even in those cases which come hundreds of miles to such a resort as Saranac Lake, the ties of home and business life remain practically unbroken, and the sense of anxiety and the worry are just as great, or even greater, than if the patient were nearer home and had daily reports from his family and business associates. And it happens only too frequently here that patients coming from other more or less distant points soon tire of the routine, and are without sufficient will-power to persist in the rigid treatment without the example of fellow-patients and the discipline of a nurse, and after a few weeks or months of futile and desultory effort, or of days and nights spent in saloons or poolrooms, return to their homes discouraged, and before long meet the unfortunate consequences of their ill-advised action.

Every hope of success in this plan, as in every plan for the treatment of tuberculosis, depends on the iron will and the consummate tact of the physician and the nurse who have undertaken the task. Both of them will be obliged to study closely and deeply the methods pursued in the most successful sanitaria.



Cottage of Resident Physician, Adirondack Cottage Sanitarium, Saranac Lake, N. Y.

This leads me to a matter which has always been a source of wonder and dismay to me, namely, to find in my two years' stay here how few general practitioners ever come to Saranac Lake—in very truth, the fountain head of the rational theories of treatment in this country—to make a profound personal study of the methods actually in use here. These methods, as I have shown above, are daily offering, even to the untrained eye, the most striking illustrations of what can be done to combat tuberculosis, not merely in its earliest, but also in its middle and even later stages. I can point out any day on the streets of Saranac Lake a dozen—nay, a score—of cases who have come here in the last five or six years, and received the prognosis from even the most optimistic of physicians that death must inevitably ensue in four to six months, but who have in the face of his advice persisted in remaining here, and have been to all practical intents and purposes [illegible], and are now supporting themselves or [illegible] their daily exertions.

It is to me of profound significance that the one who hopes most in all these cases, and who is most loth to give up a patient, is Dr. Trudeau himself. He, more than any man in this country, has studied the possibilities of treatment and of cure in every form of pulmonary tuberculosis, and does not hesitate to-day to say that the more cases he sees, the less capable he feels of predicting what cases may recover.

THE SANITARIUM FOR CONSUMPTIVE SAILORS ESTABLISHED BY THE U. S. MARINE-HOSPITAL SERVICE AT FORT STANTON, N. M.*

J. O. COBB, M.D.

Passed Assistant-Surgeon U. S. Marine-Hospital Service.

There is a prevalent belief that the sailor does not have tuberculosis. Just because he is at sea breathing the purest air, we naturally think of him as having the greatest chance of escaping that dread infection. The public mind loses sight of the fact that the average sailor spends a great part of his life ashore, participating in drunken brawls, gambling in the vile holes underground in New York, San Francisco, Baltimore and all the large maritime commercial centers. The little time he spends in sleep when ashore is in sailors' boarding houses, usually filthy dives. In lieu of beds, there are rough bunks built in like a set of shelves clear up to the ceiling. Into these a little straw is thrown, and this is the bed of one man one night, and another the next, and so on. The straw is rarely, if ever, changed, and this is the only bed these poor fellows can get in these gruesome places. They need no covering, for the room is heated by the red-hot stove, around which some sit and smoke and play and drink the long night through. Such a place is awful to think about, and it is small wonder these men get sick; it is the greater wonder that every man so exposed is not rapidly infected with tuberculosis, for it is only reasonable to believe that all such places become infected in time. Then, too, it is easy to understand that one case may infect an entire crew at sea, on a long voyage, when the men are packed together like animals. The sailor breathes pure air only when he is on watch, but when he "turns in," his sleeping quarters are exceedingly bad—so bad that it is impossible to describe them adequately without subjecting one to the accusation of exaggeration.

We of the Service know that there are hundreds of consumptive sailors and our annual reports show that we have been losing on the average more than one hundred a year. Our experience has also shown us that all the cases that remain, eventually die; they drift in and out of the different hospitals, better to-day and worse to-morrow, and sooner or later serve as a necropsy study.

So it has gone for years. No movement which is purely humanitarian can be brought about without much talk and some sober writing. Officers talked and thought, but unfortunately this is usually what a non-political government officer is compelled to do—take it out in talking or writing, if he is so inclined. It is to the credit of the officers of this Service that they have ever been alert to the prevention, spread and proper control of the disease. The present surgeon-general, Dr. Walter Wyman, was the first in the Service to undertake to bring about the establishment of a sanitarium for consumptive sailors. This was many years ago, when he was a junior officer, and his efforts met with little encouragement, and although unsuccessful he can properly lay claim to being a pioneer. He did not forget his early ambitions after he became surgeon-general, and it fell to his lot to be the instrument to consummate the establishment of a sanitarium for consumptive sailors.

In December, 1898, I was sent on an inspection tour through Arizona and New Mexico for the purpose of recommending a site for the contemplated sanitarium. It was thought that as the Army had been first in the arid region—and of course had selected the most desirable site—abandoned posts would best serve our purpose as fulfilling the requirements of large tracts of land, good water-supplies, and that the data published by the officers of weather and other conditions would be very valuable as a guide.

After careful examination in both territories, Fort Stanton was decided on as best suited for our purposes, specifically and generally. The weather reckonings made by the Army, together with special reports by its officers serving here in early times, showed mild winters with delightfully cool summers. It was necessary to have a station combine these two features or else have two stations, one at a low level for winter and one higher for summer, for otherwise patients at low levels would lose in summer all that had been gained in winter. With its undoubted advantage of climate, a generous water-supply, a large reservation, and with substantial stone buildings, it is an ideal site.

Fort Stanton is situated in Lincoln county, N. M., about six miles from Capitan, the terminus of the El Paso and North Eastern railroad. The elevation is 6126 feet. There are 38 buildings of various sizes, most of them being of native rubble stone. There is room for 200 patients, besides quarters for officers and attendants. Repairs are going on, and new machinery is to be introduced shortly. A modern steam laundry and a one-ton ice plant are now contracted for, and the plans and specifications are being prepared for an electric-light plant and extensive repairs, which will be commenced this fall. All the buildings will be made modern, and the appointments will equal any in the country. The laboratory will be conducted especially in the study of the disease. The apparatus for the purpose is already on the ground and is temporarily set up in an old building awaiting the repairs on the executive building, where there is to be a room set apart for this purpose.

There is a large farm and garden attached to the station. On the farm is being raised all the forage and most of the grain for the horses, milk cows, cattle and chickens. In the garden we have a source of pleasure not often found at such institutions. We have all the fresh vegetables needed and such vegetables as can not be bought in this vicinity.

Our herd of Jersey milk cows supply all the milk used at the station. While speaking of the cows it may be of interest to describe the method of dealing with the milk. We try to have all the patients follow as nearly as possible the method of taking milk described by Dr. Bulkley. To make this a little more perfect, it is necessary that the milk should always have a given percentage of fat, and to obtain this our milk is cooled immediately after milking and run through a separator. The cream will turn out about 20 per cent. (volume), and then this is added to skim milk to make it 20 or 25 or 30 per cent. of cream, as is prescribed by the medical officer. In this way there can be no marked variation in the percentage of fat, as there would be on cold, stormy days, or in change of food or other well-known conditions, which cause a cow's milk and fat percentage to vary. We make some butter and buttermilk, and intend to make kumyss and kefir. The patients have increased so fast that we are not altogether prepared for them, as it was the original intention of admitting only twenty the first year.

---

* Presented in a Symposium on Tuberculosis, to the Section on Hygiene and Sanitary Science, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The reservation is very large and it is the intention to fence it for pasturage and to raise our own sheep and beef cattle. This will be not only a paying operation, but will give us fine meats. Fort Stanton was set aside for a sanitarium by executive order dated April 1, 1899, and the station was officially opened April 27, 1899. To date, there have been 70 patients admitted, 6 of whom have died, 17 have been discharged, 13 improved and 4 apparently recovered. Seven of those discharged improved are still under observation as attendants, of whom all appear to be well except one. This one, however, was a bad case, but is now doing well. Three cases reported as improved are working in the vicinity. One of these had both lungs badly infected, but as he was strong, had no fever and felt well, he obtained employment at the mines near here and is working every day. He reports that he still expectorates, but otherwise is still improving. Another has just gone to work. His trouble originally was a tubercular empyema, for which several ribs were partially resected. The other man is well.

Of the cases remaining we shall probably lose a few, but seven seem to be entirely cured and will be sent back as soon as the hot weather in the East is over. Twenty-one seem to be arrested, though the evidence of the disease still persists. Of those who died, only one was a good case when he came. This man had a small cavity, which apparently began to heal. He began to improve after a time, and would probably have recovered but for contracting tubercular pneumonia on his good side. Of the other cases which died, not one was considered, by the officers of this station, as good subjects for transfer and all died shortly after reaching here.

To get the patients constantly in the open air has been a most vexatious problem. Most of them came here from hospitals which were heated by steam and would have rebelled had they been put in the open air to sleep immediately after arriving. Knowing the sailor as I do, it was necessary that all this be brought about indirectly and gradually, and now they are very enthusiastic for the open air. All sleep with the windows and doors open and in the day they walk about, swing in hammocks here and there under the cottonwood or box-elder, ride the native ponies, which are for their use, or recline in easy chairs or amuse themselves by doing odd jobs. One man bought himself a tent and sleeps out every night.

Fig. 1.—Looking Across Parade Ground, Showing Capitan Mountains to the Northeast. Fort Stanton, New Mexico.

To find means of diversion or amusement has been a hard problem and will continue to be so. While they are running fever or otherwise doing badly, I have no trouble, but just as soon as they begin to get well they become restless for the water again.

In the matter of treatment, dependence has been put in keeping the men constantly in the open air and giving the best of food. However, we have had several cases with severe complications, malaria being the most frequent. Many of the men have [illegible] localities where they had [illegible] [illegible] have several under [illegible] organisms. D[illegible] loss of appetite in some cases hopelessly discouraging, these complications compelling us to give some medicine. Just here it is well to warn those who have not had much experience with heroin to be cautious in its use; the habit is easily contracted.

We have been making some careful observations of the effects of altitude. If mere clinical experience is worth anything at all it leads me to believe that most cases become anemic shortly after coming here. Of course, the blood-count and hemoglobin percentage are increased, but I feel certain, without being able to prove it, that it is not actually true. After a time the proper relative standing of the blood-count and hemoglobin is reestablished and the increase is actual, though the readings of the instrument may not show an increase. I have about decided that the blood tests can only be of interest as a guide to each individual's relative condition and progress. Collectively the tests are misleading.

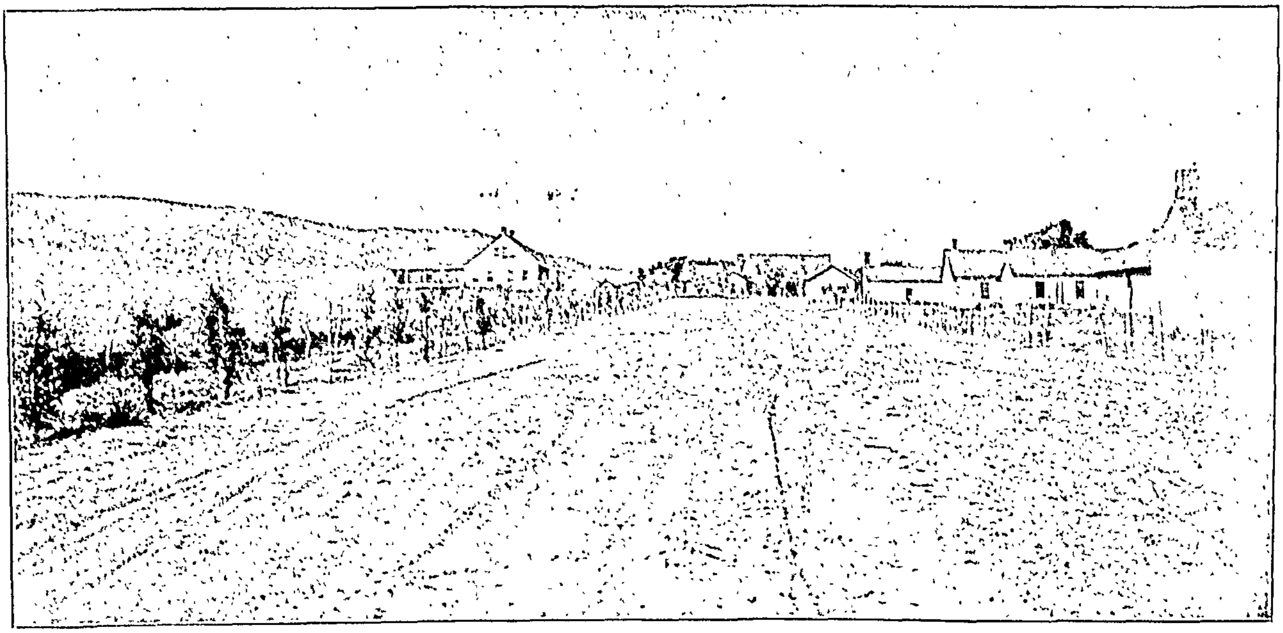

Fig. 3.—Looking up South Avenue, with Cottonwood Limbs Which Were Set Out This Spring, and Which Are Growing, Showing White Mountain to the Southwest and Mesa to the South. Fort Stanton, New Mexico.

We have noticed, too, that the majority of patients lose weight at first, notwithstanding an improvement in appetite and general symptoms. The urea percentage is markedly increased and has continued so with cases under observation.

The method of handling the sputum and preventing infection will be of interest to the general practitioner. There are no half-way measures. The theoretical part is nearly perfect and its execution will be almost so when all the sterilizers are put in place and in operation. I am happy to say that there is no such thing at this station as a spittoon, which demonstrates that a large institution can be run without one. To have a spittoon lowers the standard of effectiveness at once, for no one will deny the dangers of using one. Any method of sterilizing sputum except by incineration or steam heat is not perfect. Any method of collecting sputum by the process of ejecting it from the mouth at a distance into the receptacle is unsafe. The receptacle must be brought close to the mouth. The patient must have his own receptacle, for it is disgusting to see the sputum of others. To secure this desirable end we are using sputum-cups and pocket sputum-flasks. Each patient has a flask and cup, but I find that they dislike the cup and nearly all of them want to use the flask only. They carry the flask wherever they go, and use the cup in their rooms. Once a day at a given time every cup and bottle used is carried to the sputum room and there checked off, by an attendant, from a complete list of the patients. It is necessary to keep close watch on each individual, and take note whether he brings his cup and bottle for sterilization, for if we did not he might empty the sputum in the sinks and closets.

exasperatingly narrow in matters pertaining to public health, unless his pocket or the pockets of his constituents are affected. Let a wide and destructive epidemic break out among animals and then how prompt legislation is introduced to suppress it! There is money! It is a crying shame that this country, one of the foremost in all grand evolutionary movements, should have waited till the closing year of this century before joining in the sanitarium movement against the worst foe of mankind. What excuse can there be? None. The results were well known to be good and it was not an experiment. The way had been marked for us by Germany as a leader in this crusade with her first sanitarium in 1859 at Goerbersdorf, or 1854 according to Von Leyden. The impetus given to the sanitarium move-

could go—and die. Make them comfortable has been the cry. The end was inevitable. A new sense of responsibility is now thrust upon the man or woman with means, for this frightful death percentage must not be. The case must be diagnosticated early, and that is the awful and fearful responsibility of the physician. And look to it, you who make snap diagnoses with the unaided ear through the patient's clothing and who never make thorough chest examinations of women at all; and you who stain one specimen of sputum and finding no bacilli declare the trouble is only bronchitis; or you, the worst offender of all, who withhold from the patient the true nature of his disease, allowing him to go on expectorating at random, spreading the infection broadcast and to the members of his own household! And I say to these, and to the vampire who holds his patients, drugging them to death, finally abandoning them when they are in a dying condition by sending them to health resorts, that the public is awakening to the realization of the danger of delay and in wrath will have none such as you.

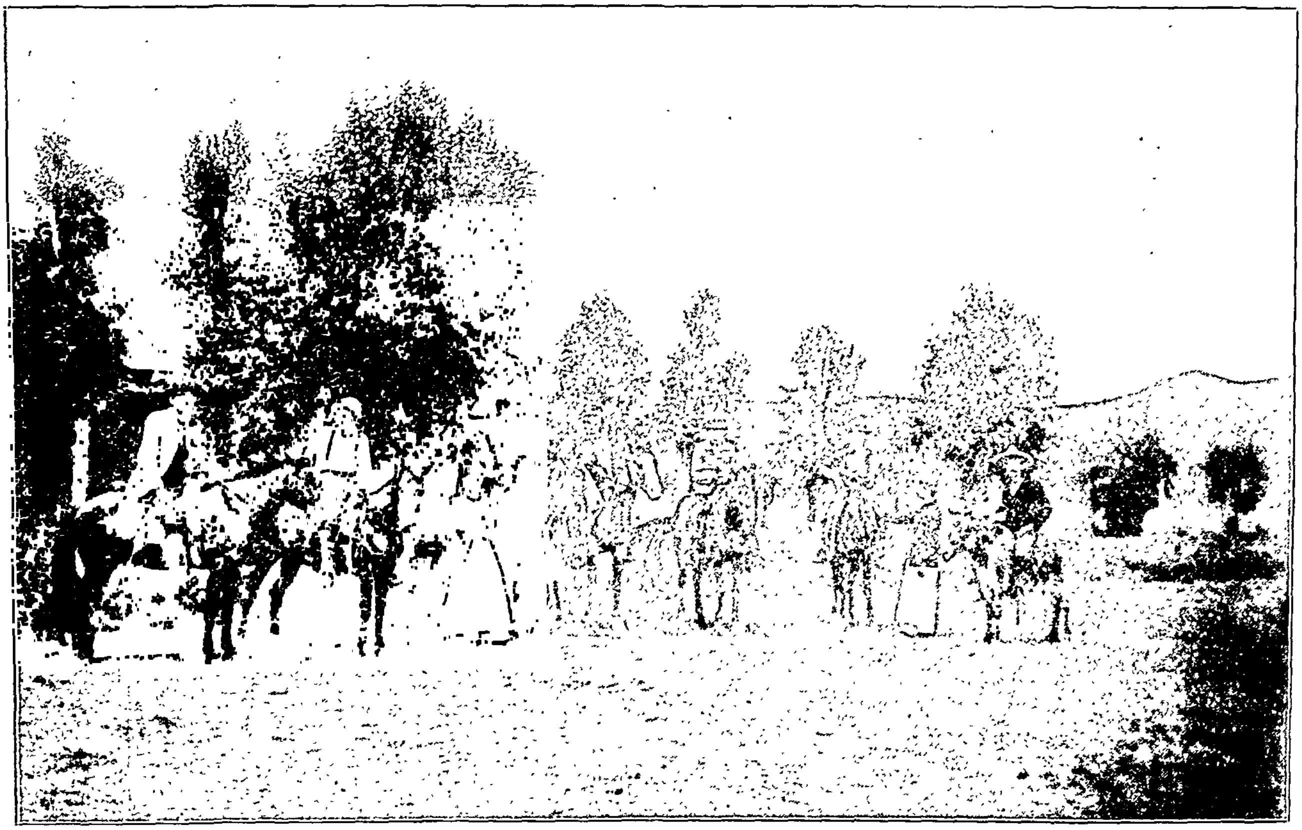

Fig. 5.—Patients Ready for a Ride. Fort Stanton, New Mexico.

The phthisiologist can not make a successful issue of this undertaking without the aid of the conscientious general practitioner. I am told that in Germany every medical man is alive to this question and the most careful examinations are being made to detect the disease in the first stage. Tuberculosis is not such a grave disease if taken in hand early and sent into the pure open air.

Medical men have no money, and if they diagnosticate their cases early, then the public at large, through its wealthy citizens or its municipal, state or governmental authorities, becomes obligated morally as well as socially and economically, to give the patient a chance for his life. It must not be care for the doomed and dying—the reach must be greater and extend out to the home of the sufferer. Man of wealth! Woman of wealth! Do not put your money in grand edifices in the overcrowded city where your philanthropy only serves to make a doomed consumptive's life comfortable for a few weeks, at most a few months. Go to the woods all about you and put these people where there be a chance for recovery and where they can return to their homes as useful citizens. This much may be hoped for, but even if the patient should die, we will have gained by removing the focus of further infection. This to me is the most important side of the subject.

All grand movements begin first with suggestions, and nothing is ever accomplished except by discouraging set-backs at every turn. Men like Trudeau can not help but look back with pride on their accomplishments under the very great drawbacks they must have had. What a sensation must the founder have had when, in 1884, the first little cottage at Saranac Lake came into existence! His was no selfish ambition; what must have been his hopes and fears? He would have been laughed at then if he had gone to Congress or his state with a bill to help erect this same little cottage. His patients were not animals and there was no loss to the pocketbook, therefore no need of legislative help.

The public is awakening to the danger. Towns, cities and states have become aroused, and now that our Government, first through the Marine-Hospital Service, and then very shortly after by the Army, has given its official cognizance of the importance of stamping out the white plague we may expect in the next few years a forward move of which we may be proud . Of course the work done by the government may, in a way, be comparatively small; yet of all the patients admitted were not one to recover, were all to die, still the good done to the community at large is inestimable. So many foci of infection removed from our ships in their world-encircling courses; from the barracks, camps and hospitals of the Army; from the sailors' boarding houses; from our general hospitals, where we have had such a discouragingly large percentage of deaths; to bring all these patients away from thickly populated centers, where they undoubtedly spread the infection, is an accomplishment itself of no mean importance.

With such opportunities for study afforded by the well-equipped laboratories, the ever-increasing clinical material, it is not too optimistic to feel that we may help to clear away one by one the many obstacles yet confronting the world in effecting immunity and cure.

THE DIAGNOSIS OF PULMONARY TUBERCULOSIS.*

ROBERT H. BABCOCK, A.M., M.D.
Professor of Clinical Medicine and Diseases of Chest, College of Physicians and Surgeons.
CHICAGO.

This may be a matter of considerable ease, or one of extreme difficulty, depending on the stage of the disease and the nature of the pathologic conditions. Let us first consider its diagnosis at an early stage. Tuberculosis is an infection, and as is the rule with infections, it occasions a rise of temperature even at its incipiency. Except very rarely, when the infection is violent or the disease assumes the acute pneumonic type, the elevation of temperature is slight, and may even escape detection. If the thermometer shows a constant elevation ranging between 99.5 and 100.5 F. it is in a suspected case strongly suggestive of tuberculous infection. The temperature should be registered not merely night and morning, but four or five times daily, as, for instance, at 9, 12, 3, 6, and 9 o'clock.

The pulse is as a rule accelerated and to a rate out of proportion to the temperature. But it should be remembered that an individual who is under examination for suspected tuberculosis is apprehensive, and therefore likely to manifest acceleration of the pulse. Nevertheless, the pulse-rate will be found to range in the neighborhood of 100, not rarely 120 or thereabouts. It is usually a pulse of low tension, and this is more characteristic than is an increase in the frequency. Undue rapidity together with lowness of tension forms, in the absence of signs of cardiac disease, a very suspicious combination. Its value is enhanced if conjoined with increased body temperature between the extremes noted above. The respirations may or may not be increased. As a rule in incipient cases there is neither subjective nor objective dyspnea.

Loss of weight is a suspicious circumstance and is an invariable accompaniment, I believe, of incipient pulmonary tuberculosis. It is so often slight that it escapes the patient's notice, and therefore his statements are not always to be relied on. The value of this symptom depends largely on its association with other symptoms and signs; without them it can scarcely be held suggestive of tuberculosis. Decline in strength and a falling off of appetite are also to be considered in doubtful cases, but are of small evidential value.

Cough is usually the first symptom to attract the patient's attention and to arouse apprehensions in the mind of the physician as well as of the patient. Although it is frequently symptomatic of this disease even at its invasion, still it is not invariably so, and taken alone has but small diagnostic value as regards pulmonary tuberculosis. In every suspected case in which physical signs do not settle the question of diagnosis, the upper respiratory tract and the heart should be carefully examined for an explanation of the cough. Aurists will say that even the ears should not be left out of the field of exploration.

Sputum is, for a time, absent in cases of beginning tuberculosis, but when present exhibits nothing characteristic, unless, of course, it shows bacilli. Even hemoptysis is not pathognomonic, although highly suspicious of pulmonary tuberculosis. When due to a deposit of tubercles in the lungs, physical signs may usually be detected, or there will be some of the suggestive symptoms already considered. If not, then the gums, nares, pharynx, larynx, trachea and heart should be carefully examined for a possible source of the hemorrhage. In conjunction with a slight rise of temperature, loss of weight and cough, hemoptysis is very significant of tuberculosis.

Having thus briefly considered the symptoms attending incipient pulmonary phthisis, let us now take up the physical signs.

Inspection.—It is not necessary to describe the contour of the thorax with its narrow apices, weak musculature, deficient expansion, etc., which so often characterizes the tuberculous diathesis, and therefore I shall pass at once to such evidence of early tuberculosis as may be gained by inspection. One of the earliest ocular signs is lessened expansion of one apex, observed oftentimes in the supraclavicular region. This area may be slightly depressed or retracted, as compared with the other side. In rather more advanced cases, or those in which the tubercular deposits are not so limited, these same changes may be noted in the infraclavicular region as well. Another sign, which by Carcassonne and others is said to be a very early and significant one, is atrophy more or less marked of the scapulothoracic muscles on the affected side. That drooping of the shoulders, which forms a part of the phthisical habitus, may be seen at an early stage, but is generally present when the disease is more advanced.

Palpation does not furnish very reliable or positive information, except as corroborative of that obtained by other means. It is so largely influenced by individual peculiarities. Nevertheless, when in a suspected case there is a marked difference in the pectoral fremitus of the two apices, that apex at which it is distinctly increased is apt to be the seat of tubercular deposits. This is particularly likely to be the case in the suprascapular region, for a reason which is about to be stated.

Percussion is the means generally relied on for the detection of incipient pulmonary tuberculosis, yet it is not always so trustworthy as is auscultation. Dulness at either apex is usually regarded as indicative of the disease in question, and justly so. Still, one should always bear in mind that it is normal for some individuals to show slightly less resonance at the right apex. Therefore, in estimating the importance of trifling dulness at the right summit of the chest one must also consider the presence or absence of the symptoms of constitutional disturbance already spoken of. It is common for physicians to look for impaired resonance below the clavicle, whereas in my experience it is far more frequently found above and in the suprascapular region. This is owing to the fact that, as pointed out by Fowler, deposits of tubercles take place earlier and more frequently at the tip of the lung [illegible] its bc [illegible] d on the posterior aspect of the [illegible] patch of deficient resonance may often be detected behind in the suprascapular fossa, when in front there is no appreciable dulness. It is also in accord with my experience to find diminished resonance early along the vertebral border of the scapula, to uncover which it may be necessary to have the patient fold his arms across the chest in such a manner as to draw the shoulder-blades apart. For the sake of emphasis let me repeat that whenever these changes, however slight, exist at the left apex, it is strongly indicative of tuberculous disease. Finally, an initial alveolitis may sometimes occasion slight hyperresonance of a tympanitic quality. At a later period dulness replaces this tympanitic resonance.

---

* Presented in a Symposium on Tuberculosis, to the Section on Hygiene and Sanitary Science, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Auscultation is a valuable method for the early recognition of pulmonary tuberculosis, yet to be of full service requires great familiarity with normal breath-sounds and slight transitions therefrom. As with regard to percussion, so also with auscultation; one must remember that it is normal to some individuals for the respiratory murmur at the right apex to be less vesicular, that is, bronchovesicular, as compared with the left. Therefore slight modifications on the right side do not have the same significance as when they are found at the left. Slight dulness and bronchovesicular breathing at the right summit of the chest, whether in front or behind, do not of themselves, without some of the more significant symptoms, constitute sufficient evidence on which to base a diagnosis of tuberculosis. Their value would be greatly enhanced if in a circumscribed area the inspiration should be wavy or jerky. Occurring on the left side, where vesicular breath-sounds are the rule, a bronchovesicular quality of the respiration is highly suspicious. When there is distinct bronchial breathing at either apex, it is not normal, but indicates disease, and being associated with unmistakable dulness, usually warrants a diagnosis of tubercles. Râles are not always present in incipient cases, and often when not heard on quiet respiration will be elicited by a deep inspiration or the act of coughing. Under these conditions they are fine crepitant or subcrepitant crackles heard toward or at the end of inspiration. They convey an impression of being moist, and not infrequently are mingled with fine bubbling râles of a somewhat larger size. These adventitious sounds may be very limited in extent or may occupy the entire dull area. Heard in either of the suprascapular fossæ they furnish extremely strong evidence of the disease under consideration. In front, especially along the inner margin of the lung, friction may be mistaken for these râles, yet should any such minute crackling râles be detected, it is generally safe to assume that tuberculosis is responsible for their presence. Incipient tuberculosis is as a rule unilateral, and bronchitis of non-tuberculous nature is bilateral. Moreover, the râles it produces in front are either heard over the course of the larger bronchi and are of large size, and toward the base rather than at the summit. The conjunction of dulness, bronchovesicular or bronchial breathing with these minute râles at one or both of the apices posteriorly will generally justify the conclusion that the lung is tuberculous. When these signs are distinct, doubt of their significance can scarcely be entertained. Moreover, in such pronounced cases there are usually well-marked constitutional symptoms. There is usually sputum, and this will very probably contain bacilli. The difficulty is in incipient cases which furnish no physical signs or such as are so ill defined that even a skilled examiner is not quite certain of their existence. If the temperature, weight, pulse-rate, state of the patient's strength, examination of the sputum, etc., can not help one out, then he would do well to postpone a definite diagnosis until by repeated examinations he can at length arrive at a positive conclusion. Not infrequently an experienced observer may become mentally convinced from the family and personal history, as for instance of previous pleurisy, from the general make-up and appearance of the individual, from the symptoms and from the *tout ensemble* of physical signs, that the patient has tuberculosis, and yet he does not feel warranted in giving expression to his conviction. If it does not seem best to wait for time to clear up the doubt, then recourse may be had to tuberculin, of which I will speak more fully a little later on.

Mensuration of the chest, which should include not only its expansion, but also its relative size as proportioned to height, the determination of the vital capacity by means of the spirometer, the individual's weight as related to his height, these and other accessory circumstances have their diagnostic value, but can not be more than referred to in the limts of this paper.

As regards the employment of the old tuberculin for diagnostic purposes, there is wide diversity of opinion, so wide indeed that statements are flatly contradicted. The opponents declare that it is not only unsafe, but also that it is unreliable, producing a reaction in syphilis and sometimes failing in cases of tuberculosis. The advocates of its use state the opposite just as positively. By those who have employed it extensively it is, however, stated that injurious effects follow too large doses or too frequent repetition of the injections. Therefore, the precautions to be observed are as follows: 1. Use Koch's old tuberculin, not tuberculin R. 2. Let the initial dose be .5 to 1 milligram of the tuberculin; larger doses than this to begin with are sometimes employed, but it is better to err on the side of caution. 3. If the first injection is not followed by the characteristic reaction, double the dose may be injected after an interval of three days. Some advise a shorter interval than this, but as there can be no other objection to waiting so long than the loss of time, it is again better to be over-cautious. 4. Should this dose again not be followed by reaction, double the second dose may be given after another three days. It will seldom happen that a tuberculous individual will not react after receiving as much as 5 milligrams, which may be regarded as a safe third dose. Occasionally, a large-sized and insensitive person will require even as much as 10 milligrams, but this amount should be reached gradually. The characteristic reaction consists of a rise of temperature of 2 degrees F. above the patient's average daily temperature as determined by repeated observations during several days prior to the first injection. There is often also a feeling of malaise and some increase of cough. This reaction generally takes place within twenty-four hours following the injection, but may be delayed to quite twenty-four hours. Carried out with the ordinary precautions stated, I consider this means of diagnosis safe, and have no hesitation in recommending it in cases in which careful physical examination does not enable one to arrive at a conclusion. I should not, however, advise recourse to this diagnostic procedure without having first exhausted other means at hand.

Of late we have been hearing much of the service rendered by the X-ray in the field of diagnosis. Tuberculous infiltration of an apex is revealed by a slight shadow in the affected area. It also affords a means of detecting enlargement of the bronchial glands. This was recently very well shown in the case of a man who was sent to me for diagnosis. The skiagraph also showed slight opacity of the right apex, and thus confirmed what I had discovered by physical examination, yet which was so faint as to leave room for doubt.

It has also been recommended that small doses of potassium iodid, 3 grains three times a day, be employed to clear up doubtful cases. If there is slight alveolar catarrh of one apex producing uncertain physical signs, this potash salt will occasion the development of fine râles in the affected area or so modify the quality of the breath-sounds as to aid in the diagnosis.

Agglutination of the blood, after the Widal method, is too recent and not sufficiently proved to require more than a passing mention. There now remain only a few remarks concerning the diagnosis of advanced pulmonary tuberculosis. When the disease has progressed to this stage, there is generally mixed infection and it assumes the picture of ordinary consumption. As a rule there is no difficulty in arriving at a correct diagnosis in these cases. The symptom-complex alone is sufficient, and yet I would be the last to advise a reliance on symptomatology without examination of the chest. Occasionally, in aged people or persons with extensive chronic bronchial catarrh, it is not always easy to decide whether tuberculosis may not exist in such cases. A correct interpretation is facilitated by bearing in mind the fact that tuberculosis is a unilateral disease as a rule, and that the apex is always more involved than is the base of the lung. Of course, when the disease has progressed to an advanced stage, both lungs are likely to yield signs of the disease; but one can generally determine that the disease is more extensive or more advanced in one than in the other lung, one having been affected primarily, the other secondarily. Although râles of associated bronchitis may exist throughout, they are likely to be more numerous at the bases and of a different character from those of tuberculous apex diseases. These latter are of a crackling kind, small or medium sized, and are found together with dulness on percussion. If the breath-sounds are not so obscured by râles as to be of undeterminable quality, they are bronchovesicular, bronchial or cavernous. Dulness at the base and resonance at the top do not occur in pulmonary tuberculosis, unless very exceptionally a basic affection becomes secondarily tuberculous. When anfractuous cavities have riddled an upper lobe, or tuberculous foci are scattered with comparative healthy intervening tissue, and not a normal opposite lung with which to make comparison, it may not always be easy to determine the exact nature of the percussion note. One must then rely on auscultation to help him out, or he must await the result of treatment, in the hope that by clearing up the bronchitis at the base he may then definitely ascertain the condition of the apex. The detection of bacilli in the sputum will settle the nature of the case; but these are not always present in chronic ulcerated phthisis, and the failure to detect bacilli is no proof that the affection is not tuberculosis.

It may be set down as a general proposition that dulness and bronchovesicular or bronchial breathing and râles at the apex indicate pulmonary tuberculosis. Signs of excavation corroborate the diagnosis.

Limited space forbids further consideration of this subject. I have endeavored as far as possible to present the subject in a general way applicable to the vast majority of cases and not to detail the multiform deviations that may be encountered. Neither have I attempted to discuss the diagnosis of acute cases of the pneumonic type, but merely the form of the affection most often met. Acute tuberculous bronchopneumonia, being an apex disease, is governed, so far as concerns its physical signs, by the same principles that underlie the diagnosis of the chronic varieties. The main difference consists in the greater severity of symptoms and more rapid development of the changes on which the physical phenomena depend.

103 State Street.

NOTIFICATION OF TUBERCULOSIS.*

ARTHUR R. REYNOLDS, M. D.
Commissioner of Health.
CHICAGO.

Notification of the existence of tuberculosis is not demanded by the Department of Health of Chicago.

Notification of a contagious disease to a health authority implies some action on the part of that authority; and no action commensurate with the existence of a disease which, it is estimated, affects one in every sixty of the world's population, is physically possible with the limited resources of our department.

This, however, is not the most important objection to the notification scheme. If a consumptive person is properly instructed how to destroy the contagion in his sputum there is no reason why restriction should be placed on his movements, and in many cases he may be a useful and productive member of society for years. Any public action that would tend to brand him as an outcast or one to be shunned would be a great wrong, if the sufferer took proper care of his expectorations.

Then, again, if we would prosecute those who fail to report tuberculosis, experience proves that it would lead to concealment of cases, and as the disease is generally chronic, the patient may change his residence many times before he dies.

I have never been able to convince myself that tuberculosis should be a notifiable disease. The diagnosis of pulmonary consumption is frequently surrounded with great difficulty, and if we endeavor to enforce notification we would have to be able, promptly and indisputably, to prove the existence of the disease. How great and how absolutely insurmountable this difficulty is, is demonstrated by post-mortem statistics, which show that out of every hundred persons "posted" for other causes of death twenty-two present evidence of healed tuberculosis.

The only object to be gained by notification would be to enable health officials to warn the sufferer of the danger in his sputum and to placard the house to warn off approaching visitors. It is my belief, based on practical experience with other contagious diseases, that these results may be better obtained through the voluntary coöperation of the profession than by attempts to compel the attending physician to report consumptive cases. In the June, 1899, Bulletin of the Department is an article which shows conclusively the advantages of the former over the latter system in such diseases as diphtheria and scarlet fever. The following is the article referred to:

VOLUNTARY VS. COMPULSORY NOTIFICATION OF CONTAGIOUS DISEASES IN CHICAGO.

On resuming charge of the department in the spring of 1897 the commissioner found the plan—inaugurated by him in 1895—of allowing physicians to "assume the responsibility" of enforcing precautionary measures against the spread of contagion in cases of diphtheria and scarlet fever attended by them, had resulted in a material increase in the number of notifications received and of disinfections performed. Its operation had also very largely removed the friction between the department and the medical profession engendered by previous efforts to compel reports of contagious diseases by prosecutions, fines, etc.

---

* Presented in a Symposium on Tuberculosis, to the Section on Hygiene and Sanitary Science, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

To what extent the reports under the old system were defective may be inferred from the following figures of cases reported, premises placarded, etc., during the year preceding the innovation: The total notifications of diphtheria cases in 1894 were 1921; and it may be noted that the total diphtheria deaths recorded were 1293. These figures would give the incredible mortality rate of 67.3 per cent. for diphtheria. In 1897 the total diphtheria notifications were 3103 and the recorded diphtheria deaths were 726.

In the latter year, 1897, therefore, while there was a reduction of 44 per cent. in the number of recorded deaths there was an increase of 62 per cent. in the number of notified cases—an improvement of 106 per cent. in the notification of diphtheria cases in proportion to reported deaths as compared with the year 1894, before the adoption of the new plan.

Total area disinfected in the 1897 period, 1,075,581 cubic feet. In the 1899 period, 7,669,641 cubic feet, or more than six times the area disinfected in the six months of 1897.

* "All other" includes cases of tuberculosis, measles, typhoid-fever, smallpox and glanders.

DISEASES TO BE REPORTED: Diphtheria, Measles, Membranous Croup, Puerperal Fever, Scarlet Fever, Smallpox, Typhoid Fever, Whooping Cough. Optional—Tuberculosis.

NOTE.—Where the Attending Physician will undertake to enforce necessary measures against the spread of contagion in a case of any of the above-named diseases, the intention should be indicated by writing in the word assume in Entry No. 8. If this be done the DEPARTMENT will not placard the premises - except in Smallpox. If it is proven that efficient precautions are not being enforced, the premises will be taken charge of, placarded and quarantined by the DEPARTMENT—Tuberculosis excepted

If the Physician does not see fit to assume this responsibility, the word decline should be written in the blank space, when the DEPARTMENT will placard and quarantine as may be necessary for the protection of the neighborhood. Absence of any indication will be construed as declining the responsibility and the DEPARTMENT will take action accordingly.

Where the responsibility is assumed, the Physician must cause neighboring families to be fully warned against the disease and must prohibit members of the infected family from exposing others to the risk of infection

8 See NOTE above.—I..........................the responsibility of preventing spread of contagion from this case.

....M..D.

Address..

Comparing the first six months of the present year—1899—with the corresponding period of 1897 the increase in notifications is much more marked. In 1897, between January 1 and June 30 inclusive, there were 1747 cases of the notifiable contagious diseases reported. Between January 1 and June 30 inclusive of the present year there were 4320 cases of such diseases reported—an increase of 147 per cent. in notifications.

The following table, compiled from the monthly bulletins, shows the number of contagious-disease cases reported; the number of premises placarded on such reports; the number of contagious-disease premises disinfected by the department; the total area disinfected; and the number of contagious-disease funerals supervised—during the respective periods:

The accompanying table shows an actual increase in the two years of 147 per cent. in the number of cases of the contagious diseases reported: of 73 per cent. in the number of cases of the contagious-disease premises placarded; of 400 per cent. in the number and of 600 per cent. in the area, of such premises disinfected; and of 70 per cent. in the number of contagious-disease funerals supervised by the department.

These results of the "assume-the-responsibility" plan—by which it was sought, primarily, to secure the voluntary, in lieu of the law-compelled, co-operation of the medical profession with the department—are the justification of the experiment and the sufficient warrant for its continuance and development.

The ordinance requirement of uncompensated professional service by physicians, in the report of their contagious-disease cases, had not only been a demonstrated failure, but the tactless efforts to enforce the provision had alienated a most valuable ally of any health department. Now, more than ever before in its history, this department is in touch with the physicians of the city; more fully than ever it receives the information from them necessary to success in its efforts to restrict the spread of the communicable diseases and to protect and promote the public health.

It is not meant by this to imply that perfection has been attained. There are still too many physicians who "assume the responsibility" on the notification report and neglect to discharge the responsibility in practice. Too many visitors are allowed by them in infected rooms and premises; too many children, still in the communicable stage of disease—especially of scarlet fever—are permitted to mingle with others and even to attend school: not enough warning to the neighborhood is given in all cases; disinfection by the family, under their direction, is not always thorough and efficient; and there are many other laches and sanitary sins, both of omission and of commission, on the part of the weaker brethren of the profession.

But these are in a minority steadily becoming smaller. Constant pressure by the department through repeated warning and counsel—the holding up of burial permits—the reference of certificates to the coroner for investigation in aggravated cases—and other corrective, mainly educational, measures are remedying these defects, and the fact remains that an immense improvement has already been effected by this plan in the control of the communicable diseases in Chicago.

On the contagious-disease notification card of the Department provision is made for the report of tuberculosis, but it is "optional," and premises are never placarded or quarantined on such report. Cases of destitute consumptives, whose conditions are a menace to the neighborhood, are taken charge of, admission to such provision as exists—usually to Dunning—is secured, and the premises are disinfected by the Department. The foregoing is a reproduction of the notification card:

After being vacated, either by death or removal, premises that have been occupied by a consumptive are also disinfected by the Department on request of the attending physician; but such requests are not numerous, although increasing from year to year.

In this connection I would urge, as to Chicago, at least, that the attending physician should direct disinfection himself after tuberculosis—as well as after other contagious diseases—in families able to defray the expense, and should exact his fee for this service. This would largely relieve our overworked disinfecting corps and enable it to devote greater efforts to the destitute—those unable to pay—who, as a rule, require more thorough work than the well-to-do.

I do not understand why so many physicians delegate this part of their professional opportunities to public officials. In the nature of things, the attending physician is more valuable than any public official can be. From his frequent visits he is better informed as to the requirements and conditions of his case; he is relied on by the family as to advice and precautions necessary to prevent spread of the contagion to others; and he is either openly or covertly considered responsible for any spread, should it occur. These services are not taken into account in any fee bill; but if their value should come to be generally understood by the public their adequate compensation would naturally follow.

He is the most potent instructor of the public on the danger of infection generally, and of tuberculosis in particular, and I believe strongly that the public needs only to know what is necessary and wise to do to prevent tuberculosis, and all will be done that is useful. The best agency to this end is a wise, vigilant and energetic medical profession, properly taught in the medical colleges, and supported and reinforced by the medical press and the lay press as well.

Notification means policing, quarantines and force through public officials. Education means a reduction of the disease by intelligence and natural methods, and it teaches that the responsibility ultimately rests on the individual, who will be as zealous for the enforcement of preventive measures, when he knows and understands, as will be any public employee.

THE CORRESPONDENT of the *Gazzetta degli Ospedali* states that the average number of persons present at the section meetings of the International Medical Congress was not over seventeen.

NECESSITY OF EXAMINATION OF THE SPUTUM IN THE DIAGNOSIS OF PULMONARY TUBERCULOSIS.*

C. M. WOOD, M.D.
Physician to Cook County Consumptive Hospital.
DUNNING, ILL.

It has been wisely said that failure to make use of the well-recognized means of clinical investigation leads to more errors in diagnosis than does ignorance. The laity sometimes neglect to take advantage of the wonderful discovery of Jenner, and we wonder at their apathy. What shall we say of the physician who, in so serious a matter as the diagnosis of phthisis, neglects to make use of the simple and beautiful staining methods of Koch? The typical consumptive is a deplorably familiar spectacle. The layman thinks that he can recognize the disease at sight, but let no physician make this mistake.

Of the 1400 patients supposed to be in the advanced stages of pulmonary tuberculosis and sent to the Cook County Hospital for Consumptives from the various hospitals and physicians of Cook county, 120, or 8.5 per cent., have proved, after thorough investigation and prolonged observation, to be non-tuberculous. Some of the mistakes were practically unavoidable and were corrected only on the autopsy table; but in the vast majority of them a negative sputum examination, had it been made, would have led to a more careful physical examination and so revealed the true condition present. Except from a scientific standpoint many of the errors were of small consequence, the patients suffering from conditions even less curable than phthisis. In other cases the faulty diagnosis had deprived the patients of treatment which would have given much relief, if not positive cure.

The difficulty of recognizing incipient phthisis is admitted by all, but are we not too apt to pass lightly over a case presenting marked emaciation, cachexia, cough, hemoptysis, night sweats, with diffuse lung findings, and risk the error of a snap-shot diagnosis? To make a diagnosis of phthisis on the sputum examination alone indicates indolence; to depend on the physical examination without investigating the sputum microscopically shows overconfidence in one's diagnostic ability.

Note the following case:

J. A., Swede, dock laborer, aged 25 years, was admitted May, 1900, having been refused at one of the hospitals in this city because consumptive. Mother died of phthisis. Has been coughing three years, lost 28 pounds in weight; has had pain in chest, occasional night sweats and frequent small hemorrhages; profuse mucopurulent expectoration, loss of appetite, and some diarrhea. Temperature, 98 to 100 F.

Examination showed chest to be symmetrical; no retraction and no bulging; dulness with faint bronchial breathing and coarse râles over entire right lung. Left lung negative except a few scattered râles.

Without examination of the sputum this case might readily have passed for a well-marked tuberculosis of the right lung. However, repeated examinations of the abundant sputum showed the absence of tubercle bacilli, and lead to a more minute examination of the chest. Then it was noted that the dulness of the right lung, while marked throughout, was nearly absolute toward the base, and at times the expiratory sound over the sixth and seventh ribs in the posterior axillary line had an amphoric quality. An exploring needle inserted at this point yielded pus, and rib resection and pneumonotomy, the next day, showed a lung abscess about the size of a small orange situated in the right lower lobe 3 c.m. beneath the pleural surface. The surrounding lung was carnified, and the abscess was draining very imperfectly through a bronchial opening in the upper wall. The incision was enlarged and a drainage tube inserted. The fever, cough and expectoration disappeared very rapidly, but the patient died at the end of a month from general amyloid disease—the result of having been neglected for three years on a mistaken diagnosis of phthisis.

---

* Presented in a Symposium on Tuberculosis, to the [illegible] on Hygiene and Sanitary Science, at the [illegible] of the American Medical Association, [illegible] June 5-8, 1900.

As is well known, there is a certain small number of cases of fibroid phthisis so chronic in their nature as to yield no bacilli even after the most thorough and repeated examination of the sputum. These are readily recognized to be tuberculous by their prompt reaction to tuberculin. The presence of tubercle bacilli in the uncontaminated sputum is recognized as absolute proof of the tuberculous nature of the disease present; the absence of the bacilli does not prove the contrary. In my opinion, the converse is true of the tuberculin test. Reaction following the injection does not *absolutely* prove the presence of tuberculosis; but should reaction fail to follow the injection of so large a dose as 10 m. of a 2 per cent. solution, in my experience tuberculosis is excluded. The frequent occurrence of the so-called "false reaction," especially in syphilitics, has been to me confusing.

A list of the 120 cases mistaken for pulmonary tuberculosis is both interesting and profitable. The diagnosis of aneurysm and endocardial lesions was either made or confirmed by Prof. R. H. Babcock; of progressive pernicious anemia, by Prof. W. A. Evans, and the diagnosis of malignant disease was confirmed postmortem.

The cases consisted of the following: Chronic bronchitis, usually with some complication increasing the anemia and prostration, e. g., exposure, senility, syphilis, gastritis, etc., 45; emphysema, with varying degrees of bronchitis, 12; bronchiectasis, 6; endocarditis—mitral 10, aortic 5, tricuspid 1, total 16; lung abscess, 2; empyema, 6; acute pneumonia (resolving), 6; aortic aneurysm, 3; goiter, 2; syphilis (?)—bronchitis 4, pleura 2, larynx 1, gumma of lung 1, total 8; passive congestion and edema of lungs—from cerebral hemorrhage 1, nephritis 2, cirrhosis of liver 2, total 5; malaria, 2; vicarious menstruation following oophorectomy, 2; secondary sarcoma of lung, 1; sarcoma of mediastinal glands, 1; progressive pernicious anemia, 1 subphrenic abscess following gunshot wound, 1; typhoid convalescence, 1.

THE RIGHT OF THE STATE TO PROVIDE HOSPITALS.*

FINLEY SCRUGGS, LL.B.

MEMBER OF THE CHICAGO BAR.

The paramount object of governments is the protection of their citizens in life, limb, property, and the pursuit of happiness; for this alone the individual pays tribute and renders fealty, and since a diseased person can not have the perfect enjoyment of either, it is manifest that not only does the state possess the inherent right to secure and preserve the health of its inhabitants, but that such is, perhaps, the highest duty it owes them.

The power of the commonwealth to promulgate and enforce sanitary regulations for the prevention and spread of disease, and to establish and maintain hospitals and eleemosynary institutions for the treatment and care of its afflicted citizens, both directly and through the medium of its subsidiary governmental agencies, has been uniformly recognized by law-makers and unequivocally sustained by the judiciary. To show that this is considered one of the most important and vital functions of government, it is only necessary to point to the arbitrary power which the people, in their assembled wisdom, have seen fit to vest in public boards of health, who may prevent the going out or the coming in of the individual, confine him in a hospital and subject him by force to medical treatment; regulate, and even forbid, both the importation and exportation of merchandise; and in the most summary manner may condemn and destroy private property. In the exigent discharge of duty they deprive the citizen of his property and restrain his liberty, without invoking the aid of a court of law or granting a trial by jury—a right which no other power has in times of peace. Their authority seems to cease only at the taking of life.

The duty of the state extends to the adoption of all the means known to science for the prevention, cure, and eradication of dangerous diseases, while its power to do so is limited only by the legislative discretion and the ultimate resources of the community. It is not circumscribed by the treatment of diseases designated as contagious or infectious; in this respect the people have vested in the law-making power a discretion whose only limitations are that the provisions must be made for the public good and for public purposes, and so long as the legislature stays within these bounds their discretion is not subject to review by the judicial department. Some of the American states has gone so far as to undertake the care of inebriates, and have established, wholly or partly at public expense, asylums for their treatment.

It is, therefore, safe to assert that the law-making department of the government may say what disease it is for the public good to check by treatment at the expense of the state. It is undoubtedly not limited to the stage of disease; incipient sufferers may be cared for as well as those physically helpless. There is one limitation dependent on the character of the disease; it is this: that while the state may *forcibly* restrain and commit to a hospital a person afflicted by a contagious or infectious disease, the rights guaranteed the individual by our constitution would be infringed by an *involuntary* commitment when the malady is non-infectious.

It must be borne in mind that hospitals established by the state must be under its supervision, and *should* be open to all its citizens on the same terms; although they *may* be maintained for the indigent only. Taxes can not be legally levied for the purpose of donation to benevolent and charitable societies under the supervision of private individuals, and over which public authorities have no control; but it has been held that a municipality—and of course a state—may pay a part of the expense of a charitable institution, to which it has the right to send its citizens.

I have been asked whether it would be legal for a state to appropriate money for a sanatorium located beyond its territorial limits. A judicial determination of this exact question could not be found in the short time which I have had to devote to this subject. However, it is not easy to conceive a legal obstacle to such an action, provided control of the institution is vested in the officers of the commonwealth, or the right to commit its citizens is preserved. Instances are common of appropriations being made for the display of a state's resources at exhibitions held beyond its limits. If it be legal to spend the people's money to erect a temporary building in a distant community for the purpose of exploiting material wealth, it must certainly be so to build a sanatorium in some more salubrious climate in order that a state may afford its citizens the benefit of necessary hygienic surroundings which it can not give them within its own territory.

---

* Presented in a Symposium on Tuberculosis, to the Section on Hygiene and Sanitary Science, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

A commonwealth may permit the erection within its boundaries of hospitals or sanatoria for patients coming from other states and suffering from such a disease as tuberculosis. It might afterward conclude that such a hospital was dangerous to the community, had become a nuisance, and should be removed, in which event its action in allowing the location would not estop nor militate against it; for the law is, that whatever is in its inception, or afterward becomes, a public nuisance, endangering the public health, may be abated, and the fact that originally it was permitted or licensed by law does not abridge this remedy.

It is apparent that our organic law affords encouragement to the medical fraternity in the performance of the duty they owe to the public of laying before our law-making power the needs of a community measured by a constantly advancing science, and that whether we are to have public institutions devoted to the stamping out of *all* dangerous diseases, depends in great measure on the insistence with which these needs are presented. You should in nowise lose heart because of partial failures in the past, for some of our legislatures may be credited with having done well in this respect on the same principle that Honora Gallagher did well in choosing a husband: for she might have done worse, and, it was said, that if she might have done worse, she did well for a Gallagher.

Marquette Building.

THE TREATMENT OF PULMONARY TUBERCULOSIS.

JOHN M. LISLE, M.D.
COLUMBUS, OHIO.

The most common point of infection in tuberculosis is the mucous membrane of the bronchi and of air passages. It is there that it must be attacked. It does not affect the blood, hence its medication could not interfere with the operations of the germ unless such medication were carried far beyond the ability of the patient to sustain. Stomachic medication is open to the same objection.

The chief reliance of the profession has been cod-liver oil and creosote. The former is a comparatively easily assimilated tissue builder, but is not a remedial agent in any sense of the word. It may temporarily upbuild a patient, but it does not cure because it does not eliminate the bacillus. Having for several years condemned the use of creosote in tuberculous cases, I am glad to note its abandonment by the more observing of the profession, but sorry to see them substituting oil of cloves, an agent equally as irritating and as injurious to digestion.

The effect of creosote on the pancreatic gland, following its use in large doses, is usually the most baleful of its consequences. Unquestionably the pancreatic and the gastric secretions are markedly stimulated in the beginning, and just as the stomach does better work in its peculiar function of digestion, so do the intestines more perfectly perform their duty in the assimilation of the food products reaching them, but the improvement in nutrition by the use of creosote is illusory. Not much time elapses before the pancreatic gland conspicuously ceases to perform its function, and intestinal indigestion, with its train of distressing evils, supervenes. Improvement in this latter respect, however, is the main factor on which the administration of creosote depends for benefit in the treatment of tuberculosis, it being claimed that improvement in nutrition is gained by its exhibition and waste so repaired. Churchill, in his remarks on nutrition and favoring the use of hypophosphites, has recorded his objection to the use of those stimulants, in the exciting sense, to the gastric and pancreatic glands—among which is creosote—and observes that while the immediate results were apparently beneficial, the exaltation in their capacity to secrete and excrete their juices was very temporary and surely followed by an exhaustion from which all means failed to rally.

After years of experience in the treatment of this disease and observing carefully hundreds of persons subjected to the creosote treatment, not a case is recalled which was permanently benefited by its use.

Serum therapy deserves better success than it has attained, and earnest investigators have been striving for years to secure a specific for tuberculosis along this line, but up to the present their efforts have been futile. The hope of the medical profession that ultimate success would crown such well-directed labor has caused them to neglect the more practical channel of the application of specific germicides to the seat of the disease.

Residence in certain climates and travel at home and abroad have long been advised by physicians as beneficial. Elaborate and persistent advertising have made many sections popular as health resorts. They depend entirely upon altitude, proximity of pine forests, the absence of fog, dryness of atmosphere or mineral springs as curative agents. Incipient cases are sometimes benefited in this manner, but it rarely happens that this class of persons consider their condition sufficiently serious to justify attention, while those in the more advanced stages are often permanently injured and their death hastened thereby. At the best, relief is only temporary, unless residence in a suitable climate is permanent, and this generally amounts to banishment from home, friends, associations and business, decidedly otherwise than pleasant to contemplate. The most salubrious atmosphere is not germicidal nor antiseptic, and while the proliferation of the germs may be retarded, they are not eradicated, hence a cure does not result.

The most serious objection, however, to regions supposed to possess advantages of a climatic nature is that they have been visited by so many phthisical persons that they must be hotbeds of infection, if there is any truth in the contagiousness of tuberculosis. The author, in the course of his investigations of this subject, has visited every section of the United States reputed to be desirable as a residence for this class of patients. As a result he has had his opinions as to the meager value of climate confirmed and has been shocked by the prevalence of the disease among natives.

The writer believes in th [illegible] and in i [illegible]
etiologic relation to tuberc [illegible] that th

are germicidal agents capable of destroying the germ or rendering it inert. Physicians believe in aseptic conditions, to obtain which they employ antiseptic agents. Knowledge of the value of antiseptics has become so general that should a physician or surgeon treat either disease or injury without due regard to sepsis or neglect to render the surroundings of his patient aseptic he would be held to be guilty of criminal ignorance or indolence.

That this principle should be applied to the treatment of tuberculosis is not only rational, but, founded on a substantial rather than a hypothetical basis, is in strict harmony with therapeutic law.

By the aid of a suitable culture-medium tubercle bacilli germs can be propagated in sufficient quantity for chemical as well as microscopical study. The germ having been isolated, and its specific pathogenic character demonstrated, the function of the microscopist ceases. It remains for the chemist to determine whether among chemical agents there can be found any capable of destroying it.

Prof. Vaughan, by a series of experiments on guinea-pigs and rabbits, found that animals whose secretions were rendered alkaline previous to inoculation were more susceptible to infection than those in the normal or acid condition. Scientists engaged in the propagation of this particular germ agree that the culture media must be rendered mildly alkaline to secure propagation of the bacillus. From these data I conclude that acid media are inimical to the growth of the bacillus tuberculosis and indicate from what class of agents a bacillicide may be secured.

If bacilli be immersed in a solution of unstable carbon compounds of the aromatic series (type C_6H_6) they will be destroyed in 30 seconds. Bacilli-laden sputum immersed in a 1 to 500 solution is rendered inert in 28 hours. Thus we see that different degrees of strength of the bacillicide solution act with different degrees of intensity.

Given the pathogenic germ, the bacillus tuberculosis, and the chemical composition that will destroy it external to the human body, can we make use of these accepted facts and from them devise ways and means by which the bacillicide can be applied to the area of infection in such potency as to prevent the further proliferation of the germ and render inert those already active? This is a practical question, and can only be answered by a practical test. No theory, however plausible, need be accepted.

The organs of respiration will admit but one element safely. That element is air. The epiglottis instinctively closes upon any attempt to introduce a medicament in the form of a powder or liquid. While it is possible to introduce agents by means of a tube, such agents would only reach the larger bronchi. Access to the smaller bronchi and air vesicles by this method is a physical impossibility. It is possible, on the other hand, to impregnate atmospheric air with germicidal and antiseptic agents, and thereby secure their introduction into the remote recesses of the organs of respiration without effort or inconvenience on the part of the patient.

To efficiently accomplish this, different mechanical appliances will be found necessary. The first in importance is a power air pump of large capacity, by which atmospheric air is forced through a series of cylinders containing the germicidal and antiseptic agents. This process thoroughly impregnates the atmospheric air with the properties of the agents through which it passes. From the impregnating cylinders it must be conveyed through an additional series of cylinders for the purpose of precipitating moisture and thence to the apartment of the patient in quantity sufficient to meet the requirements of the case. Secondly, the apartment occupied by the patient must be supplied with a vaporizer sufficient in capacity to thoroughly saturate the air of the apartment day and night with an aromatic germicidal and antiseptic vapor. The latter appliance is supplemental to the first. Third, a small treatment-room must be provided, in which a very dense vapor can be produced from the agents employed, thus subjecting the patient to a more concentrated action than is practicable in the living and sleeping rooms. This is requisite in acute cases, or where some special complication indicates a greater therapeutic latitude than is available in apartments supplied under the two previous methods.

Bacillicide solutions or vapors sufficiently concentrated to destroy the bacillus immediately upon contact would, at the same time, be incompatible with animal life. I have shown, however, that a greatly attenuated solution is equally destructive of germ life, simply requiring a longer time in which to accomplish its purpose.

To destroy pathogenic germs in an infected house, sulphur is burned or, more recently, it has been ascertained that a pound of formalin vaporized in a room containing 1000 cubic feet will exterminate every disease germ in from one to two hours. This vapor does more than destroy the germs in exposed places—it will thoroughly disinfect a library, effecting the destruction of the germs even though sheltered between the leaves of tightly-closed volumes. Thus we learn that antiseptic vapors and solutions are equally inimical to germ life.

Physiologists tell us that the area of respiratory surface in both lungs amounts to about 1400 square feet, that is to say, a few pounds of tissue is delicately subdivided into a fine membrane richly endowed with blood-vessels, all of which is divinely arranged in the small space of the chest cavity. Remembering this anatomic plan, we have, for purposes of treatment, the lung tissue divided into a microscopic membrane.

By keeping the patient constantly breathing a germicidal and antiseptic air, this microscopic membrane is practically suspended in it and the residual air becomes, and is kept, a germicidal and antiseptic air. This being the case, the entire respiratory surface is rendered aseptic and, therefore, proof against further infection by the bacillus from without as well as from within by caseous or other degeneration of the tubercle.

But rendering the respiratory tract aseptic is only prophylactic. While it prevents further infection and proliferation along this most dangerous channel something more is needed to reach the bacillus intrenched in the tissues. This can only be accomplished by systemic saturation.

When we consider that 1400 square feet of membrane is in continuous contact with the germicidal and antiseptic vapor and that this membrane is not stationary, but with every contraction of the chest walls in the respiratory process the vapor is brought into forced contact with the membrane, we can appreciate, from the law of osmosis and of the diffusion of gases, that a certain, definite quantity is absorbed and the blood more certainly and safely impregnated than would be possible by any other means of administration. Once in the circulation, every cell, not only of the lungs but of every other tissue, except the tubercle tissue, is brought under its influence.

By continuous process of treatment, healthy tissue is kept immunized and further proliferation of the bacilli is impossible. Exception is noted of lack of access to the tubercle tissue where, by reason of its being devoid of vascular supply, the bacilli there encysted are safe from any attack by bacillicides in the form of chemical compounds, antiphthisin, tuberculin or others. Their castle is their own, impregnable to enemies from without, but susceptible to attacks by foes from within. In consequence of having no nutritive supply it is short lived, and this retrograde metamorphosis is hastened by caseous degeneration, a process due to the production of ptomains from the bacilli. The early degeneration of the tubercle exposes the heretofore protected bacilli to the action of the germicidal-antiseptic vapor and those not ejected by expectoration are in an atmosphere antagonistic to the causation by them of further infection. If, however, instead of caseous or other degeneration of the tubercle, fibrosis occurs about the tubercular mass there need be no fear of further proliferation or infection, as bacilli have never been known to penetrate fibroid tissue.

If we can saturate all tissue reached by the circulation of the blood as well as the respiratory surface, we have placed the phthisical patient in the best possible condition for recovery, and all will recover except those in whom the degenerative changes are too extensive to be compatible with the remaining vitality.

That this process does saturate all tissues is evidenced by the condition of the urine and perspiration after ten days' to two weeks' exposure of the patient to treatment. The urine after voiding will remain free from decomposition an indefinite time and it and the perspiration will be found to be laden with the agents employed.

If every case of pulmonary tuberculosis could be brought under thorough germicidal and antiseptic treatment at the time of primary infection no further treatment would be necessary, because the bacilli would be destroyed and the disease arrested before the destructive pathologic changes due to the germ and its secondary toxic property had undermined the nutrition and paralyzed the reactive power of the nerve centers.

The primary action of the bacillus, like any other foreign body, is that of an irritant with the usual histologic changes—exudation of fibrin and leucocytes, epithelial proliferation and interalveolar growth—but with the additional pathologic element, sepsis. This is the result of the presence of a specific toxin, denominated by Vaughan, Bregier, Selmi and others, a ptomain, a putrefactive animal alkaloid, a knowledge of which elucidates many of the distressing symptoms of the disease and constitutes an infallible index to its progression or retrogression.

Few cases being recognized at the time of primary infection, a more extended therapy is required than that comprised in a germicide. The important secondary product of this special pathogenic organism, the ptomain, is subordinate in importance only to the germ itself, but is equally amenable to specific medication by the agents before referred to.

I have stated that a solution composed of unstable carbon compounds has been proved to be destructive to the bacillus and that it might be introduced into the circulation by keeping the volatilized fluid in constant contact with the respiratory surface.

It is a sustained fact that toxic substances readily assume non-toxic form when in contact with substances from which they can appropriate new elements or groups of elements for which they have chemical affinities. Carbon compounds too, readily breaking up when subjected to even weak chemical action, possess marked antiseptic properties.

Further, carbon compounds in breaking up do not resolve into their component elements, but divide into groups of elements to form substances differing in make-up and chemical characteristics from the original types. Bearing in mind the unstable nature of the carbon compounds selected, the facility with which they divide to form new compounds with the products of destructive cell metabolism and the non-toxic character of the new compounds formed, an accurate idea of the theory underlying the method by which we may destroy not only the bacillus, but at the same time neutralize or antidote its toxin, the ptomain, may be readily gained.

I desire to direct particular attention to the salutary influence of the stimulating germicidal-antiseptic vapor on the ulceration consequent on the tubercular process. Every physician has noticed the rapid decline of phthisical patients when large quantities of purulent matter are expectorated—an evidence of extensive ulceration—and felt his inability to control the degenerative physical change. A physician who has had experience with the method of treatment outlined by me must have noticed how speedily the sputum changed from a heavy, purulent to a mucopurulent and, finally, to a mucous character. This change is attained through the combined influence of the local and general antiseptic treatment. By continuous application of the vapor to the surface of the ulcer the same results will be secured as by the application of a stimulating antiseptic to an external ulcer—stimulation, granulation and cicatrization. The ulcerative process peculiar to this disease is of the chronic, indolent variety, hence the benefits derived from a stimulating antiseptic.

Certain clinical manifestations follow the administration of the germicidal-antiseptic vapor as suggested. Within from forty-eight to seventy-two hours there will be improvement in the capillary circulation which is attributable to the stimulating effect upon the vasomotor nerves and the strengthening of the inhibitory nerves of the heart, due to the neutralization of the ptomains. Night sweats, which have been cold and enervating, will become warm and exhilarating and instead of the extremities, the head, neck and chest will sweat most freely. Appetite is restored, a relish for food appears and care must be exercised in many cases, to prevent the eating of more food than can be properly digested. This caution is particularly necessary during the initiatory period of treatment when the patient is closely confined and outdoor exercise limited.

In dealing with a disease of such gravity as [illegible] tuberculosis too much reliance must not be [illegible] aid from one direction alone. It is better [illegible] in the general domain of materia medica [illegible] and hygiene for [illegible] may be of value [illegible] juncts necessary [illegible] the case [illegible] should be [illegible] and [illegible] The best hygienic conditions possible [illegible] the patient [illegible] a nutritious [illegible] and tepid [illegible] baths [illegible] moderate [illegible] their [illegible] and [illegible] pro[illegible] a favorable [illegible]

[illegible] a [illegible]

The broader his professional knowledge, the keener his therapeutical skill, the better will be his results in the use of the method of treatment I have advised.

It has been my practice to restrict patients to their apartments during the first week or two, only permitting absence at meal time and a half hour before and after for exercise.

The object of this restriction is to secure the most complete degree of saturation possible at the earliest period. When there is much elevation of temperature little or no vapor should be employed in the living apartments during that portion of the day when it is at its height, but during the intermission the vapor should be vigorously pushed. In acute general tuberculosis especially, the vapor should be developed to its limit or the patient will perish from toxemia which, by the way, always occurs under any other method of treatment, the patient being overwhelmed by the rapid proliferation of the bacillus and the consequent increased production of its toxin.

It is a matter of common observation that most consumptives suffer, sooner or later, from a persistent, debilitating diarrhea, occasionally caused by indigestion, but more frequently by tubercular infection of the intestines. The patient swallows bacilli-laden sputum which passing along the alimentary canal, finds a denuded mucous membrane, a nidus adapted to its propagation, infection takes place and further proliferation follows. No phthisical patient is wholly exempt from this exhausting and impoverishing complication. I regard it as prudent anticipatory therapeutics to administer an antiseptic solution with a view to the immunization of the alimentary canal against this insidious danger. To accomplish this I administer an antiseptic solution in large quantities of water, not less than a quart in twenty-four hours, and preferably more. In addition, it is desirable that the lower bowel be thoroughly flushed twice weekly, sometimes as often as each alternate day, these enemata being also impregnated with the antiseptic solution. The purpose in using large quantities of water is not so much to provide a vehicle for the antiseptic as to obtain the constitutional effect of the aqueous diluent. When the rapid disintegration of tissue, the consequent amount of effete products and the engorged emunctories are considered, an appreciation is formed of the necessity for a full and free solvent to aid in the elimination of accumulated waste by flushing the sewers of the system. As proof of the value of this precaution not a case of diarrhea has developed among the patients treated after this plan.

As an alterative and for the purpose of supplying to the system those constituent elements of the tissues so rapidly wasted by the process of retrograde metamorphosis I use a tablet composed of the bromid of gold and arsenic and the carbonate and phosphate of lime. They have given the best satisfaction of any combination which I have been able to evolve for the purpose.

Cough is usually one of the most annoying features of this disease, but I have had little occasion for a cough sedative. The specific medication allays excessive irritation, liquefies the exudate and facilitates expectoration without effort. There are isolated cases, however, in which a sedative can be used advantageously. This necessity will arise in the inflammatory stage of the disease when there is a dry, irritating cough accompanied by fever. In these cases I have found nothing equal to the coal-tar products combined with ¼ to ⅛ grain of codeia, preferably administered at the height of the pyrexia. The new product, heroin, prolonging respiration and acting as a quietant to bronchial irritability without depressing effects upon the heart or the central nervous system, may also be used, a convenient form being a 1/12 grain tablet. I am favorably inclined to the liberal use of mild counter-irritants over the seat of tubercular infiltration or consolidation in any stage, but particularly in the inflammatory conditions. When the inflammation is persistent I employ small fly blisters, finding them efficient when milder means disappoint.

Some patients will be more or less disturbed for the first few days by headache and dizziness. In such cases a catarrhal condition of the nasal passages will be found. The local stimulating effect of the germicidal-antiseptic vapor on the inflamed nasal or post-nasal membrane produces this disagreeable sequence. For relief, these cavities should be thoroughly sprayed with an oily mixture two or three times daily until the symptoms subside.

The time required for the realization of the specific value of the vapor treatment varies, in different cases, according to condition, diathesis and susceptibility, the minimum period of subjection being six weeks. Scarcely two persons respond to treatment alike. Some advanced stage cases yield more readily and promptly than those in the earlier stages, but those of the incipient and first stage may reasonably be expected to recover more quickly and with a greater degree of certainty. Marked improvement may be experienced within from four to six weeks, and the progress made during that time will form a safe basis of estimate for the probable necessary period of treatment.

TUBERCULOSIS.

ABSTRACTS FROM THE PROCEEDINGS OF THE CONGRESS FOR THE SUPPRESSION OF TUBERCULOSIS, HELD IN BERLIN, MAY, 1899.[*]

DISTRIBUTION AND IMPORTANCE OF TUBERCULOSIS AS A DISEASE OF THE PEOPLE.

DR. KOEHLER, director of the Imperial Health Office, Berlin—The nature of tuberculosis is such that not all of the cases come under observation in the earlier stages. Therefore, there is necessarily some inaccuracy in the statistics thereof; those for the mortality from the diseases in question are somewhat more accurate. Still, there are misleading factors here. Bronchitis, pneumonia and other intercurrent maladies are frequently charged with deaths that are in reality to be attributed to the "white plague." It causes more deaths than the statistics show, which is especially true in infants. In 20 to 33 1/3 per cent. of all people dying of other diseases, evidence of healed or latent tuberculosis is found post-mortem. In Germany the number of adults over 15 years of age, who seek hospitals by reason of tuberculosis each year amounts to 226,000. It is a disease of all races; Mongolians are subject to it: all the Malay and Negro races have it. Statistics from the United States show that the colored population have double as much consumption as the whites. The death-rate of the City of Mexico and Rio de Janeiro is high, while Buenos Ayres has a small mortality. The British army reports show the following facts. In the East Indies the mortality-rate from tuberculosis is somewhat lower among the natives than among the British troops; among the Europeans it was somewhat lower than among the British soldiers in England. In the West Indies, European soldiers showed a lesser mortality than the non-Europeans. The native troops in West Africa suffered extremely from this disease.

In North America the cities with large ocean-harbors show most tuberculosis, and the western cities least. Melbourne, Australia, does not have much, but Cairo, Egypt, shows a large tuberculosis death-rate; that of Algiers is low. Taking the statistics for phthisis only, the countries of Europe rank in ascending order of prevalence as follows: Great Britain, Norway, Belgium, Italy, Holland, Denmark, Ireland, Switzerland, Germany, Sweden, France, Hungary, Austria, and Russia most of all. Among cities the death-rate from tuberculosis increases as we go along the following list: Buenos Ayres, Naples, London, Amsterdam, Hamburg, Berlin, Warsaw, New York, Rio de Janeiro, Paris, Budapest, Vienna, St. Petersburg and Moscow.

---

[*] Made by W. A. Evans, M.D., Wm. Becker, M.D., and A. Kreikenbaum.

Altitude is probably not of prime importance. The death-rate in mountainous Norway is only a trifle less than that of the lowlands of North-east Prussia and the Netherlands. Alpine Switzerland shows a greater death-rate than ocean-washed England. Comparisons of various portions of Austria and Prussia are confirmatory of this view. Moisture of the air is of great importance. In the north temperate zone, March and April show the largest tuberculosis death-rate; August and September the least.

The statistics of England and of Berlin show that prior to 20 years of age females are more subject than males; at 20 years the rate in men passes that in women. In Berlin the death-rate of tuberculosis is between the ages of 60 and 70. Berlin shows a maximum between 40 and 60; England and Wales, between 35 and 55. In Belgium the maximum years are betweent 15 and 60; in Italy, 20 and 40.

When we inquire what part of the total death-rate is due to tuberculosis in any given year of age we find another series of figures to consider from this standpoint: In Germany the ages 20 to 30 rank first; in England males 20 to 35, females 15 to 25. In Germany of those who die annually between 15 and 60, 87,600 die of tuberculosis, or 300 for each 100,000 inhabitants—one-third of the total death-rate of these ages. These are the years when the citizen is of value to the commonwealth; the loss is incalculable. The hygienic conditions of the cities tend to the spread of tuberculosis, and certain industries are favorable to its dissemination. In the agricultural regions such as East and West Prussia and Pomerania its death-rate is 150; Rhenish Prussia, which is chiefly industrial, shows 290; agricultural Saxony, 190; Westphalia, 310. Beevor's statistics show that the disease can be limited whereever intelligent effort is made.

The following are suggested as proper methods for treatment and prophylaxis:

1. Asylums for the hopelessly sick.
2. Sanatoria for the remediable cases.
3. Disinfection of streets, buildings, public places and public conveyances.
4. Education of the people.
5. Improvement of the general physical tone and stamina.

HEREDITY, PREDISPOSITION AND IMMUNITY.

PROF. F. LOEFFLER, Greifswald—The belief in the inheritance of tuberculosis was general until Koch's discovery. It is now recognized as a strictly infectious disease. In order that the theory of heredity should exist, it is necessary to prove the possibility of transmission of the bacillus from parent to child. Pasteur demonstrated that the silkworm disease could be transmitted from the "fly" through the ovum to the worm. The heredity of syphilis has been proved, and anthrax has been shown to pass from parent to off-spring. If it is possible with these bacteria, why not with tubercle bacilli? An argument in favor of this as a potent possibility is tuberculosis in infants; in inaccessible localities such as bones and joints; in the prominence of tuberculosis about puberty, the explanation being that circumscribed foci of latent tuberculosis had at that season opened up as centers of more general infection. Against this is the fact of the rarity of congenital tuberculosis, the increase of tuberculosis as the age of the individuals increased. If certain families were decimated by tuberculosis, it was because of the greater danger of contagion in such family circles. Johne was the first to demonstrate congenital tuberculosis positively; this was in a calf. Congenital tuberculosis in man and in animals has been proved beyond a doubt. However, congenital tuberculosis only occurs when the maternal parent was affected with advanced tuberculosis to which she succumbed in a short time after the birth of the offspring. Transmission of tuberculosis from the father has never been demonstrated, even when the disease is general or when bacilli are in the spermatic fluid. Tuberculosis is never transmitted through an infected ovum or an infected spermatozoon, but by means of the placental blood. The number of cases of certain congenital tuberculosis is very small. Hauser concludes that, at the highest, 10 per cent. of the babes of mothers suffering from grave general tuberculosis can be reckoned as tuberculous. This percentage is beyond question too high. Consequently, hereditary or congenital tuberculosis has no practical importance.

Many clinicians are of the opinion that a certain susceptibility is inherited from generation to generation, that a bacillus entering such a body would produce the disease, that in this sense tuberculosis was a hereditary disease, and that such a disposition could be recognized by a flat chest, pale transparent skin, narrowing of the arterial system and a degenerative quality of the tissues. There is no doubt that certain abnormal developments of the body and especially of the thorax do increase the liability to tuberculosis. But the fact of descent from tuberculous parents does not per se involve a special susceptibility to tuberculosis. The offspring of artificially tuberculous animals develop just as vigorously as those of healthy animals if they are protected after birth. Bernstein reports a careful study of six cases showing that the cause of tuberculosis in the children of tuberculous mothers is contact and not inheritance. Statistics from sanatoria show that tuberculosis does not run an especially fatal course in patients some of whose ancestors had died of tuberculosis. Turban's statistics show that of those patients whose ancestors had had tuberculosis 49.6 per cent. were cured; of those whose ancestors had had no tuberculosis 44 per cent. were cured. The Davos statistics point out that of those with tuberculosis on the father's side 42 per cent. were cured, with tuberculosis on the mother's side 42 per cent. were cured, with tuberculosis on both sides 60 per cent. were cured; in patients where both parents were themselves tuberculous 50 per cent. were cured. All these observations tend to show that no specific disposition to tuberculosis exists. Clinicians have tried to classify their patients into highly susceptible, moderately susceptible, and insusceptible; but this is entirely arbitrary. The number of bacilli entering the organism is very important; there is another very important factor, viz., the virulence of the bacilli. Vegales procured tubercle bacilli in pure culture from various sources. These were injected into guinea-pigs and rabbits. The disease induced in the guinea-pigs was very uniform in virulence, while in the rabbits there was a great variation. These experiments show conclusively that there is a difference in virulence of bacilli, and it explains the manifold clinical experiences, showing difference in severity and malignancy of tuberculosis.

We will next consider co-called acquired susceptibility or disposition. In my opinion we can not doubt the possibility that after the devitalization of the tissues consequent on many diseases the tubercle bacillus will find it easier to become established; often we can not decide whether the disease is a recent infection or merely an old infection made manifest. It has been stated that certain conditions render a man immune, e. g., kyphosis, emphysema, heart disease, coal-heaving, etc. Consumption is unknown in the dweller in the desert, but whenever he leaves the desert he becomes very susceptible. The racial immunity formerly claimed has not been proved. We therefore do not know of a natural immunity. The question of artificial immunization must soon be solved, by reason of the number of experimenters engaged and the vast amount of experimental work.

The conclusion, since congenital tuberculosis is of no practical importance; since the inheritance of certain devitalizing abnormalities of constitution can not be avoided; since infectious diseases that tend to lower the resisting powers can not be avoided, there remains only one way to combat the disease, namely, the careful destruction of the bacilli wher[illegible] found, and especially in the excretions. [illegible] ses a[illegible] d in sanatoria, incurable cases sho[illegible] ge [illegible] ospitals in order to separate them from the healthy population. Only when the same attention is given to advanced cases as to the beginning ones, can we limit the mighty devastations by tuberculosis.

PROPHYLAXIS OF TUBERCULOSIS IN HOSPITALS.

DR. VON LEUBE, Wuerzburg—Proper prophylatic measures will prevent spreading of tuberculosis in hospitals. These measures are prophylactic and not difficult of execution. In the first place is, the strict enforcement of the rule that patients must always expectorate into cuspidors where bottoms are covered by water. Another important measure is that patients must hold a bunch of cotton before the mouth when coughing. The body and bed linen must be frequently changed and disinfected, and the floor "wiped up." The clothes of the dead must be sterilized or destroyed. Attendants must wear gauze over the mouth whilst in the wards. The patients are to bathe daily. Physicians and attendants must wash their hands in disinfecting solution after each service. Under such proper precautions tuberculous patients can be kept in general wards with reasonable safety. However, it is advisable to put tuberculous patients in a separate consumption ward. This should be the airiest and best in the hospital. It should be provided with verandahs and there should always be resting pavilions on the grounds.

FOOD STUFFS.

DR. RUDOLPH VIRCHOW, Privy Councilor, Medical Councilor, and Professor in Berlin—Every infection must arrive from without, and we necessarily study the routes by which an infection comes to us. We have arrived at the conclusion that tuberculosis is an infection and foods are one of its routes.

The hog is very frequently tuberculous, and has always been under suspicion. Cattle are much more dangerous; under certain conditions, however, the meat from tuberculous cattle can be safely eaten. Even in human pathology the tendency of tuberculosis is to localize itself and leave the balance of the body unaffected. Accordingly, the present German laws allowing the eating of healthy portions of tuberculous cattle satisfy the demands of science.

Milk is of far greater importance, and, likewise, does not always contain tubercle bacilli when the tuberculosis is in regions away from the udder. Hence, there are cattle which have the disease and yet furnish healthy milk. Many years ago I demonstrated that cows with tuberculous udders gave milk that contained tubercle bacilli; this is of the greatest importance, from a dietetic standpoint. The sterilizing of tuberculous milk has value, but it can not always be relied on. The surest procedure is to kill the cows; all other measures are palliative and will be disappointing. I would not urge this point so strongly were it not for my experience with trichina. You know that I led this fight, whilst the meat vendors and consumers opposed it. However, it has been successful and inspection for trichina is now international. I do not hesitate to say that the more I study this question the more I am convinced that we shall find no help other than by slaughtering the diseased animals. In tuberculin we have a diagnostic agent of great value, but even the restrictions that it makes possible are not enough. Every year I see a larger number of representatives elected who are ready to advocate the slaughter of all diseased animals. If you would assist, much more could be accomplished. Hogs should be better inspected; all the diseased ones are, as should be, carefully removed.

No especial restrictions need be placed on the poultry trade. We must do something to prevent so general an infection of the people. Until lately a certain dogma was considered indisputable, namely the dogma of inherited tuberculosis. I now definitely dispute this inheritance. For a number of years I have held that if one examines the bodies of the still-born no tuberculosis can be found; tuberculosis must come from the outside. What shall we do to protect the children? Such prophylaxis must commend itself to mothers, to hospitals and to orphan asylums.

TUBERCULOSIS AND TRAUMATISM: VIRULENCE OF THE BLOOD IN TUBERCULOSIS.

PROF. LANNELONGUE and **PROF. ACHARD**, Paris—Max Schuller pointed out that contusions of joints would result in joint tuberculosis when a patient had general tuberculosis or if tubercular infection was occurring at some point remote from the joint, and that this was true of infections other than those of tuberculosis. Schuller's work was done in 1880 and is therefore questionable.

For this and other reasons, the authors have undertaken some experimental work along this line. They inoculated animals by various routes: subcutaneously, intraperitoneally, by the trachea, and through the blood. The traumatism was sometimes produced before the inoculation, sometimes at the time of the infection, and at other times after varying intervals. The injuries were in the joints, dislocations, epiphyseal separations and fractures. The results were negative in 30 guinea-pigs. In 35 rabbits, 30 showed no tubercular arthritis, 5 did. These 5 were inoculated with large doses of impure products, sputum and tissue intravenously, and the traumatism was made simultaneously. The rabbit is naturally resistant to human tuberculosis, but nevertheless so many bacilli can be introduced into the blood that some can reach the injured tissue in spite of the rapidity with which the blood-cells take them up. This latter observation was made by Borrel. Another factor is, the animal will live long enough to allow the lesions to develop. When traumatism occurs in the course of a slowly evolving tuberculosis, tubercular arthritis does not occur.

Villimen, in 1868, determined that the blood of a cadaver dead of tuberculosis was infectious. In this case the bacilli probably passed into the blood in the agony of death. The blood of six guinea-pigs dead of tuberculosis caused tuberculosis five times when injected into guinea-pigs. Three guinea-pigs having generalized tuberculosis were quickly killed and their blood injected into healthy pigs; no tuberculosis resulted. In the human subject with tuberculosis the blood is seldom virulent; the bacilli seldom get in the blood and never in large number and an area of traumatism has every chance to escape infection. Fractures in consumptives not only do not become tubercular, but healing is not delayed. This is in sharp contrast to syphilis, in which the blood is virulent.

In consumptives subcutaneous injections of sterile liquids do not produce specific nodules. The contrary is true in such infections as staphylococcus, streptococcus, pneumococcus, and typhoid. Subcutaneous injections of sterile solutions—methylen blue, sugar—to the number of 118, did not give one tubercular lesion; abscess followed twice in injections in typhoid, once in pneumonia and once in erysipelas. With a tuberculous man, something more than trauma, however violent, is necessary for tubercular osteitis. The offending influence must be prolonged.

TUBERCULOSIS OF DOMESTIC ANIMALS AND ITS RELATION TO THE SPREAD OF THE DISEASE IN THE HUMAN SUBJECT.

DR. BOLLINGER, Munich—Tuberculosis of cattle and swine is of the utmost importance: 1, Because it is prevalent, 2, because of the danger to the human subject. Tuberculosis of other domestic animals is, practically speaking, of little importance.

Tuberculosis of cattle is characterized by slow progress, slight inclination to acute generalization, by the frequency of nodules on the serous surfaces, the infrequency of cavity formation in the lungs, the relatively slight importance of mixed infection, and by the slight influence on the general nutrition of the animals. As in human tuberculosis, it is difficult to say positively whence and how the infection came; in the majority of instances it can only be guessed at. The milk is a prime factor as a spreader, and the excretions of diseased lungs are also potent.

Statistics show great variance in the prevalence of tuberculosis according to the age and the sex of the animals. Milk cows of mature years furnish much the largest percentages of tuberculous animals. This point is of cardinal importance to man. Statistics for Bavaria in 1895, 1896, 1897 show as follows: tuberculosis in calves, .03 per cent.; in yearlings, 15 per cent.; in bulls and steers, 3.1 per cent.; in oxen, 4 per cent.; in milk cows, 11 per cent. Statistics also demonstrate that tuberculosis among slaughtered grown animals is on the increase. In Baden from 1888 to 1897 the percentage increased from 1.6 to 3.56; in Leipzig from 1888 to 1897 the percentage increased from 11 to 36.8; in Schwerin, from 1886 to 1893, it increased from 10 to 26; in Chemnitz, from 1896 to 1898, percentage increased from 20.8 to 25.2. In middle Europe there was very little bovine tuberculosis up to the middle of this century; rapid increase has taken place in the last twenty years. If we think of it for a minute there is but little difference between the hygienic conditions of stock kept in stalls and men in prisons. According to some observations made at Munich slaughtering house, cattle from the Alps and from the Hungarian steppes show but little of the disease; the Siedenburger cattle show almost none. The Swiss observations are confirmatory.

To the writer's mind the human tuberculosis plays a subordinate rôle in the etiology of bovine tuberculosis. It is more abundant in hogs than it is in cows of the same age. Swine tuberculosis tends to a general spreading throughout the body. It may affect the lungs, the liver or spleen, with or without involvement of the lungs. It seldom tends to cavity or ulcer formation or to invade the pleura or the peritoneum. Glandular involvement is prominent. In the distribution of the lesions it is very closely akin to the same malady in infants. As there are no ulceration processes in the lungs, hogs are less dangerous to their pen-mates than are cattle with the same disease. Nearly all observers agree that in swine it is mostly due to feeding with the milk of tuberculous cows. The etiological relation between tuberculosis of cows and swine is undebatable. Its prevalence in swine is a safe criterion of the danger to the human race from bovine tuberculosis, especially to those who drink milk. In north Germany in 1895 to 1897 from 3 to 6 per cent. of all hogs slaughtered were tuberculous. In Bavaria for the same years the percentage was 2.2. In the last few years, in north Germany, it has been found that of the hogs that were raised on creamery skim-milk, from 60 to 100 per cent. were tuberculous when slaughtered.

It has been proved that the tubercle bacilli can penetrate the mucosa without antecedent or succeeding changes therein. Often there is involvement of the lymph-glands, of the liver, spleen, kidney or lungs without any demonstrable port of entry. The danger from caring for tuberculous animals is small. Of far greater importance is the possibility of direct intestinal infection through milk and meat. This method of infection surely plays a part in the etiology of human tuberculosis. However, it is much less an etiological factor than is inhalation.

Raw or improperly cooked meat that is either infected, or located near or has touched infected organs, is dangerous. This means of infection certainly occurs more frequently than is generally supposed. Meat from a tuberculous animal, in which infection is local or in the initial stage, is not dangerous if the animal appears in good health and the meat has been properly selected and handled. In well-advanced, generalized tuberculosis the meat is beyond doubt pathogenic unless it has been thoroughly cooked. It can be regarded as certain that milk from cows with tuberculous udders is highly dangerous. According to Bang tuberculosis of the udder is present in 1 per cent. of all tuberculous cows. The milk from infected cows with sound udders has been proved to be infective in 50 per cent. of the cases. Not only in general but also in localized tuberculosis in cows with sound udders the milk may be dangerous. All the products of tuberculous milk are infectious. Such milk is especially dangerous if used in large quantities for a long time without being boiled. The danger is increased if this milk is the exclusive diet. Dairy milk, and especially creamery milk, is as a general proposition safer than the milk of a single cow.

Bang, by feeding calves with tuberculous milk, produced a glandular tuberculosis, especially marked in the pharyngeal and mesenteric glands. Bollinger produced experimental tuberculosis in swine 20 years ago, it being most manifest in the mesenteric glands. In 248 tuberculous children Hiller found the mesenteric glands affected in 45.5 per cent. He concluded from this fact that infectious milk plays an important rôle in infants. Lutz showed that 68 per cent. of the tuberculous children treated at the Munich clinic were from non-tubercular parents. He concludes that ingestion and inhalation were the prime etiological factors. The increase in the prevalence of bovine tuberculosis and that of children certainly have some relation. The method of infection in infants, by reason of surveillance to which they are subjected, is much more possible of accurate observation and conclusion that it is in the adult. Tuberculosis in cattle by reason of its great distribution and latent course is very difficult of solution. Without the co-operation of the stock-owner it will be impossible to eradicate it. He must see that it is to his interest as well as to that of the consumer.

Milk should always be boiled. In creameries, only such cows should be used as do not react to tuberculin. Against the danger from milk products, such as butter and cream, we have no adequate means of protection. When we compare the government's effort to suppress tuberculosis with its efforts in other directions, e. g., against cholera, trichinosis, smallpox, adulteration of milk and other foods, we must conclude that all that has been done is in painful disproportion. The most dangerous milk from an infected udder may be sold without molestation, while the comparatively harmless mixing of milk with water is severely punished. Even if tuberculosis of domestic animals is not the most important cause of consumption in man, it is, by reason of its enormous distribution, great increase and etiological relation, the most important of all animal diseases and the most dangerous to man, and it demands the most serious attention.

RELATION BETWEEN ENVIRONMENT AND THE SPREAD OF *TUBERCULOSIS.*

Dr. Krieger, Privy Councilor, Medical Councilor and Medical Reporter in the Ministry for Alsace-Loraine—The great difficulty in determining etiologic factors in this disease is time that elapses between exposure to infection and detection of the disease. All physicians are agreed that wounds or other diminution of vitality of certain tissues, for example, the lung, aid in infection.

There is an uncertainty as to whether there is such a thing as a general increase in the susceptibility. The consideration of statistics is open to two sets of errors; 1, errors in the statistics; 2, errors in the deductions to be drawn therefrom. Statistics show a predominance of the disease in large cities and manufacturing districts. It is found most prevalent among the poor, though occasional statistics have shown a preponderance among certain wealthy people. Poor nutrition is a minor factor in the etiology of tuberculosis. It is more important in therapeutics and in prognosis. A more important factor in causing a lesser amount of tuberculosis among the rich is their better dwellings, less crowding and the comparative isolation of those diseases.

All observations show that the great factor in the spread of tuberculosis is improper handling of the sputum. This reaches a causative maximum in the homes of the poor, the factory, and the workshop. Comparisons show that the curve of tuberculosis ascends with that of density of habitation. In the Imperial Penitentiary at Ensisheim, in Alsace, no new infection with tuberculosis occurs since cleanliness was observed and strict isolation of tuberculous people has been practiced. Now, there is less tuberculosis in this prison than in the neighboring village of Ensisheim.

Collected from a large territory statistics and individual observation teach us that sunlight and air are prime factors in making habitations healthy. There is less tuberculosis in high altitudes. It is only hypothesis as to whether this is due to the effect of the rarified air on the body, or to the thinness of the population and the absence of factories, or to the ease with which these relatively heavy germs settle in thin air, or to the few bacteria of any kind present. Owing to the tardiness with which demonstrable lesions follow infection, statistics on the effect of seasons have slight value

Some occupations furnish i [illegible]
death-rate among sisters of [illegible]

mercy is very great. The statistics of a certain English asylum on this point are of little value, because the changes in the personnel were too frequent. Statistics as to physicians are likewise of little value, because of the transient exposure in their work. German statistics show frequent tuberculosis in nurses and servants in consumption hospitals. Among the Prussian nurses the death-rate from tuberculosis has fallen from 10 per cent. in 1887-88 to 6.7 in 1893-94. This is due to the better use of preventive measures. The great proof of the danger of nursing is in the legions who have contracted tuberculosis from nursing members of their own families.

Dusty occupations make people prone to the disease under consideration. The statistics of Berlin as to street-cleaners, cabmen, coal-workers and miners show this. Farmers have little of this disease in spite of the fact that in winter grain-cleaning is dusty. Metallic dust is most harmful; mineral and vegetable dust less so. Efforts at the suppression of dust in factories, such as the use of fans, exhausts, and wet grinding have decreased the death-rate from tuberculosis. Locksmiths, stonecutters, shoemakers and carpenters are prone to tuberculosis, because their customary bent attitude prevents proper pulmonary inspiration and expiration. This is also true of tailors.

Beneke determined that the lungs of consumptives are large and their hearts small. The average relation in consumptives was 12 to 1. In patients with cancer 6 to 1.

SERUM DIAGNOSIS OF TUBERCULOSIS.

PROF. S. ARLOING and DR. P. COURMONT, Lyons—We have written on this subject, setting forth most of the following facts, for the Academy of Sciences in 1898, and for the Paris Tuberculosis Congress in 1899.

1. *How to Obtain Homogeneous Cultures of Tubercle Bacillus in Liquid Media*—It is possible to make Koch's bacillus grow in various liquid media, especially glycerinated media in a homogeneous fashion. Such cultures show an even turbidity, with the bacilli isolated. The bacilli have slight mobility. The principle necessity is daily agitation of the culture. A culture which has acquired this new appearance in bouillon will speedily return to its old type if allowed to age or if it is not shaken daily. On the other hand, after a few generations, the new characteristics become fairly well fixed. When such bouillon cultures, with the new type fixed, are planted on glycerin-agar, at the end of a few days we get a creamy smooth layer rather than the wind-row arrangement that is usual. Such cultures lose their staining peculiarities, and are easily decolorized by acids. It is very necessary to grow the cultures exactly right in order to get reliable results.

2. *Obtaining Proper Cultures*—The best medium is beef or veal bouillon containing 1 to 2 per cent. peptone and 6 per cent. glycerin. The cultures must be agitated at least once a day. Cylindrical flasks with flat bottoms are preferable. Such bouillon is inoculated with a definite quantity of a vigorous culture one month old. The tests are made with bouillon cultures eight to twelve days old.

3. *Technique.*—Certain precautions, not required for typhoid tests, are necessary here. The "loop" must be taken from the upper part of the culture. Serum is preferable to the entire blood; uncolored serum is better than that containing hemoglobin, and fresh serum should be used rather than that which is old. The serum is obtained by allowing the clot to retract, or by centrifuging. We mix three lots of serum in the following proportions: One drop of serum to five of culture; one to ten; and one to twenty. The mixture is drawn into tubes of small lumen, inclined at an angle of 45 degrees, and allowed to stand from two to twenty-four hours. Examination is made with the naked eye and with the microscope. To the naked eye the mixture is clear; the bacilli are along the glass, mostly at the bottom. Examine at the end of two hours and again at the end of twenty-four. Have an unmixed culture similarly arranged for purposes of comparison. Now, carefully take a drop of the serum mixture from near the zone of precipitated culture and make a microscopic preparation. Compare with a slide of an untreated culture. It is advisable to keep some serum from a tubercular pleurisy or peritonitis always on hand to act as a check on your tests.

4. *Artificial Production of Agglutinating Power*—The authors produced this agglutinating power in serum of dogs, goats and guinea-pigs by inoculating them with mild cultures of tubercle bacilli. Virulent cultures producing exudative forms of tuberculosis did not give this modification of the blood-serum.

5. *Clinical Application*—All of the precautions enumerated above are absolutely necessary. Our studies have been going on since May, 1898, and they extend over two hundred patients who were tuberculous, otherwise diseased, and healthy.

The agglutinating power of blood-serum was tried on 186 patients. Of these, 128 gave a positive reaction, 69 per cent.; 58 gave no reaction, 31 per cent.; of these 128, 96 were proved to have tuberculosis by physical examination, sputum examination, or autopsy, 75 per cent; and 32 gave no evidence of tuberculosis other than this agglutination, 25 per cent. Of the 58 cases giving no reaction, 10 were otherwise proved tuberculous, 17 per cent., and 48 gave no sign of tuberculosis, 83 per cent. Of the 106 certainly tuberculous 91 per cent. reacted; 9 per cent. gave no reaction. The 96 reacting cases showed all degrees of the disease. Of the 10 not reacting 7 were most advanced cases. The milder cases react best. Of the 60 clinically non-tuberculous patients, but having various other diseases, 26, or 43 per cent., reacted; 34, or 57 per cent., did not react. Of these 26 reacting cases, autopsies were held on 20. Of these, 20, 9 had latent or cured tuberculosis, 45 per cent. The reaction in clinically non-tuberculous cases probably indicates latent tuberculosis.

Comparison is made with the statistics of Beck as to the reliability of tuberculin as a diagnostic agent. Beck found that 60.8 per cent. of all sick people, tuberculous and otherwise, responded to tuberculin. Our similar serum trial showed that 69 per cent. responded. Beck examined 371 clinically tuberculous patients: 100 per cent. responded to tuberculin. Of our clinically tuberculous cases 91 per cent. responded to the serum-test. Beck examined 2137 clinically non-tuberculous sick people; 1194, or 54 per cent., responded to tuberculin. Among our similar cases 43 per cent. responded to serum.

Differences in the patients examined are responsible for the differences in the figures; the results are, in the main, strongly corroborative. The advantages of the serum method are: 1, its harmlessness; 2, facility and rapidity; 3, delicacy. Its disadvantage is the number of necessary precautions.

6. *Agglutinating Power of Serums from Tubercular Cavities, e. g., Serum from Tuberculous Pleurisy.*—The results given here are even more accurate than in the use of blood-serum.

General Conclusions.—The use of homogeneous bouillon cultures permits us to use serum diagnosis in tuberculosis. The use of proper technique is imperative. In men the agglutinating doses are from 1 to 5 to 1 to 20. The results of 186 examinations show the test to be valuable. Its results run very nearly parallel with those given by tuberculin. It is especially valuable in cases of latent tuberculosis. It is most valuable in diagnosis of early tuberculosis and least valuable in late, extensive or exudative tuberculosis.

MIXED INFECTION IN TUBERCULOSIS.

R. PFEIFFER, Berlin—The clinical course and the anatomical and histological findings in tuberculosis are irreconcilable with the effects of the tubercle bacillus. Hence, Koch looked for other organisms in tuberculosis besides the tubercle bacillus. He found micrococcus tetragenus, bacillus pyocyaneus and various cocci. He wrote that these organisms were probably benign in lung cavities, or else that they took part in the destruction of tubercle bacilli. The term "mixed infection" was first used by Brieger and Ehrlich in 1884. The term should only be used when two distinct organisms infect a body entirely independently of each other. The infection, by other germs, of lungs already tubercular should be spoken of as secondary infection, as suggested by Petruschky. However, the terms are habitually used synonymously, and I do the same here.

The following have done valuable work on this subject: Babes, Pausini, Cornet, Petruschky, Spengler, Ortner, Ehret and Schuetz. In 1890 Pausini isolated 24 varieties of organisms in tubercular sputum; his technique was faulty. Koch's method is the proper one: Wash the sputum in many changes of sterile water until nothing remains but the central "core," which, beyond question, came from the tubercular area.

In this central "core" streptococcus is often found, sometimes alone. Less often staphylococcus, diplococcus lanceolatus, bacillus pyocyaneus, Friedlaender's bacillus and micrococcus tetragenus are found. During influenza epidemics enormous numbers of influenza bacilli are found. Ehret and Schuetz have lately added pseudo-diphtheria and true diphtheria bacilli to this list. Streptococci usually predominate. The most frequent combinations are streptococci and staphylococci, streptococci and bacillus pyocyaneus, streptococci and diphtheria bacilli, and streptococci and diplococcus lanceolatus. The organisms causing the secondary infections are found in the tissue as well as in the sputum. Cornet called attention to the fact that in the same lung one cavity might show nothing but tubercle bacilli, another a mixed infection of one kind, and another a mixed infection of a different kind. Ortner studied the tissues in 61 cases of pulmonary phthisis. He studied the bronchopneumonic areas surrounding the clearly tubercular areas. In 28 of 42 cases he found a modified streptococcus present, this he called micrococcus pneumoniæ. Cornet, Petruschky and Spengler verified this work and showed that this coccus was nothing but streptococcus. Micrococcus tetragenus was also found in the tissue. Pfeiffer showed that the lobulocellular infiltrations surrounding the tubercular areas, and found so typically in influenza epidemics, were due to influenza bacillus. Schuetz showed the diphtheria bacillus in the tissue.

Petruschky found that streptococci present in the exudative areas of tubercular lungs had lost most of their pathogenic power for animals. But these slightly virulent cocci might be very pathogenic in lungs of lowered vitality and in cavities of varying hydrostatic pressure. Again, the usually slow course of phthisis shows that none of the organisms can be of great virulence.

A. Fraenkel described a caseous bronchopneumonia due to tubercle bacilli alone. This does not alter the importance of mixed infection very much. Baemuler described certain cases of tuberculosis that progressed slowly up to a certain point; then spread rapidly, just subsequent to hemorrhage. He thought this rapid spread due to inspiration of blood laden with tubercle bacilli and other organisms.

How do secondary bacteria get into the lungs? If Druick was right when he said that various pathogenic bacteria are always present everywhere in normal lungs, then the question is easy. Besser, Klipstein, Hildebrandt and Mueller proved that normal lung tissue and the mucous lining of the smaller bronchioles are always sterile. Even then the contents of the upper air-passages and the surrounding atmosphere are dangerous.

We agree with Struempell that clinically the most important symptom of mixed infection is fever. Fever is always a bad indication, its absence is a good one. Bacillus tuberculosis alone can produce fever; as a rule it does not. The characteristic fever, chill and sweat of phthisis is due to secondary infection. Petruschky says of streptococcus infection: "Suspicion of secondary infection is proper in remittents, intermittents, and in those cases which are subnormal in the morning and reach 38 C.—100.4 F.—in the afternoon."

As a rule the blood of tubercular patients is sterile during life. Petruschky has shown that streptococci can be found in 50 per cent. of the cases of phthisis if the heart's blood be examined post-mortem, but this is due to infection during the article of death.

Examination of the sputum in unmixed infections shows a small quantity and a few tubercle bacilli. Examination of the sputum in mixed infections shows much sputum, many secondary bacteria and sometimes no tubercle bacilli. Petruschky and Spengler sometimes found streptococci in the sputum of afebrile cases. This was exceptional. Here the organisms were in the cavities, not in the tissues. The importance of secondary infections has been determined in tuberculosis of the bones, the joints, the larnyx, and the skin. We can be certain that the prognosis is made worse by secondary infection. The physician must aim to avoid such complication.

TREATMENT OF TUBERCULOSIS WITH SERUMS.

Dr. E. A. de Schweinitz, Washington, D. C.—In 1894 I published a series of experiments in which guinea-pigs were immunized against tuberculosis by injecting them with cultures of tubercle bacilli that had been weakened by years of growth on acid media. This work was verified by Trudeau. With this view I have tried to get a serum from horses, mules, etc. I use an extract of the bacilli that float on the surface of cultures. This is injected in horses for several months. Now the serum is drawn. This serum was tried on guinea-pigs previously inoculated with virulent tubercle bacilli. The guinea-pigs recovered.

Dr. Stubbert, of the Loomis Sanitarium, at Liberty, New York, used my serum for 1½ years, during which time 90 patients were treated with the following results: 19 per cent. were totally cured; 7 per cent. considerably improved; 57 per cent. somewhat improved; 17 per cent. not improved. The improved numbered 75, unchanged 8, and 7 were aggravated. Of the 90 patients 42 were in the early stage, 44 little advanced, and 4 were advanced cases.

Expectoration was diminished in 774, and remained unchanged in 16; cough diminished in 72, and was unchanged in 18; appetite increased in 74, and was unchanged in 16; weight increased in 69, was unchanged in 14, and decreased in 7.

Temperature decreased in 44 and was unchanged in 46; tubercle bacilli were always absent in 11, disappeared in 11, diminished in 32, and remained unchanged in 36.

From these results and my own I am justified in claiming that tuberculosis can be markedly improved and frequently cured with my serum. The pathogenesis of tubercle bacilli may be in some way related to the large amount of fat that they contain. I take cognizance of this in preparing this serum. The production of a tuberculosis serum should be exclusively in the hands of the state for a number of years.

I suggest an international committee on treatment of tuberculosis whose business it would be, to investigate remedial efforts against tuberculosis and let the world know the results of such investigations.

Homicide by Carbolic Acid.

A case of some interest was recently before a coroner's and magistrate's court in Toronto, which brought forward the question of homicide by carbolic acid. A citizen was dead on the arrival of a physician who had been summoned hastily. Although four physicians saw the patient in rapid succession, none of them detected the odor of carbolic acid in the room or about the person of deceased. The coroner was notified, and on a post-mortem examination, carbolic acid was found to be the cause of death. Suspicion rested on his supposed wife and a young man who was boarding with them, and their arrest followed, with a charge of murder. No bottle was found which had contained carbolic acid, in the room, and it could not be ascertained where the deceased had got the drug, nor if either of the accused had purchased it. The crown became possessed of the idea that the victim had been administered carbolic acid for a length of time, and the officers of the crown endeavored to prove that such could be possible and that carbolic acid could be administered in some other substance which would disguise its peculiar odor and taste. After dragging along for six weeks, the coroner's court brought in a verdict that the deceased had come to his death by carbolic acid, by other than his own hand. The case was then brought into the police magistrate's court, where it was at once summarily dismissed, and the prisoners liberated. The case, however, brings up two interesting features: Can there be such a thing as poisoning by carbolic acid administered internally, chronic in form, similar to chronic arsenical poinoning for example; and could carbolic acid be given any one in such a form, the odor and taste so disguised, that the person to whom it was given would not know what he was taking?

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

SATURDAY, OCTOBER 20, 1900.

TUBERCULOSIS.

The present issue of The Journal is devoted mainly to the subject of pulmonary tuberculosis, the one disease that is just now foremost among subjects of medical discussion. Probably nothing has stirred up the medical profession at any time during the past century as has Koch's discovery of the tubercle bacillus. The disease we have had always with us and the suspicion of its communicability was not new, but this scientific confirmation of the facts and the practical deductions therefrom have amply warranted enthusiasm. We know now that tuberculosis, which is responsible for so large a proportion of human mortality, is an infectious disorder, and what is still more valuable knowledge, that it can be recognized in its early stages while still curable and that it is to a certain extent preventable. It is natural that, under these circumstances, enthusiasm should be aroused and sometimes extravagance be indulged in even by medical men in their estimation of the dangers of infection. Very little, however, if any, of this tendency will be met with in the papers in this issue.

There are yet many points to be cleared up in regard to tuberculosis, and it may be that some of our present views as to its mode of infection may have to be modified in some respects, but it can safely be said that the papers in this issue fairly represent the present consensus of opinion in regard to it. The more hopeful views of the disease are gaining ground and it is possible that in the future more stress will be laid on constitutional and environmental and less on the bacteriologic factors in its etiology. If we are to accept the statements and views of some modern writers as to the prevalence of cured and latent or quiescent phthisis we must admit that the bacillus tuberculosis is not as dangerous an organism as it has come to be believed by the public, and our efforts directed to strengthen resistance must be generally considered as of more importance than those aimed at merely restricting the infection. One thing seems reasonably certain; pulmonary consumption is, at least locally, on the decrease. This is shown by Dr. Hinsdale's paper in this number, in which he reports a decrease of the percentage of deaths from pulmonary tuberculosis to all deaths in the city of Philadelphia from 14 to 10 per cent. in fifteen years. Other cities, such as Berlin, where statistics are reliable, show a similar decrease, and in spite of possible criticisms, it must be admitted that the registrar-general's statistics for Great Britain give similar testimony. It should be remembered in this connection that with a decrease in the general death-rate there might very easily be a proportionate increase in that from consumption, with an actual decrease. But both the actual and the relative mortality are reduced.

There is much yet to do before consumption ceases to be the "great white plague," the one pre-eminent scourge, but the outlook is now more hopeful than ever before. The public has already received rudimentary education on the subject—a little one-sided perhaps in some regards, but nevertheless one on which to build a more complete and perfect body of information. The occasional, somewhat too hysterical manifestations of some of the antituberculosis agitation are only a temporary phase of the progress toward the desired end—the restriction if not the eradication of the disease among men.

HOSPITAL TREATMENT OF TUBERCULOSIS.

The number of hospitals for tuberculosis is increasing rapidly, not only abroad but in this country. In places where special hospitals have not been possible, wards or wings of general hospitals have been set aside for tuberculous patients. While a special hospital is certainly best, it is unquestionably true, that special wards are better than general mixing of patients. It seems to be true that infection with tuberculosis is much more apt to occur where contact is continuous than where it is casual.

In order to get the best, or even satisfactory results from hospitals, it is necessary to specialize. There should be hospitals for advanced cases of tuberculosis, and others for the cases that promise more from treatment. The question arises: Why should we erect hospitals for the hopelessly sick? The good that they do can not be shown by statistics. The patients usually come from crowded homes and insanitary surroundings. They often come from bedrooms occupied by several people. They pass the day-hours in yards or work places where there is little sunshine and much moisture. Such a patient at home is a constant menace to his family and source of some danger to others. This is the great good that these hospitals accomplish. There are lesser benefits. Many people remain in a hospital a short time and return to their friends. If they remain even a short time they are taught the care of the sputum, the necessity for sunlight and general hygiene, and much good for the community has been accomplished. The cures in a large hospital will never be very much of a factor. Even when cured, the patients will seldom get on such a physical plane as will make them useful to their families or to society.

The second class of hospitals for tuberculosis is the sanatorium for the incipient-stage group. Many hospitals concentrate their efforts as much as possible on those cases of tuberculosis that can be cured and restored to usefulness. Several of the articles in this symposium and the accumulated experiences of hospitals in many countries show that from 25 to 60 per cent. of people with tuberculosis who are properly treated are cured. When cured, they are strong enough to take their places among the bread-winners or the home-makers.

While the climate of the West and of the mountain districts of the East is especially beneficial, the possibilities of sanatoria are not limited to those districts. Sanatoria in those regions that are supposed to be unfavorable for the cure of tuberculosis show an excellent percentage of recoveries. Porches, verandas, windshields, solariums, etc., can in a great measure replace the conditions found in more favored locations. Some of these hospitals have been built by states or municipalities, some by private charity, and others as business propositions. Each source is legitimate and proper. The duty of the state to cure where it can is no less urgent than it is to care for those that are helpless. The article by Mr. Scruggs covers the point of right, though it is clear that a state has the right to do whatever is its duty.

Unquestionably hospitals will be built on the lines advocated by Dr. Oliver, namely, small hospitals for small communities—serving as sanitary homes for those having tuberculosis to an incurable degree, and being havens of hope for others.

HOME TREATMENT OF TUBERCULOSIS.

The profession is to be congratulated on the progress made in the study of tuberculosis during the last few years. Through better knowledge of the subject, more people recover from the disease, an earlier diagnosis is made in many cases, and a more rational care of the patients has come about. The modern sanatorium management too, we may well believe, offers the best chances for recovery and is destined to still further reduce the general mortality.

But most patients are unable to pay for institution treatment and the state can never hope to provide sanatoria for half of the indigent cases, even if they were all willing to go to them, which is not the case. There will always be a large number of people who will sicken with consumption and recover or die from it at home. These must depend, in the main, on the assistance of their family physicians. Are these physicians doing as well as they can for such cases? Are such cases having as good a chance for their lives as their circumstances and surroundings make possible? We think it is only fair to answer each of these questions in the negative. Physicians are too often careless as to details of hygienic management, on which the life or death of the patient depends. Some seem never to have learned that benefit can come of such measures. Most such patients have no carefully ordered hygienic management, except that which they devise themselves. They are given medicines, usually tonics, such as strychnin, iron, quinin, cod-liver oil and whiskey, all of which in their way are beneficial. They are admonished to eat and to cut down or stop their work, both of which they do in a most empirical and unscientific way. Every patient ought to receive from his physician a carefully prepared schedule of regimen, written out minutely if need be, and to be observed continuously. It should cover all details as to the number of hours daily to rest, and how to do it; the methods of rest out of doors; the kind of room and bed to sleep in; the ventilation for both night and day; the character and amount of exercise; the way to be clothed; the food for each meal, and the number of meals each day —more than three—and the hours they are to be eaten; the care of the stomach and bowels; and the management of amusement for mental tranquillity.

How many cases in a hundred ever have such attention? Yet the life of many a consumptive depends on avoiding some indiscretion which such rigid rules might prevent, and it is attention to just such details as these that makes the remarkable records of the sanatoria. Is it impossible to give the average case some fair approach to such efficient services at home? We prefer not to believe it. The people are ignorant and not to blame if they fail. The physician knows the value of these measures and is responsible. He ought not to evade his responsibility. The home treatment of pulmonary tuberculosis is, we believe, not half as effective as it might be made, and ought to be.

COCAINIZATION OF THE SPINAL CORD.

Although but little more than a year has elapsed since Bier presented his first article on cocainization of the spinal cord as a means of inducing anesthesia for surgical purposes, he has also deemed it necessary to warn against the too free use of the drug in this manner.[1]

He considers the dose of [illegible] cgs. to 5 cgs. which has been used, as dangerous and says the dose should [illegible] exceed 15 mgs. He holds the problem [illegible] cocain in the manner which he first described [illegible] which he predicts [illegible] of rendering [illegible] ant after-effects [illegible] He has been [illegible] along these lines [illegible] cess, but [illegible] these experiments [illegible] cluded [illegible]

[illegible]

---

[1] [illegible]

a lumbar puncture, as the solution must not be injected until clear cerebrospinal fluid is seen to escape from the needle. While lumbar puncture is ordinarily a simple and safe procedure, it is not always so, as Gumprecht[2] reports 17 cases of sudden death following simple lumbar puncture for diagnostic purposes. The toxic properties of cocain, when injected elsewhere in the body, are well known, and Bergmann[3] reports a case of the most acute poisoning following the injection of 3 cgs. into the calf of the leg in a man in whom the day before he had injected 5 cgs. into the gluteal region without perceptible symptoms. As a rule, intoxication symptoms follow the injection of cocain into the subarachnoid space. While these symptoms are usually mild and evanescent, they are not always so. Racoviceanu Pitesti[4] reports 125 cases with the following results: In 4 cases anesthesia failed and he was obliged to resort to chloroform; in 2 cases anesthesia ceased before the operation was finished; of the first 100 cases, 17 showed no disturbance; 80 had light intoxication symptoms lasting from twelve hours to five days, while in 3 the intoxication was so severe that life was in great danger. He considers the presence of kidney disease a contraindication and that patients with heart disease and arteriosclerosis require close watching. He concluded that the methods can not take the place of chloroform or ether, on account of its many inconveniences and the inconstancy of the solution.

Tuffier[5] in 125 cases had 5 deaths, 4 of which could not be referred to the anesthetic; the fifth, however, died with symptoms of asphyxia. The autopsy showed mitral insufficiency and two fresh lung emboli. He says the method should not be used in children nor in the hysterical.

It is apparent from these facts that the method is not free from danger, and should be used only with the greatest caution and attention to detail. It would also seem advisable that the indications and contraindications should be more definitely determined and the problems pointed out by Bier be solved by those in position to do so before the method be generally adopted by the profession.

THE HALL OF FAME.

The Hall of Fame, which is to be the American Westminster Abbey, has received its first score and a half of inmates by the suffrages of the 100 judges selected from among college presidents and jurists. The results thus far are interesting in several points of view. There is hardly anyone whose opinion is worth anything who will not, in view of the names selected from and those selected, find something to criticise. As physicians we have a grievance in that, while several eminent men had been suggested, not one of our profession was deemed worthy of a place in this Walhalla. The statement is made on good authority that this is due to the light vote cast for any physician by the chief justices on the jury, and the fact is a commentary on the plan of giving such matters to the decision of members of an elective judiciary. The vote is, we understand, to be published in full detail, and its study will undoubtedly afford much food for reflection.

DILATATION OF STOMACH DUE TO COMPRESSION OF DUODENO-JEJUNAL JUNCTION BY MESENTERIC ARTERY, VEIN AND NERVE.

A writer in the *American Practitioner and News* for August, 1900, calls attention to a cause of dilatation of the stomach in visceral ptosis by pressure on the duodenum by the superior mesenteric artery, vein and nerve. He claims to have studied the subject for several years and the paper is illustrated with diagrams and sketches intended to make clear the mechanism. As he found no records in the literature showing that dilatation of the stomach may be caused in this way, he considers his observations as original. There is no occasion to doubt the author's claim that his observations are original in so far as they were made without previous knowledge of similar observations being recorded in medical literature, but his investigations into the literature must have been exceedingly superficial and limited. The subject is dealt with in an editorial abstract in THE JOURNAL xxxiii, p. 487, based on an article by P. A. Albrecht, which appeared in *Virchow's Archiv*, clvi. In this article Albrecht describes two striking and fatal instances of this form of obstruction and refers to similar observations by Glenard, Kundrat and Schnitzler.

DISEMBODIED PRACTITIONERS.

In the State of Massachusetts a medical-practice act, rigid in other respects, exempts from its provisions clairvoyants, mental healers, magnetic healers and those that practice the curing of diseases by the use of hypnotism. In other words, the greater the humbug the greater is the privilege, while any pretense to accurate knowledge must be rigorously investigated. It would seem that the lawmakers reasoned that since a little knowledge was a dangerous thing, absolute ignorance must be safe, a fallacy the more readily adopted since it is a natural tendency of human imbecility to love to be humbugged, as that eminent student of human nature, P. T. Barnum, expressed it. Like the silversmiths of Ephesus, the Massachusetts legislators may also have had self-interest in mind, for does not the great goddess of "Christian Science" reside among them, at least part of the time? In a recent lawsuit it was held that bills for medical treatment by spirits could be legally collected by the individuals through whom these disembodied practitioners acted. No question appears to have been asked as to the qualifications of these ghosts, though the plaintiff only claimed to act as their instrument. Whether such temporary inspiration can properly be accepted under the law, as it appears to have been in this case, may be open to question; at any rate, there is a chance for an interesting legal quibble. If a man is not really himself, or claims not to be, when under such influence, has he the right to practice in the name of another whether that other be living or dead?

Leaving such matters aside, however, it seems a pity that the laws in the region that popularly passes as the center of culture of this continent should be restrictive only on those that have some pretense to qualifications and should offer such premiums to ignorance and superstition.

ALLEGED INSANITY IN THE ARMY ABROAD.

According to some of the sensational journals of the day, it would appear that the American army serving in the Orient was being decimated—if that is the word—by mental disorders. Thrilling statements as to the effects of climate and homesickness have been sent abroad and it would seem quite possible that they have caused serious distress to friends and some concern to well-wishers of our soldiers generally. According to a Washington dispatch, this anxiety is altogether needless. From reports received by the surgeon-general of the army, there have been only 84 cases of insanity last year among the troops in the Philippines, though from newspaper accounts there ought to have been ten times as many. There were, it is said, only 188 cases altogether in the whole army of over 100,000 men, which gives fully as favorable a percentage as we have in any class of our population. Moreover, half of these cases were only temporary results of nostalgia which were quickly recovered from, the most then returning to duty. A specially favorable fact is that the number of cases attributed to intemperance was very small; this has a bearing also on another frequently repeated scandal. These facts are given out in advance of Surgeon-General Sternberg's report, which, it is said, discusses the subject somewhat fully. We see no reason to doubt their reliability.

THE REVIEWING OF BOOKS.

A majority of the book reviews nowadays are favorable. This has led to the statement that literary magazines are "publishers' organs." To this charge the *Chicago Sunday Tribune* for September 30 makes answer. It admits the truth of the statement in the opening line. "The contrast with the slashing of the *Edinburgh Review* is indeed marked, but it by no means follows that the book reviews of the present time are any more a failure than those which flayed Shelley or drove Keats to an early grave." The conditions in the book market are such that but a fraction of the books published can be reviewed, and hence the tendency to select for review chiefly the books worthy of praise, the inferior productions simply being ignored. And then personal animosity and political prejudice no longer play any such part in the reviewing of books as they did a century ago—and this is certainly right. For these two reasons the *Tribune* considers a return to the older methods of "slashing criticism" as undesirable. The conditions in medical literature are not unlike those in the literary world at large. The great number of medical books now issued practically preclude critical reviews of all. Time and space are too valuable to be wasted in giving detailed and critical examinations of all the publications placed on the editor's table; the majority of which are of an elementary and ephemeral nature, not altogether worthless, perhaps, but surely not of such character as to produce any impression on the development of medical science. Many medical periodicals have adopted the policy of acknowledging all books received, selecting only the more important for review. It is natural that under these circumstances the majority of reviews are of a commendable tone. Yet these journals are not, therefore, "publishers'" or "house organs." Let the very fact that a book is chosen for review mark it as one of considerable importance! The standard of the review columns in medical journals should be so high that an author would feel honored when his book is dignified by being reviewed. Reviews of this sort need not be of unreserved praise; dignified criticism is always desirable when offered by competent reviewers in true scientific spirit. "Roasts," on the other hand, are productive of unnecessary ill-feeling, even when bestowed on worthless books that had better be left entirely unnoticed. Managed in this manner, the book departments of medical journals would soon rise to something more than gratuitous advertisements of recent publications without discriminating between the worthy and the insignificant.

SOME STATISTICS OF INSANITY.

A recent study of the statistics of the Hudson River State Hospital for the Insane, by Dr. Charles W. Pilgrim,[1] though covering but a comparatively limited number of cases, presents some features of interest. In the first place, it seems to show that modern methods are productive of better results in the care and cure of the insane than those in the past. From the opening of the institution in 1871 until 1896, a period of twenty-five years, the average recovery-rate was about 21 per cent. on the admissions, and those discharged improved, 11.5 per cent., while, making all due allowances for earlier unfavorable conditions such as the larger proportion of chronic cases transferred to a new institution, the present total exceeds the above average by at least 9 per cent. This, it should be remembered, is an estimate made with the modern conservatism in estimating recoveries, for the old fashion of counting every lucid interval a recovery has of late years been replaced by an extreme caution in this respect. Many of the patients discharged as improved would have been counted without hesitation as recoveries in former years. Another point of interest in this connection is that these statistics support the hopeful view that bad as the outlook usually may be, yet while there is life there is hope in all insanities where there is not indisputable evidence of profound damage to the brain. Eight out of the year's recoveries had been insane for two to five years before reception, and nine had been inmates for like periods. Such facts, and they are frequent in asylum experience, indicate that even chronic insanity may yield to modern methods. An analysis is made by Dr. Pilgrim of the data as to the hour of death, a subject of possibly more popular than scientific interest, but one that is nevertheless worthy of study if only because of the popular beliefs. Dr. Pilgrim found that the most fatal hours of the day were between noon and 6 p.m., 31 per cent. of all deaths occurring within this period. In fact, the highest point of the death-rate in the statistics of the last decade was reached between the hours of 3 to 6 p.m.; the next highest point was between the hours of 3 and 6 a.m., though this was affected by a decided fall between the hours of 4 and 5 a.m., when it went down to the lowest figure in the whole twenty-four hours. These figures therefore show, as Dr. Pilgrim says, "that there is some reason for the popular belief that many deaths occur during the early morning hours, but they show still more plainly that the majority of those who suffer from long-continued mental disease give up their lives toward the close of the day." Still another point noted by Pilgrim, which bears out a popular belief, is that of the return of mental lucidity at or a little before the moment of death. He finds this true in many cases, especially in the insane dying from phthisis or acute intercurrent diseases or injuries that produce a profound shock on the general system. This fact has been often noticed, but, as he says, little has been written in regard to it. A perfectly satisfactory explanation has not been given nor has its psycho-pathologic significance been fully appreciated, possibly because of the difficulties of investigation necessarily involved. Dr. Pilgrim's article is a suggestive one, and indicative of the probable value of more general statistical studies of the kind in regard to insanity.

---

[1] Am. Jour. of Insanity, July.

Medical News.

ALABAMA.

The Birmingham Medical College began its seventh annual session, October 2.

Dr. Milton B. Kirkpatrick, Montgomery, has been elected county physician of Montgomery county to fill the unexpired term of J. H. Naftel, deceased.

St. Vincent's Hospital, Birmingham, will not be ready for opening for about two weeks, but a few patients are being received to relieve the strain on the temporary hospital.

CALIFORNIA.

Dr. T. Edward Bailey, San Francisco, has succeeded Dr. Walter S. Thorne as chief physician and gynecologist at St. Mary's Hospital.

Dr. Isadore E. Cohn, Berkeley, as a result of a competitive examination, has been appointed third assistant physician of the Napa State Hospital for the Insane.

The Alameda Board of Health is framing an ordinance for presentation and passage which will make it a misdemeanor for any undertaker to handle a dead body without first securing the physician's certificate.

Col. A. C. Girard, chief surgeon at the Presidio Hospital, has declined the position of chief surgeon, Department of the Lakes at Chicago, on the ground that the duties of his position in Chicago would be mostly office details, while in his present position he has great opportunities for surgical work.

One of two helminthologists who crawled into Los Angeles from Mexico some months ago, was fined last week $50 for practicing medicine in Long Beach without a license. He had already paid two $100 fines to the city for the same offense. He was let off easy this time on the promise of leaving the country.

COLORADO.

The new building of the County Hospital at Colorado Springs is completed at a cost of $25,000.

Dr. Frederick E. Warren and Miss Ida M. Miller, both of Denver, were married at the country home of the bride's parents, October 3.

The St. Luke's Hospital Aid Society, Denver, reports that during the year, 1010 patients were treated in the hospital and that eleven nurses were graduated from its training school.

Denver's mortality for September was 58, a death-rate of 13.13 per thousand per annum. The births for the month numbered 114. Twenty-one cases of smallpox, 17 of scarlet fever and 40 of typhoid fever were reported during the month.

DISTRICT OF COLUMBIA.

The Providence Hospital medical board, on October 2, elected Dr. Middleton F. Cuthbert, gynecologist and Dr. Joseph S. Wall a member of the medical staff.

The health officer of the District reports 108 deaths for the week ended October 4, a death-rate of 20.16 per thousand per annum. During the week 15 cases of diphtheria and 6 of scarlet fever were reported.

The intendant of the Government Hospital for the Insane has transmitted to the commissioners a report for the fiscal year ending June 30, together with estimates for maintenance and improvements for the following year. The total estimate for the above amounts to $210,600, and $22,753 for salaries and operating expenses. The value of farm produce raised during the year was $6376.98.

Howard University Medical Department held its opening exercises at Freedmen's Hospital, October 1. Prof. Hodgkin, of the dental department, made the opening address.

The Georgetown University School of Medicine opened its fall term October 1. Dr. George L. Magruder, dean of the faculty, presided and announced the following changes in the faculty: Dr. John F. Moran, professor of obstetrics, vice Dr. Henry D. Fry, resigned; Dr. Isaac W. Blackburn, who has been ill for two years, resumes his duties as professor of pathology and morbid anatomy.

ILLINOIS.

Dr. Frank B. Fisher, Springfield, was married October 3 to Miss Carrie Furber at Carlinville.

Dr. William J. Chenoweth, the oldest practitioner in Decatur, has gone to California, where he will reside for the future.

The State Board of Health has decided to carry its case against Dr. W. Frank Cross, charged with unprofessional conduct in connection with medical colleges, to the Supreme Court.

Chicago.

Dr. James Nevins Hyde has returned from a trip to Norway.

Dr. George W. Webster has been appointed a member of the Illinois State Board of Health, to succeed Dr. R. F. Bennett.

Dr. Sarah Hackett-Stevenson has returned from her trip to Europe, which included the congress in Paris and the Passion Play at Ober-Ammergau.

The regular quarterly medical examination closed October 11. Forty-one persons took the examination, twenty-seven of whom are candidates for physicians' certificates, eight for certificates of midwife, and six are classed under the head of "other practitioners."

Dr. Arthur R. Reynolds, secretary to the Galveston Relief Committee, returned from his tour of investigation in Texas, October 15. He thinks that the contributions from Chicago public schools should be applied to the replacement of the public school system in Galveston.

A number of Chicago "Doctors" who have bought diplomas from the Metropolitan Medical College, or have in other ways violated the laws governing the practice of medicine, have been arraigned by the State Board of Health, which is now making a vigorous war against illicit practitioners.

More than 130 medical societies thus far have appointed representatives to attend the Fenger banquet. Dr. Charles A. L. Reed, Cincinnati, will be toastmaster; and Drs. Joseph M. Mathews, Louisville; Charles A. Wheaton, St. Paul; Charles B. Nancrede, Ann Arbor; Nicholas Senn and others will be among the speakers.

Errors in the form of the instructions given the jury in the Superior Court have brought a retrial of the X-ray suit, in which Frank V. Balling, the plaintiff, was awarded judgment. The suit was the result of the application of the rays to Balling's ankles by Dr. O. L. Schmidt and W. C. Fuchs, Mr. Balling declared that in consequence he was compelled to submit to three painful amputations.

HEALTH DEPARTMENT.

The recorded deaths for the week ended October 13 numbered 449—an increase of 51 over the previous week and of 30 over the corresponding week of 1899. This increase is not so serious as was apprehended in the Bulletin of October 6, as a result of the sudden change of temperature at the close of that week. In fact, the increase is in deaths from diseases with which—except as to diphtheria—the weather has little to do. Cancer, consumption, and heart and nervous diseases account for 40 of the increase. The diphtheria mortality has as usual increased steadily since the opening of the schools on September 10. Up to that date the weekly average of deaths from diphtheria had been 8. Following are the deaths by weeks since school opening: September 15, seven; September 22, 9; September 29, 14; October 6, 15; October 13, 21—a weekly average of 15 for the last four weeks, or an increase of nearly 90 per cent. over the previous weekly average. The death-rate per thousand per annum was 13.77; for the corresponding week in 1899, it was 13.59, and for the week ended October 6, 1900, 12.20. Of males 250, and of females 199 died. Under one year 93 died; between 1 and 5 years 54, and over 60 years, 80. The principal causes of death were: Acute intestinal diseases, 50; heart diseases, 49; consumption, 46; nervous diseases, 32; pneumonia, 27; cancer and diphtheria, each 21; Bright's disease, 18; typhoid fever, 11; scarlet fever, 4; suicide, 9 and violence, 19. During the week 575 births were reported. In the laboratory, 77 bacteriological examinations were made and 81 samples of milk were analyzed, 6.17 per cent. of which were found to be below grade.

LOUISIANA.

The New Orleans Board of Health has neglected to attach the necessary 50-cent. war stamp to the marriage bonds issued since July, 1898.

Dr. T. Edward Schumpert, manager of the Shreveport Sanatorium, has associated with him in its management Drs. Thomas G. Ford and J. Ashton Blanchard.

The election of officers of the Charity Hospital board at Shreveport, October 9, resulted in favor of Dr. Robert A.. Gray, president; Dr. Randell Hunt, chief surgeon, and Dr. Isaac M. Callaway, resident physician and superintendent.

The State Board of Health has issued blanks to the various health officers and coroners throughout the state in accordance with the law passed by the last legislature regarding the collection of vital statistics in the country parishes. The reports are to be made quarterly, and from them the vital statistics of the state will be tabulated.

MARYLAND.

At the monthly meeting of the board of directors of Springfield Asylum for the Insane, October 10, it was decided not to admit feeble-minded and idiotic children to the institution.

Dr. Howard Bratton, health officer of Cecil county, reports that there were 26 cases of typhoid fever in that county in September, with 5 cases of diphtheria at Providence and 2 at Pleasant Hill.

Baltimore.

Dr. Charles O'Donovan was elected vice-president of the Catholic Club.

Dr. George W. Dobbin was married to Miss Beatrice Dunderale, of Chicago, October 14.

Dr. John C. Hemmeter has returned after a tour embracing the principal cities of Europe.

The College of Physicians and Surgeons formally opened for its twenty-ninth annual session on October 1.

In computing the death-rate after January 1, 1901, the health department will accept the U. S. census population figure.

Johns Hopkins University Medical Department opened October 1, with a total enrollment of 215. Dr. Percy M. Dawson has been made associate professor of physiology and Dr. William G. MacCallum associate professor of pathology.

The jail board has named a resolution requesting Dr. Thomas Opie, one of its members to consult with Dr. George L. Wilkins, jail physician, as the best way of keeping tuberculous prisoners isolated from other prisoners, and of otherwise lessening the possibility of a spread of the disease.

For the week ended October 13, the deaths were only 169 against 192 for the previous week, a death-rate of 16.24 per thousand per annum. There were 9 deaths from typhoid fever, 5 from diphtheria and "croup," 16 from tuberculosis, 8 from cancer, 7 from pneumonia, 10 from cholera infantum, and 12 from Bright's disease. New cases were reported of diphtheria, 49; typhoid fever, 47; scarlet fever, 10; measles, 14. Only 114 births were reported.

MICHIGAN.

An instance of cheese poisoning occurred at Climax, in which cheese there was found, at the State Laboratory of Hygiene, a virulent form of the colon bacillus.

The Delta County Hospital has completed a $4000 addition, and within two weeks, twelve additional rooms will be ready, which will give the hospital a capacity of 75 beds.

About two months ago H. Reynolds arrived in Coldwater from Detroit and began the practice of medicine. He was arrested October 10 on the charge of practicing without a license, and in the default of bail was locked up in the county jail.

A number of the diplomates of the Independent Medical College, Chicago, who thus far defied the law, appeared before the State Board of Examination and Registration, October 9 and 10 at Lansing. They are evidently beginning to appreciate that they must obey the law or leave the state.

Two buildings, each 50x104 feet and two stories high, are almost completed for the Upper Peninsula Hospital for the Insane at Newberry. The State Board of Corrections and Charities will recommend an appropriation of $171,000 to erect two more cottages, an infirmary and an amusement hall for the hospital.

The State Board of Health has received the following communication from a resident of one of the interior cities: "How does the State Board view the matter of death certificates? . . . We have two men here who have not been registered, and who have made application and been informed that they were not eligible, and yet they are doing business just the same as though they were. One of them has more funerals than all the other doctors put together."

MINNESOTA.

The establishment of a down-town corps of nurses for the poor, is under consideration in Minneapolis.

Dr. Nellie S. Shulean, Minneapolis, a graduate of Hamline University, has gone to Porto Rico as a medical missionary.

Forty-three applicants for licenses to practice medicine in Minnesota appeared before the State Board of Medical Examiners at St. Paul, Oct. 2. Four of the applicants were women.

The State Institutions for dependents have 306 more inmates than in September 1899, 142 of whom are in the state hospitals for the insane. There are now 6107 inmates in state institutions.

Additions to the teaching force in the medical department of Hamline University are the following: Dr. Horatio B. Sweetser, Minneapolis, professor of surgery; Dr. Frederick J. Plondke, St. Paul, instructor in histology; Dr. Charles F. Disen, Minneapolis, assistant in anatomy, and Drs. Lyle C. Bacon, Knox Bacon and Mason Allen, St. Paul, assistants in clinical medicine.

MISSOURI.

Dr. Edward Evans Parrish and Miss Estella Martha Mudd, both of Memphis, were married Oct. 2.

Dr. John Albert James James, St. Louis, was married to Miss Nelle Blanche Robeson, at Rochester, N. Y., Oct. 2.

Dr. W. Elmer Montgomery, Kansas City, was married to Miss Grace Hubbert, of Neosho, Mo., at St. Louis, Oct. 3.

Dr. William Baron, who has been studying in Germany for a year past, has returned to his home in St. Louis.

The Health Department of Kansas City has wisely decided to leave the problem of fighting smallpox and taking precautionary measures against it to the judgment of the city physician, Dr. Coffin.

Dr. S. C. James, the Kansas City member of the State Board, is making a praiseworthy effort to stop the illegal practice of medicine in his city. He is particularly after one whose diploma "by the Missouri Eclectic Medical College of Kansas City, Mo., was entirely complimentary and was not intended to indicate his attendance or graduation from this institution."

The crusade against unlicensed physicians in St. Louis has begun. The secretary of the State Board of Health has obtained warrants charging practice of medicine without a license, against three of the thirty-three unlicensed practitioners, and says that the day of arraignment for the others is just dawning.

NEW YORK.

Dr. James A. Cronin, Buffalo, was married to Miss Mame Richards, at Seneca Falls, Oct. 3.

In Utica during September, 102 deaths were reported, a death-rate per thousand per annum of 21.5. The birth-rate for the same period was 19.1.

An Armenian who claimed to be a licensed practitioner was sent to jail for 55 days by Recorder Morschauser, Poughkeepsie, for defrauding a boarding-house keeper.

The first of a series of small colonies or farms for consumptives has just been established at Schroon Lake, in the foothills of the Adirondacks, by the Indigent Consumptives' Association, of which Dr. J. Austin Kelly is president. A plot of ground nearly 5000 acres in extent has been purchased, which will be laid out in small farms, each having its own house, truck patch or vineyard, where the patients can work and have some diversion from the contemplation of their own and their neighbors' ills.

New York City.

Dr. Thomas M. Neafrey, house surgeon at the Harlem Hospital, was married a year ago to Miss Winters, of Sea Cliff, Long Island. As the rules of the hospital required all internes to be unmarried, he did not disclose his marriage until the expiration of his term on Oct. 1.

The City Branch of the Loomis Sanitarium for Consumptives has recently been enlarged, and the required number of beds added to make this hospital eligible for admission to the Hospital Saturday and Sunday Association. It has now been admitted to this association, being the thirty-ninth on the list.

Last week the health officer of the port discovered the first case of yellow fever that has developed among saloon cabin passengers this year. The patient was on the Ward line steamer *Havana*, and as he presented suspicious symptoms on the arrival of that vessel, he was placed on Hoffman Island for observation. By the next day there was no longer any doubt that he was suffering from yellow fever.

At a meeting of the medical board of the Metropolitan Dispensary and Hospital, the following resolution was passed: "Inasmuch as by the death of Dr. John M. Brown [see The Journal, Sept. 29, p. 836], the Metropolitan Dispensary and Hospital has sustained a loss which is poignantly felt and with difficulty retrieved, and since, individually, we miss the rugged honesty, the incorruptible friendship which was constantly evidenced to us who knew him intimately, be it *Resolved*, that this feeble expression of our esteem for his character and our appreciation of our loss be spread on the minutes, and a copy of this resolution be sent to his family and to the medical press."

OHIO.

Dr. Philip Sebastian Rieg and Miss Frances Margaret Weick, both of Toledo, were married, October 10.

Dr. W. Merritt Johnston, Findlay, has been elected county physician of Hancock county, to succeed Dr. Harry D. Belt.

Dr. and Mrs. Yeatman Wardlow, Columbus, were robbed of nearly $3000 in cash and jewels at a hotel in New York, where they were spending their honeymoon.

McGuffy, Hardin county, is having an epidemic of smallpox. Dr. Charles O. Probst, secretary of the State Board of Health, has been notified that there have been 53 cases, but that the disease is now abating.

The medical department of Western Reserve University, Cleveland, began its fifty-sixth year on October 3. Dr. Henry S. Upson delivered the opening address. Dr. George W. Crete has been made professor of clinical surgery.

A physicians' social club is to be formed in Cincinnati, with headquarters in the old Union City Club. The founders are Drs. N. Pendleton Dandridge, William H. Taylor, Jr., Joseph Hall, Jr., John E. Griewe, Paul Gillespie, Mark A. Brown and Charles E. Caldwell. The club will be known as the Cincinnati Medical Club.

The health officer of Cincinnati says that his department has sent to the hospital more than a dozen prostitutes suffering from contagious diseases, all of whom had medical certificates pronouncing them free from venereal disease. The inspection of these women by the health department is opposed by some physicians of the city.

The State Board of Medical Examination and Registration expects many of the osteopaths to leave the state within the next few weeks. None of them presented themselves at the last examination and the board will take steps to have those remaining in the state indicted for violation of the provisions of the law. The next examination will be held in Columbus, for three days during the week commencing Dec. 1.

That local boards of health may step in and take charge of cases of illness where the patient is not receiving proper attention, is the substance of a decision rendered by Dr. C. O. Probst, of the State Board of Health. Dr. H. A. Snorf, of Ansonia, asked for instructions regarding a little girl lying very ill, whose parents were Dowieites and refused to call in a physician. After consultation with the attorney-general, Dr. Probst replied that there was no doubt that the local board of health could take entire charge of the case, send a physician to take care of the child, and if necessary remove her to a hospital for proper treatment.

PENNSYLVANIA.

Dr. John B. Lowman, Johnstown, returned on Oct. 5, from his trip to Europe.

The West Penn Medical College, Pittsburg, opened for its annual session on Oct. 2.

Dr. David T. McKinney, New Brighton, was married to Miss Catherine Minnis, at New Haven, Oct. 3.

The Lock Haven Hospital has received a donation of a building site more than four acres in extent, on Susquehanna avenue, from Mr. Wilson Kistler, president of the hospital association.

The State Convention of County Commissioners, which met at Allentown October 9, considered whether or not the office of coroner should be abolished. Opinion seemed to be divided. One resolution provided for the repeal of the law which requires registration of the births and deaths of persons in the state.

The State Directors of the Poor made an investigation of the insane asylum of Luzerne county, October 11, and found the management to be so good that they have decided to recommend the plan of this institution to others in the state. The new building cost $300,000. The inmates of the asylums at Danville and Wernersville have been taken to this hospital.

Philadelphia.

Drs, Judson Daland, W. M. L. Coplin and Charles P. Noble have returned from their trip to Europe.

Dr. F. Savary Pearce has been appointed clinical professor of nervous diseases in the Medico-Chirurgical College, to succeed Dr. Charles W. Burr, resigned.

Dr. Joseph McFarland, professor of pathology, delivered the address at the opening of the Medico-Chirurgical College, on "The Relation of the Mosquito to Malaria Fever."

Dr. Ella B. Everett delivered the address to the students at the opening of the Woman's Medical College, September 26. The following changes in faculty are announced: Dr. William V. Laws, professor of clinical and operative surgery, and Mae T. Harders, demonstrator of pharmacy.

Edward M. Paxson, formerly chief justice of the Supreme Court of Pennsylvania, has been elected president of the Medico-Chirurgical College, to succeed C. William Bergner, resigned. It has been decided to select only laymen as members of the board of trustees of this college, hereafter. At the present time a large number of physicians serve on the board.

The seventeenth annual report of the Kensington Hospital for Women has been issued and shows that there were treated in the hospital during the year 839 cases, as compared with 602 cases in the previous year. Several additions are to be made at an early date, including an isolated ward for septic cases. Dr. Charles P. Noble was elected surgeon-in-chief for the ensuing year. The new directors are Bishop O. W. Whitaker, William P. Ellison, Dr. Howard A. Kelly and John B. Stetson.

The deaths in the city for the week ended October 13 were 338, an increase of 4 over the previous week, and a decrease of 44 as compared with the previous week of 1899. The principal causes of death were: Apoplexy, 3; nephritis, 22; cancer, 16; tuberculosis, 55; heart disease, 22; bronchitis, 4; pneumonia, 14; inflammation of stomach and bowels, 14; marasmus, 17; poisoning, 2; suicide, 2; and tetanus, 1. Of contagious diseases 99 cases of diphtheria were reported, with 16 deaths; scarlet fever, 24 cases, 1 death; typhoid fever, 49 cases, 10 deaths.

The University of Pennsylvania will be the recipient of a gift on the part of Mrs. S. Weir Mitchell, who intends building as a memorial to her daughter an addition to the hospital, which will be used as a general ward or will be devoted to the treatment of contagious diseases. The idea of a pay hospital for contagious diseases originated in Philadelphia several years ago, and up to this time about $5000 or $6000 has been raised to establish that institution, The new building will be a welcome addition to the University.

At the last meeting of the Board of Charities and Corrections, held a few days ago, Dr. John V. Shoemaker introduced a resolution to enlarge the clinical teaching in the Philadelphia Hospital. In this way it is hoped to offer advantages similar to those found in Vienna, and other cities of Europe. The general clinics and pathologic instruction are to be free to all students registered at the different medical schools. General clinics are to be given in the amphitheater twice each week, and assignments for clinical lectures are to be made from the medical staff. Classes of students are not to exceed ten at one time. Surgical and gynecological cases are to be open to physicians and students under proper regulations. Clinical lectures on and presentation of cases of insanity will be made a special feature, and the teaching of the different specialties will be arranged by the respective members of the medical staff. Pathologists will be allowed to have classes, not exceeding twenty-five in number in the hospital museum. While such a liberal offer has been made for the utility of the different clinics to be held, the welfare of the sick is to be considered the first duty of the physician. Dr. Simon Flexner and Dr. Joseph McFarland were appointed pathologists to the hospital, and Dr. R. F. Sonnekamp assistant physician to the insane department. Dr. Robley D. Newton becomes surgical registrar.

TENNESSEE.

Dr. Heber Jones, President of the Memphis Board of Health, has gone to Europe for a three months' vacation.

The Vanderbilt University Medical Department, Nashville, opened for the college year, Oct. 1. Dr. Richard Douglas delivered the address of welcome and Dr. John A. Witherspoon conducted the first clinic at the City Hospital.

Dr. Henry P. Coile, city physician of Knoxville during 1898 and 1899, who sued the city for $5,000 which he claimed was due him for attending smallpox cases while in the employ of the city, has been non-suited and will appeal to the Supreme Court.

Initial steps were taken at the recent meeting of the Tri-State Medical Society of Tennessee, Alabama and Georgia, at Chattanooga, to secure medical legislation in the three states mentioned regulating or prohibiting the marriage of habitual criminals, persons afflicted with incurable diseases, drunkards and victims of harmful drugs.

The Medical College of the University of Nashville opened for its annual session, Oct. 1. Dr. William G. Ewing made the annual address, which dealt with the history of the institution. The changes in the faculty are: Dr. Carl C. Warden, professor of anatomy; Dr. William G. Frierson, adjunct professor of surgery, and Dr. J. Dillard Jacobs, professor of physiology and hygiene.

Two undertakers, named Thompson, were recently convicted in Memphis of having engaged in cadaver traffic. They were said to have shipped bodies out of the state in zinc-lined and air-tight trunks. The undertakers were sentenced to pay a fine of $750 each, and to serve 11 months and 29 days in the workhouse. The case was appealed to the Supreme Court, where the finding of the lower court was approved. Governor McMillan was then petitioned for a pardon, and wrote to the clerk of the Shelby County Criminal Court instructing him not to execute the sentence until the governor could look into the case. Some three months later, as the governor had taken no action in the matter, the sheriff was instructed by the judge of the criminal court to carry the sentence into execution.

TEXAS.

The Health Department of Galveston has established two depots for free distribution of disinfectants.

The John Sealy Hospital, Galveston, is being repaired at the expense of the son and daughter of the philanthropist who donated the building to the state.

The Galveston Board of Health has issued regulations requiring innkeepers to report any case of sickness to the health physician within six hours; and also requiring physicians to report to the same official within six hours full particulars of any patient "sick of any malignant fever or infectious or pestilential disease."

Brackenridge Hall, the dormitory for the female students of the medical department of the University of Texas, Galveston, which was badly wrecked, is being completely restored and refurnished by Col. George W. Brackenridge, of San Antonio. He has also advanced to the university the money needed for the repairs to the medical school.

VIRGINIA.

The will of the late Dr. Benjamin Harrison, Richmond, was admitted to probate Sept. 21. The value of the estate is $2000.

Dr. Charles V. Carrington, Richmond, has been appointed surgeon to the State Penitentiary, to succeed Dr. Benjamin Harrison, deceased.

The University College of Medicine, Richmond. held its formal opening Oct. 5. Dr. Landon B. Edwards presided. The address was delivered by Dr. Henry Pervis Smith, Davidson College, N. C., on "The Intellectual Value of Scientific Training."

The Medical College of Virginia, Richmond. began its sixty-third annual session October 20. Dr. Christopher Tompkins. dean of the college, delivered the inaugural address. Dr. Ennion G. Williams has been made professor of histology, pathology and bacteriology, vice Dr. Ernest C. Levy. resigned.

WASHINGTON.

Dr. Samuel J. Holmes, bacteriologist of the board of health of Seattle, has resigned, after a service of two years.

Dr. William G. Booth, Seattle, was married to Miss Fannie Hamilton Norfolk, of North Walbrook, Md., September 11.

St. Luke's Hospital, Spokane, was reincorporated September 7. A site for the new building has been donated by John A. Finch.

The corner-stone of the Sisters of Peace Hospital, New Whatcom, was laid with appropriate ceremonies by Bishop John O'Dea, on September 23.

WEST VIRGINIA.

The incorporation of the Harrison County Hospital Company at Clarksburg is announced.

Morgantown has a new hospital, which was opened for service, October 3. It has been thoroughly equipped by its owner, Dr. Spencer S. Wade, and is intended for the use of the local profession.

Dr. Cassius C. Hogg. Huntington, has been promoted and is now major and surgeon, assigned to the Second Infantry, W. Va. N. G.; and Dr. G. Clarence Schoolfield, Charleston, has been commissioned first lieutenant and assistant-surgeon and assigned to the same command.

WISCONSIN.

Racine has about 50 cases of typhoid fever. Some of the physicians have been lax in reporting cases.

Dr. Robert A. Kitto, Racine, who lost an eye by a street-car accident, a year ago, has so far recovered $18,000 from insurance companies.

The Milwaukee Medical College opened for its seventh annual session. October 2. Dr. John Madden delivered the address of welcome.

At a meeting of the State Board of Medical Examiners held at Oshkosh. October 9 and 10. 75 licenses were granted to applicants with diplomas from reputable colleges. Four applicants with diplomas from the Metropolitan College of Illinois were denied licenses.

CANADA.

Dr. A. Holmes Simpson, Winnipeg, has been appointed by the Provincial Government of Manitoba, chairman of the Provincial Board of Health.

Dr. Werster, of the Rockwood Asylum, Kingston, has been transferred to the Hamilton Asylum for the Insane, and Dr. Herriman of the Hamilton Asylum goes to the Rockwood Asylum. Both changes are promotions and will come into effect November 1.

News from Dawson under date October 4, states that quarantine has been established at the Forks of Bonanzo and Eldorado, against smallpox. Smallpox is epidemic at Eldorado, twelve miles from Dawson. There are also twelve cases on the isolation island, two miles below Dawson. A smallpox hospital is under construction at Dawson, and there is felt some uneasiness lest that city be quarantined against the outside world.

The Medico-Chirurgical Society of Montreal has elected the following officers for the ensuing year: Dr. J. Perrigo, president; Dr. Stirling, first vice-president; Dr. Macarthy, second vice-president; Dr. Bazin, secretary; Dr. Jack, treasurer; and librarian, Dr. Lockhart. The retiring president, Dr. J. George Adami, in his report, stated that the society was ready to go on with the work of compiling the addendum to the British Pharmacopeia, and that it would co-operate with Westmount in the erection of a contagious disease hospital.

QUEEN'S UNIVERSITY, KINGSTON.

A public meeting was held in the city of Kingston, October 9, for the purpose of discussing the granting by the city of $50,000 to Queen's University. Principal Grant said that the passing of the bonus would in the first place anchor Queen's to Kingston and put an end to rumors about the University going elsewhere; then it would increase the capacity of the students from 500 to 1000. It would also give Kingston a right to go to the provincial government, showing that there are only two educational centers in Ontario, and that Kingston has as much right for consideration as the other one in Toronto. This attitude of Queen's is interesting to medical educationists throughout the province, as if aid be granted by the government as sought, it would be placing the Medical Department of Queen's on a par with the Medical Department of Toronto University.

FOREIGN.

The French medical papers are urging the imposition of an extra tax on alcohol and absinthe for the purpose of raising funds for tuberculosis sanatoria.

Dr. Silva, a delegate from Mexico to the International Medical Congress. stated in his address that no case of criminal abortion had ever come before a Mexican court.

Dr. A. Kuhn. professor of otology at Strassburg, died Sept. 16, 63 years of age. His principal contributions to scientific literature were on the anatomy of the ear.

The present mayor of Lyons, France, is Dr. Augageur, who is at the same time professor in the medical faculty and surgeon-in-chief at one of the hospitals. His predecessor in the office of mayor was also a physician. and occupied the position for thirty years.

A life-insurance company in Gotha states that the number of policy-holders who have died of cancer during the last ten years is 1 per thousand more than during the preceding decade. The greatest increase is in policy-holders between the ages of 66 and 70.

The University of Odessa has organized a medical department and placed it in charge of Podwyssotzki, the eminent pathologist of Kieff. Both the Russian and German medical schools report a diminished attendance this year. In Germany the number of medical students has fallen from 8848 in 1890, to 7518 this year, while the attendance in the law schools has increased by 3000 during this period.

The medical inspectors of schools in Frankfurt, Germany, receive $250 a year, and have oversight over 1700 scholars. Two hours every two weeks must be devoted to each school. The children are given a "health book" when they first enter, and it accompanies them through all their school life. Several of the large cities of Germany now have medical inspection of schools. but the system has not yet been introduced into Berlin.

The editors of the *Bibliographia Medica* announce that they will soon commence the publication of special editions of the *Bibliographia* each limited to one of the following specialties: 1, anatomy. physiology and veterinary subjects; 2, hygiene, legal medicine and assistance; 3, therapeutics and materia medica; 4, internal and general medicine; 5, general and special surgery. and 6, gynecology, obstetrics and pediatrics.

The Berlin sickness-insurance institution (Anstalt) has doubled the capacity of its sanatoria during this last year.

By judicious selection of the inmates 85 per cent. of the 592 patients dismissed in 1899 from the sanatorium at Goetersgolz have been able to resume their occupation. The institution is to extend the principle of sanatorium treatment to syphilitic policy-holders after this year, and has already acquired land for the purpose in one of the suburbs of Berlin.

The Slavonic members of the profession have taken measures for closer organization and more extended intercourse between them and the outside world. A committee has been formed to decide on a uniform scientific terminology from comparative study of Russian, Polish, Bohemian, Servian, Bulgarian, etc. Dr. Pesina, of Prague, is the secretary. Subcommittees are to be formed in each of the countries interested. It has also been decided to publish a general review of contemporaneous Slavonic medical literature, entirely in French. Dr. Gundrum is in charge of this matter.

LONDON LETTER.

THE PLAGUE IN GLASGOW.

Thanks to the very careful and elaborate precautions of the authorities, of which I have informed you, the outbreak of plague appears to have come to an end. For nearly a fortnight no new cases have occurred. At present there are in hospital 21 cases of plague and 2 suspected cases. Two deaths have taken place in the past week. The number of persons who have been in contact with cases of plague and are detained under observation in reception houses is now reduced to 19. No doubt now remains that the Glasgow outbreak is of the same nature as that which ravaged London two and a half centuries ago; the symptoms are the same. But the means of recognition, especially the bacteriological, and the methods of sanitary defense are quite new; hence the different result. Glasgow has reaped the reward of having in the first place keen medical men who quickly recognized, first, that they had an infectious disease of doubtful nature under observation, and soon afterward that it was the dreaded plague, and in the second place of an elaborate sanitary system worked by an alert police. The most satisfactory theory of the origin of the outbreak is that the source was an unrecognized ambulant case which occurred in some sailor or traveler. As in other diseases, while plague is extremely easy of recognition in well-marked typical cases it is not so in its slighter and atypical forms. This fact is borne out in the present outbreak, for many of the cases would never have been recognized but for the association of the patients with well-marked cases. Yersin's serum was used in the treatment and seems to have given very satisfactory results. It was injected into the veins in doses of 20 c.c. Persons who were known to have been in contact with cases were given subcutaneous injections of 10 c.c. as prophylaxis.

THE SOUTH AFRICAN HOSPITAL COMMISSION.

The commission has left Johannesburg and visited the hospitals throughout Natal, taking evidence as it traveled. Further evidence was given that the medical staff was undermanned and hampered with "red tape." At Pietermaritzburg it was stated that the hospital was unsuitable. It was infected with bugs, which were found even under the patient's splints. Some men suffered terribly, and one enteric patient ran away in delirium, saying he could not stand the bugs. At Kimberley the evidence given by the doctors and the members of the hospital staffs conflicted with that given by the soldiers. The former agreed that the hospitals in the town were well arranged and well equipped, and that no complaints had been made. The latter, on the contrary, complained of bad treatment at Paardeburg owing to lack of administrative ability. The field hospitals, they said, were so badly placed that many men had to lie in pools of water. The camp at Maitland was placed in a similar position, the men lying in tents full of water, many of them without blankets, overcoats or oilskins.

The letters published by Mr. Burdett-Coutts in the *Times*, which it will be remembered were the cause of the commission, have made him immensely unpopular with a section of his own Tory party. His leader, Mr. Balfour, treated him with gross discourtesy in the House, and ridiculed even his cogent arguments. He has been opposed at the general election, which is now proceeding, by another Tory candidate. However his constituency, Westminster, have marked their approval of his actions by returning Mr. Burdett-Coutts by a majority of 2715 votes against 439.

THE CONSUMPTION OF TOBACCO IN THE UNITED KINGDOM.

According to the government report the consumption of tobacco was higher in 1899-1900 than it has ever been known before, with the exception of a single year. It was 90,000,000 pounds, which is 2 pounds per head of the population. On the point of purity the report is very satisfactory. In 95 samples taken from manufacturers and dealers 20 were found to be mixed with licorice or glycerin. Twenty-two specimens of snuff were analyzed and except one, which contained an illegal proportion of alkaline salts, all were conformable to law.

MALARIA AND MOSQUITOES.

The part played by mosquitoes in the transmission of malaria is now being very actively investigated. The recent exceedingly dramatic attempt to prove Dr. Manson's theory has been so far successful. Drs. Sambon and Lowe, of the London School of Tropical Medicine, have now lived in a mosquito-proof tent, in the fever-stricken Roman Campagna from the early part of July up till September 21, without contracting malaria. What may be called a complimentary proof of the mosquito theory is equally satisfactory. Mr. P. T. Manson, son of Dr. Manson, has allowed himself to be made the subject of experiment—to be bitten by mosquitoes sent from Rome to London, which had been fed on a patient with a double benign quartan infection. Mr. Manson was bitten on August 29 and 31 and on September 2, 4, 10 and 12. On September 13 he had a feeling of languor and felt chilly, which symptoms were followed by headache, pains in the bones and a temperature of 101.4. The usual symptoms of tertian fever developed and the spleen became enlarged. Tertian parasites were found in his blood. Under quinin he recovered.

At the end of 1898 a committee was appointed jointly by Mr. Chamberlain and the Royal Society to investigate malaria, and it was determined, in view of the connection with mosquitoes, that collections should be made of the different species in the various tropical colonies. These have been forwarded to the Natural History Museum at South Kensington. Over 3000 specimens have been received and more are constantly coming in. The work of identifying and classifying them is performed by a professional dipterist, Mr. Theobald, who is preparing a monograph on mosquitoes, based on the collections at the museum. The genus Anopheles, which is the medium by which malaria is transmitted from person to person, is represented in the museum by 22 species. Although the genus is world-wide, the distribution as regards species is not wide. One of the greatest distances between any two localities for the same species is Formosa and the Straits Settlement.

Correspondence.

Yellow Fever Etiology.

Washington, D. C., Oct. 8, 1900.

To the Editor:—In Surgeon Wasdin's paper, published in The Journal, Oct. 6, 1900, p. 807, he says:

> During my experimental work we were honored by a visit, at our laboratory in Havana, from Dr. Sternberg, who said to me, while passing through our animal room, that the strongest argument against the acceptance of the specificity of any one of the organisms advanced as the cause of yellow fever, was the fact that no one of them, during experiments in laboratory, had ever communicated this disease by natural infection to the animals of those laboratories; and he asserted that, whenever such infections should occur, the lesions being characteristic, and the organism recovered, he would accept that organism thus demonstrated as the cause of yellow fever, and such demonstration as the proof of its specificity.

I think that Dr. Wasdin must have misunderstood me. My recollection is that I said to him, what I have frequently said to others, that to my mind one of the strongest arguments against the specific rôle of Sanarelli's bacillus was the fact that no one—man— had contracted yellow fever from exposure in laboratories where experiments upon animals were being conducted. Man is known to be especially susceptible to yellow fever, whereas there is, so far as I know, no satisfactory evidence that any of the lower animals suffer from the disease during the prevalence of an epidemic. During my first visit to Havana, in 1879, I exposed various animals, including dogs, guinea-pigs and rabbits, on a filthy ship in the harbor, which I assumed to be infected, as nearly all the members of the crew were sick on board with yellow fever. After this exposure I carefully observed my animals for several days, taking their temperature twice daily, but the result of the experiment was entirely negative.

In a report by Reed and Carroll, of their investigations made at the Army Medical Museum in this city, not yet published, but soon to appear in the *Journal for Experimental Medicine*, they arrive at the following conclusions: "1. Bacillus X (Sternberg) belongs to the colon group. 2. Bacillus icteroides (Sanarelli) is a member of the hog-cholera group. 3. The various channels of infection, the duration of the disease and the gross and microscopical lesions in mice, guinea-pigs and rabbits are the same for the bacillus icteroides and the hog-cholera bacillus. 3. The clinical symptoms and the lesions seen in dogs inoculated intravenously with bacillus icteroides are reproduced in these animals by infection with the hog-cholera bacillus. 5. Bacillus icteroides when fed to the domestic pig causes fatal infection accompanied by diphtheritic, necrotic and ulcerative lesions in the digestive tract, such as are seen in hogs when infected with the hog-cholera bacillus. 6. This disease may be acquired by exposing swine in pens already infected with bacillus icteroides, or by feeding them with the viscera of infected pigs. 7. Guinea-pigs may be immunized with sterilized cultures of bacillus icteroides against a fatal dose of the hog-cholera bacillus, and vice versa. 8. Rabbits may be rendered immune by gradually increasing doses of a living culture of bacillus icteroides of weak virulence against a fatal dose of a virulent culture of the hog-cholera bacillus. 9. The sera of animals immunized with bacillus icteroides and the hog-cholera bacillus show a marked reciprocal agglutinative reaction. 10. While the blood of yellow fever practically does not exercise an agglutinative reaction upon bacillus icteroides, the blood of hog-cholera agglutinates this bacillus in a more marked degree, thus pointing, we think, to the closer etiological relationship of this bacillus to hog-cholera than to yellow fever."

It is well known that mice, rabbits and guinea-pigs are very susceptible to infection by the hog-cholera bacillus and that they may be readily infected through the respiratory tract. It is difficult to understand how Drs. Reed and Carroll, and their laboratory assistants, who have been conducting experiments with Sanarelli's bacillus during the past two years, and during the summer months as well as in winter, could have escaped infection if this is truly the specific germ of yellow fever. The same remark applied to Dr. Wasdin and many other non-immunes who have conducted similar experiments in various parts of the world. These experiments at the laboratory of the Army Medical Museum included a large number of inoculation experiments upon lower animals and the making of autopsies when they died. That Dr. Carroll was susceptible to the disease is shown by the fact that he has suffered a severe attack this summer in Havana.

Of course, precautions as regards disinfection are taken, but it would appear that a lot of animals infected with the yellow-fever germ kept in the animal room of a laboratory during the summer months would be very likely to give rise to a local epidemic of the disease, or at least to infect a non-immune attendant whose duty it was to clean their cages.

From Wasdin's point of view the question of yellow-fever etiology is settled. I regret to say that I can not concur in this opinion. The researches which have been made by the board of which Reed and Carroll are members, in Havana during the present year, are not favorable to this view. I think, therefore, it will be wise for conservative physicians not to consider this matter as definitely settled until the evidence is all in. I may remark that the Liverpool School of Tropical Medicine has sent a commission of experts to study the disease in Brazil. I would also call attention to the fact that the researches of Dr. Adolph Lutz, a very competent bacteriologist, made at San Paulo, Brazil, are not favorable to the Sanarelli bacillus. His results are published in the *"Rivista d'Igiena e Sainta Publica* (July, 1900). Very truly yours,

George M. Sternberg.

Deaths and Obituaries.

Joseph Payson Wright, M.D., assistant surgeon-general U. S. A., died suddenly at his home in Washington, October 8, aged 74. He was the son of Brevet Brigadier-General J. J. B. Wright, surgeon, U. S. A., a distinguished officer of the medical department whom many will recall personally. He graduated in arts at Dickenson College, Carlisle, Pa., 1858, and in medicine, 1860. His record of service is one extending back to the early years of the civil war. He entered the service as assistant-surgeon in May, 1861; was promoted to a captaincy in May, 1866; to a majorship in July of the same year; as lieutenant-colonel in April, 1889, and attained his final rank, that of colonel and assistant surgeon-general, on May 16, 1894. During the civil war his service was principally in the departments of Ohio and Cumberland, with General Grant's army in the field at Florence, Miss., and on various executive duties as medical purveyor and assistant medical-director. His long service necessarily took him to various posts and stations, chiefly in the West. He was ordered to the military prison at Fort Leavonworth, Kan., in July, 1884, at which place he served many years. During his more recent service Colonel Wright served as medical purveyor in charge of the large depot in St. Louis, from December, 1893, until he was detailed as chief surgeon, headquarters, department of Dakota, St. Paul, Minn., November 24, 1899. At the time of his death he was on leave of absence pending his retirement on Dec. 25, 1900 .

William V. Morgan, M.D., a prominent surgeon of Indianapolis, at one time in charge of the department of surgery of the *Medical and Surgical Monitor*, died October 3 of peritonitis, aged 47. He was graduated from the medical department of Washington University in 1875. He had been a member of the faculty of the Central College of Physicians and Surgeons, was ex-president of Marion County Medical Society, and of the Mitchell District Medical Society, and member of the American Medical Association.

George W. Seay, Jr., M.D., Nashville, Tenn., a graduate of Vanderbilt University medical department in 1887, died September 26, from a gunshot wound in the head, aged 35. He was a member of the faculty of the University of Tennessee, major-surgeon of the 5th Tennessee Infantry, and served during the Spanish-American War as assistant-surgeon, 2d Tennessee Infantry, U. S. V.

Joseph McKee, M.D., who had resided in South Denver, Colo., for about twenty years, died September 27. He was graduated from the medical department of Western Reserve University, Cleveland, Ohio, in 1852.

N. Rounds Barnes, M.D., Binghamton, N. Y., a graduate of Albany Medical College in 1858, and in the Civil War surgeon of the 76th and then of the 184th Infantry, N. Y. V., died at his home September 30, aged 65.

Charles Roemelt, M.D., acting assistant-surgeon, U. S. A., died July 20, while serving in the Philippines. Dr. Roemelt was born in Elmira, N. Y., in 1876, and was graduated from the University of Buffalo.

Stephen E. De Witt Hoornbeck, M.D., College of Physicians and Surgeons, New York, 1865, died at Ellenville, N. Y., October 3. He had for some years abandoned medicine for general business.

William A. Grover, M.D., Berkshire Medical College, Pittsfield, Mass., 1843, died at Berkeley, Cal., October 4, aged 82 years. He was the first secretary of the California State Medical Society.

John Cortee Fairfax, M.D., University of Pennsylvania, 1853, died, after a brief illness, at his home, "Northampton," Prince George County, Maryland, October 28, aged 70 years.

John A. Leader, M.D., University of Vermont, 1888, a practitioner of Lewiston, Me., aged 35, died at Boston, October 9, after undergoing an operation for ear trouble.

Thomas J. Woolf, M.D., New Iberia, La., a graduate of Tulane University medical department, New Orleans, in 1878, died at Denver, Colo., September 30, aged 48.

Crawford Irwin, M.D., Jefferson Medical College, 1847, died at Hollidaysburg, Pa., October 8, aged 76 years. He was an ex-president of the State Medical Society.

Jacob P. Russel, M.D., Medico-Chirurgical College, Philadelphia, 1888, died October 8. at his home in Philadelphia, after a lingering illness, aged 64 years.

John P. Hodges, M.D., Danville, Ala., who was graduated from the University of Nashville medical department in 1873, died September 25, after a long illness.

Stephen D. Thach, M.D., Vanderbilt University medical department, Nashville, Tenn., 1891, was assassinated at his home, Decherd, Tenn., October 1.

Lawrence M. Gould, M.D., Harvard University, 1877, died suddenly at Portland, Me., while on a vacation. He was practicing at Hyde Park, Mass.

Samuel Pangburn, M.D., Ohio Medical College of Cincinnati, 1866, died at his home in Maysville, Ky., October 4, of apoplexy, aged 62 years.

Charles Y. Swan, M.D., College of Physicians and Surgeons, New York, 1856, died at Morristown, N. J., October 8, aged 65 years.

Thomas A. Atchison, M.D., one of the old and esteemed physicians and citizens of Nashville, Tenn., died October 2, aged 83.

Wellington Mason, M.D., University of Pennsylvania, 1898, died at Philadelphia, September 30, of appendicitis, aged 35 years.

Charles C. Crawl, M.D., Omaha Medical College, 1896, died at Randolph, Neb., October 7, of injuries received in a runaway.

William Webb Browning, M.D., Bellevue Hospital Medical College, 1884, died October 3 at Brooklyn, N. Y., aged 48 years.

Ralph J. Wenner, M.D., University of Wooster, 1892, died at his home in Cleveland, Ohio, October 9, of typhoid fever.

A. J. Welfley, M.D., Jefferson Medical College, 1896, died at Berlin, Pa., October 3, of pulmonary tuberculosis.

Junius N. Bragg, M.D., Tulane University, 1861, died at his home, Camden, Ark., October 2, aged 60 years.

Edward Richardson, M.D., Transylvania University, 1858, died October 9, at Louisville, Ky., aged 70 years.

Alfred T. Brosseau, M.D., University of Victoria College, 1867, died October 9, at Montreal, Que.

R. T. Mead, M.D., Albany Medical College, 1863, died at his home in Manistee, Mich., October 10.

Frank W. Crane, M.D., Buffalo University, 1868, died at Corfu, N. Y., aged 65.

Therapeutics.

TUBERCULOSIS.

TURPENTIN IN TUBERCULOSIS.

℞.	Terebinthinæ	ʒiv	16
	Cretæ preparatæ	ʒii	8
	Sacch. albi	ʒii	8
	Pulv. acaciæ	ʒii	8
	Aquæ cinnamomi, q. s. ad	℥iv	128

M. Ft. emulsio. Sig. Shake. One dessertspoonful three times a day on an empty stomach. —*Med. Record.*

TUBERCULOUS COUGH.

℞.	Syrupi pruni virginianæ		
	Tinct. lobeliæ		
	Tinct. sanguinariæ		
	Syrupi ipecacuanhæ, āā	ʒii	8
	Tinct. capsici	ʒi	4

M. Sig. One teaspoonful every two hours.

Med. Summary.

SURGICAL TUBERCULOSIS OF JOINTS.

℞.	Formalin	m. lxxv	5
	Glycerini, q. s. ad	℥iii	96

M. Sig. As an injection in tuberculous joints.

Hahn recommends the above as surpassing iodoform in such cases. He advises that the pus be evacuated by syringing, the cavity washed and one-third as much of the solution be injected as pus evacuated. It may be repeated in two weeks if necessary. —*Denver Med. Times.*

TREATMENT OF TUBERCULOSIS.

Knopf's outline of treatment in the "Twentieth Century Practice of Medicine" is as follows:

HYGIENIC TREATMENT.

a. Sanatorium treatment.

b. Home treatment, such as choosing for the patient the largest, pleasantest, sunniest, best-ventilated rooms. There should be no carpets, heavy curtains or superfluous furniture.

c. Aerotherapy and pneumotherapy.

d. Solar therapy. Exposure of the whole body in its nude state to the air and the rays of the sun is very favorable to metabolism and oxygenation and renders the cutaneous system less susceptible to the changes.

e. Attention to dress and personal hygiene.

f. Hydrotherapy.

g. Dietetic treatment.

h. Medicinal and symptomatic treatment.

SYSTEMIC TREATMENT.

Marfan prescribes cod-liver oil, phosphorus and creosote as follows:

℞.	Olei morrhuæ	℥xss	336
	Creosoti	℥ss	16
	Phosphori, 1/1000	℥i	32

M. Sig. One dessertspoonful after each meal.

This combination is very efficacious if well borne.

—*American Text-Book of Therapeutics.*

Hare says: 1. Never use cod-liver oil when the disease is past the primary stage unless fibrous changes are going on and the changes are slow. 2. The use of it during the rapid degenerative changes is harmful, as it is of no service, disorders digestion and destroys the appetite.

℞.	Creosoti carbonatis		
	Ammonii sulphoichthyolatis, āā	ʒiv	16
	Glycerini	℥i	32
	Aquæ menthæ piperitæ	ʒiiss	10

M. Sig. Ten to thirty drops three times a day.

—Goldmann.

Landouzy states that benefit is derived from saline injections subcutaneously by reason of reflex action on the nervous system. The formula he uses is as follows, given in small doses:

℞.	Sodii phosphatis	gr. lxxv	5
	Potassii phosphatis	gr. lxxv	5
	Sodii chloridi	gr. lx	4
	Sodii sulphatis	ʒv	20
	Aquæ destil	℥vi	192

M. Sig. To be used hypodermically in quantity desired.

℞.	Olei morrhuæ	℥vi	192
	Glycerini puri	℥i	32
	Tinct. quillajæ (soap-bark)	ʒiss	6
	Aquæ lauracerosi	ʒi	4

M. Ft. [illegible] one tablespoonful two or three times [illegible] —*Med. News*

℞.	Olei morrhuæ	℥xii	384	
	Syrupi tolutani	℥vi	192	
	Tinct. tolutani	gtt. xii		75
	Olei caryophylli	gtt. ii		12

M. Sig. Shake well and take a tablespoonful two or three times a day.

—Bricemoret: *Twentieth Century Practice of Medicine.*

℞.	Olei olivæ	℥x	300	
	Creosoti	℥i	32	
	Vini opii	m. xlv	3	

M. Sig. Two tablespoonfuls as an enema, mixed with the yolk of an egg and added to a tumblerful of water.

—*Pacific Medical Journal.*

Iodoform is recommended by such men as Flick, Ransom and De Renzi.

℞.	Europhen	ʒi	4	
	Olei anisi	ʒi	4	
	Olei rosæ	m. i		06
	Olei olivæ	℥iiss	80	

M. Sig. One to two teaspoonfuls rubbed into armpits or inner parts of the thighs once or twice daily.

Flick thinks europhen combined in this way with olive oil evolves nascent iodin. —*Progressive Medicine.*

℞.	Iodoformi	gr. iss		09
	Codeinæ	gr. 1/3		02
	Ext. cascaræ sagradæ	gr. 1/2		03

M. Ft. pil. No. i. Sig. One pill three times a day.

—Knopf.

℞.	Sodii cinnamatis (aqueous 5 per cent. sol.)	℥i	32	

Sig. Inject four or five drops into the gluteal region, avoiding the region of the gluteal vessels and the sciatic nerve. Repeat the injection every other day.

Oppression, chilly sensation and headache are indications for reducing the size of the dose.

℞.	Pulv. acidi cinnamici	gr. vii		5
	Olei amygdalæ dulcis	ʒiiss	10	
	Yolk of egg	No. i		
	Sodii chloridi, 7/1000, q. s. ad	℥iiiss	112	

M. Ft. emulsio. Sig. To be used as an intravenous injection into the fold of the elbow. Four to six drops to be used daily. —Landauer: *Riforma Med.*

He recommends a dose of 1/60 grain of cinnamic acid gradually increased to 1/30 every second or third day. He claims that cinnamic acid produces intense phagocytosis, and causes a sclerotic condition in the tissues in the neighborhood of the morbid growth.

℞.	Guaiacol carbonatis	gr. xv.	1	
	Strychninæ sulphatis	gr. i		06
	Resinæ capsici	gr. iii		20
	Ammonii chloridi			
	Quininæ bisulphatis, āā	gr. xxx	2	

M. Ft. capsulæ no. xxx. Sig. One every four hours.

—Stewart: *Internat. Med. Mag.*

Dr. Laborde, of Paris, calls attention to the importance of conserving the digestive capacity of the patients and recommends the following to be given hypodermically:

R.	Guaiacol	ʒv	20	
	Eucalyptol	ʒiiss	10	
	Sparteinæ sulphatis	gr. xv	1	
	Olei amygdalæ dulcis, q. s. ad	℥vi	192	

M. Sig. Begin with eight drops and inject while the patient is in bed; gradually increase the amount of the injection to six or seven cubic centimeters—ninety to one hundred minims.

—*Therapeutic Gazette.*

Gimbert used the following hypodermatically:

R.	Creosoti	m. xv	1	
	Olei amygdalæ dulcis	ʒiiiss	14	

M. Sig. Inject drop by drop intermitting occasionally to avoid pain until the full amount is injected.

The virtue of creosote depends upon its purity and especially on its freedom from carbolic acid and pyrogallol. Pure creosote has an oleaginous appearance, a strong resinous odor, a caustic taste, is slightly soluble in water, very soluble in alcohol and oils. The true virtue of creosote is chiefly nutritional. —Whittaker.

℞.	Ichthyolici			
	Aquæ destil. āā	ʒv	20	

M. Sig. Begin with four drops three times daily before meals and increase to forty drops. Children between 5 and 12 years take one half the dose. A draught of black coffee after taking it will disguise the bad taste. Cohn reports nothing but good effects from its use.

—*American Text-Book of Therapeutics.*

℞.	Creosoti	ʒss to ʒi	2-4	
	Olei amygdalæ dulcis	ʒvi	24	
	Yolk of egg, No. 1			
	Aquæ destil	℥viss	208	

M. First dissolving the creosote in the oil and subsequently emulsify with the yolk of egg. Sig. Inject per rectum at night.

The oil of sweet almonds is preferred, because it does not produce colic and because it contains matters that act as adjuvants in alimentation.

—Vopelius: *Text-Book of Applied Therapeutics.*

CREOSOTE IN THE FORM OF A WINE.

℞.	Creosoti	℥ss	16	
	Tinct. gentianæ comp.	℥i	32	
	Alcoholis	℥iii	96	
	Vin. xerici, q. s. ad	Oii	1024	

M. Sig. One dessertspoonful three times a day, provided the temperature is not too high. —*Les Nouveaux Remèdes.*

℞.	Creosoti	m. xxv	1	5
	Tinct. gentianæ	℥ss	16	
	Spts. vini rect	ʒvi	24	
	Vin. xerici q. s. ad	℥vi	192	

M. Sig. One tablespoonful three times a day.

℞.	Argenti nitratis (2.5 per cent. sol.)	℥i	32	

Sig. Inject four to seven drops in the neck over the course of the vagi, on the same side as the diseased lung. Repeat the injection once a week only.

—Thos. J. Mays: *Med. and Surg. Reporter*

Medicolegal.

Baking Powder Law Constitutional.—Chapter 245 of the general laws of Michigan of 1899 requires all manufacturers and sellers of all compounds or mixtures intended for use as a baking powder to affix a label to every box or can, containing the name and residence of the manufacturer, and the words, "This baking powder is composed of the following ingredients," "and none other"—following the names of the ingredients. This chapter is an amendment of an act of 1889, which required such a label to be put upon boxes and cans containing alum, in any form and shape, as a constitutent. And, as the Supreme Court of Michigan held the earlier statute constitutional, so now does it hold, in the case of State vs. Sherod, the enactment of 1899 valid, declaring that it is neither an infringement upon private rights nor class legislation.

Record Warranting Exhibition of Foot to Jury.—A young farmer had his foot caught in a hole in a depot platform and severely injured as he was attempting to board a train which was just at that moment moved a couple of car lengths. His ankle was dislocated, and its ligaments torn. His toes were turned around, and the larger bone of his ankle was pushed forward. It was also proved that his ankle would be permanently stiff. The jury awarded him $2000 damages. Taken to the Court of Civil Appeals of Texas, one of the points argued, Texas Midland Railroad vs. Brown, was that it was error, in the trial of the cause, to permit the party to exhibit his injured foot to the jury. But, it appearing from the bill of exceptions, and also from the statement of facts, that the condition of the foot was fully shown by the evidence, the court holds that the objection to the exhibition of the foot on the ground that it could not be set up in the record was not well taken. The Supreme Court of Texas has denied a writ of error.

Four Thousand Dollars for Colored Boy's Arm.—In the case of Jackson vs. the St. Louis Southwestern Railway Company, where it says that there is no law authorizing the taking off of a boy's arm at the shoulder as a penalty for trespassing on railroad or any other property, the Supreme Court of Louisiana holds that four thousand dollars is not an excessive award of damages for the loss of his left arm by a colored boy fourteen years of age. It says of the boy in question that he was poor, black, illegitimate, and ignorant, and when injured was receiving 75 cents a week for working about a negro barber shop, to which were added his earnings—probably a few dollars a week—as a bootblack. Continuing, the supreme court says that it seems to it that, being about as badly situated as a boy of fourteen who is not an invalid or a criminal could be, he was particularly in need of the arm of which he had been deprived; for that and the other arm were about all that he had to depend upon to help him through in the long struggle which lay before him, and which is hard enough even for those who are better situated and have both arms and hands. Hence, it holds the amount specified not excessive compensation for the boy.

Allowance for Nursing of Minor in Injury Case.—In Texas & Pacific Railway Company vs. Short, an action brought by the latter party to recover damages for the loss of his minor son's services, and for expenses incurred for nursing, medicines, and doctor's bills because of the boy's leg being broken and he otherwise injured by the alleged negligence of the railway company, objection was made to the trial judge's permitting the father to prove the price he contracted to pay for the nursing of his son. But the Court of Civil Appeals of Texas declares that it can not say that this was error. Yet, in such a case, it would be the duty of the court, if requested to do so, it holds, to charge the jury that the reasonable value of the services rendered, and not the contract price, would be the true measure of damages. In determining the reasonable value of the services, it then goes on to say, all the circumstances under which the services were rendered should be taken into consideration. And it holds that the father, if entitled to recover at all, could recover for the services of himself, of his wife, and of his minor son and daughter in nursing the injured boy. To this it adds that, while it is not prepared to say that the father could not recover therefor without so doing, under such a claim of damages as above mentioned, it would suggest that it would be better practice for the petition to allege that his minor son and daughter assisted him in nursing their brother.

A Crime Against Nature.—The Supreme Court of Louisiana says, in State vs. Vicknair, that it is incomprehensible why, in the common-law courts, the use of the mouth should not have been considered as much against nature as though the act were committed per anum. But the "crime against nature" being a common-law offense, made a statutory offense in Louisiana, and the definition of which, as known to the common law, having been adopted by statute, it was competent for the legislature, it holds, to amend the existing law, denouncing and defining the crime, by declaring, as was done by the statute of 1896, that a particular act, not otherwise so considered, as for example committing the offense "with the mouth," should, as well as sodomy, constitute said crime; though, no doubt, it says it must appear that the sexual organ of the one party or the other, either the agent or the pathic, was used. The crime here considered, the court goes on to say, is generally regarded as being governed in some respects by the principles of law which are applicable to rape. But it thinks that it can be readily understood why proof of emission might be considered necessary to establish the latter crime, and yet not be necessary to establish the former. And so, while the English courts and those of this country have been divided in opinion as to whether, in regard to rape, such proof was necessary, under the common law, the court holds here that, particularly as the enormity of this crime against nature consists solely in its utter bestiality, proof of emisso seminis is not necessary to conviction in a prosecution for it, as denounced by the statute of 1896; nor does it matter, in the case of an adult, whether he be charged as agent or pathic, so long as the particular act charged brings it within the definition of the statute.

Charges by Student Makes Practice Unlawful.—In Arkansas there is a statute which declares that it shall be unlawful for any person to practice or attempt to practice dentistry or dental surgery, in the state of Arkansas, without first having received a certificate from the board of dental examiners: provided, this shall not be construed as preventing any regular licensed physician from extracting teeth, nor to prevent any other person from extracting teeth, when no charge is made therefor by such persons. From this language, the Supreme Court of Arkansas holds, in the case of State vs. Reed, it is impossible to escape the conclusion that the performance of dental work, and charging and receiving pay therefor, is practicing dentistry. And it condemns the theory of the trial court in this case, which seemed to be that, notwithstanding this, yet, as the party accused of practicing dentistry without first obtaining a certificate from the board of dental examiners was, when he did the work in question, a mere student, and doing his work under the direction of a licensed dentist, he was not answerable to the law on the subject. It must be noted, the supreme court says, that if this is any defense at all, on which point it expresses no opinion, but makes this suggestion, while this relation existed in this case between the accused and a regular practicing dentist, so far as the dental work in question was concerned, yet the charge for the same was not made in the name of the licensed dentist, nor was the pay received by him. The charge was made by the accused for himself, independent of his preceptor, and so was the pay received by him. Under such circumstances, the supreme court holds, it was error for the trial judge to instruct the jury to the effect that if they believed that the accused was in he office of the regular dentist mentioned, and was working under the latter's directions and advice, he should be acquitted.

Postmaster General's Power to Prevent Fraud.—In the case of the American School of Magnetic Healing vs. McAnnutly, the United States Circuit Court was asked to restrain the postmaster at Nevada, Mo., from obeying a certain order issued by the postmaster general. That order directed the Nevada postmaster to return to the senders thereof all letters, whether registered or not, which arrived at his office addressed to the complainants in this suit, and to stamp thereon the word "Fraudulent," or to transmit said letters to the dead-letter office at Washington, D. C., to be disposed of as other dead matter, under the laws relating thereto, when there was nothing on said letters to indicate who were the senders of the same. This order contained a finding by the postmaster general, in accordance with the acts of congress giving him his authority in the matter, that it had been made to appear upon evidence satisfactory to him that the American School of Magnetic Healing, S. A. Weltmer, the president thereof, and J. H. Kelly, its secretary, were engaged at Nevada, Mo., in conducting a scheme or device for obtaining money through the mails by means of false and fraudulent pretenses, representations, and promises. Under these circumstances, the court holds that it could not lawfully grant the temporary injunction prayed for. It says that it is manifest from an inspection of the United States statutes bearing on the subject that congress has in express terms conferred upon the postmaster general the power to prohibit the delivery of any and all mail matter to a person whom that officer, after a due investigation, finds to be engaged in conducting through the mails either a lottery or a scheme to obtain money by false and fraudulent pretenses. Nor does the court consider the statute unconstitutional. It says that it is hardly necessary to observe that, if the right to use the mails is a statutory privilege, and not property, within the meaning of the fifth amendment to the federal constitution providing that no person shall be deprived of his property without due process of law, as is held, then no fault can be found with the statute here under consideration, because it devolves on the postmaster general the duty of ascertaining by satisfactory evidence if one is using the mails to defraud, and make his right to use the mails dependent upon that finding. Neither does it think that the courts should interfere on the ground that the power conferred on the postmaster general is of an arbitrary character, and, if erroneously exercised at any time, might occasion great loss and inconvenience to the citizen.

Rape by Boy Under Fourteen Years of Age.—The Supreme Court of Florida has reversed a conviction of rape, in Chism vs. State, where the death sentence was imposed. The testimony for the accused tended to show that he was under the age of 14 years at the time the offense was alleged to have been committed. And the court holds that it was error to instruct the jury that, if they believed from the evidence that the accused was under the age of 14 years a presumption arose that he was incapable of committing the crime, and that this presumption continued until the state by competent testimony overcame it, and established capacity by showing that he had reached the age of puberty to the exclusion and beyond a reasonable doubt. It says that the rule of the common law is that a boy under the age of 14 years is conclusively presumed to be incapable of committing the crime of rape; and this rule, it holds, is still in force in the state of Florida. All the American courts, without exception, it says, admit that, at common law as administered in England, a boy under 14 years old could not commit the crime of rape, not because he had not then arrived at the age of discretion to discern right from wrong, but because he was deemed to be physically incapable of committing the particular crime of rape. But several American courts, it continues, have refused to apply absolutely the common-law rule in their respective jurisdictions, on the theory, it would appear from the reasoning employed, that, as the rule originated in England under climatic and other conditions surrounding the English people showing that puberty did not develop in males before the age of 14, it should not be rigidly applied here, where experience frequently shows a development of puberal capacity before that time. In other words, the common-law rule, according to this view, is deemed sufficiently flexible to admit of application to actual facts as they may be shown to exist, and so it is laid down that before the age of 14 a presumption exists of incapacity, but that it may be overcome by proof. This doctrine impresses the court with merit, and it says that it is not at all surprising that some of the courts in this country have adopted it. Yet, where, as in Florida, the common law of England in relation to crimes has been adopted by statute, and there is no enactment on the subject of the age under which a male can not commit the crime of rape, the courts, the Supreme Court of Florida holds, are not authorized to set the common-law rule aside for the reason that the climatic or racial conditions of the people differ from those of England, where the law was developed. If such conditions demand a change of the common law, it is for the legislature to make it and not the courts.

Societies.

Coming Meetings.

American Public Health Association, Indianapolis, Ind., Oct. 22-26.
Medical Society of Virginia, Charlottesville, Oct. 23.
Southern Surgical and Gynecological Association, Atlanta, Ga., Nov. 13-15.
Oklahoma Territory Medical Society, Oklahoma City, Nov. 15.
The Tri-State Medical Association of Mississippi, Arkansas and Tennessee, Memphis, Nov. 13-15.
Indian Territory Medical Association, Muscogee, Dec. 4-5.

The Fresno County (Cal.) Medical Society met at Fresno, October 2. Dr. J. H. Parseghian read a paper on the "Treatment of Rheumatism."

The Springfield (Ohio) Academy of Medicine recently held its second meeting of the season, when Dr. M. V. Patton read an article on "Medical Ethics." Dr. Louis L. Syman presented a case of musical heart.

The Columbus (O.) Academy of Medicine, at its session, October 1, listened to and discussed papers by Dr. Herbert M. Platter, on "The Recent Epidemic of Smallpox in Columbus" and "The Diagnosis of Tubal Pregnancy Before Rupture."

The Cambridge (Mass.) Medical Improvement Society met for its regular monthly session, September 24, and listened to a paper by Dr. Joseph S. Lockhart on "Infantile Hemiplegia" and a report by Dr. Walter J. La Marche of two interesting abdominal cases.

The Orange County (Cal.) Medical Association held its October meeting on October 2, at Westminster. Dr. H. S. Gordon presented a paper on "Pelvic Inflammation"; and Dr. F. E. Wilson one on the "Microscope in Diagnosis." The next meeting will be held in Santa Ana.

The Fairfield County (Conn.) Medical Society held its one hundred and eighth semi-annual meeting at Westport Sanatorium October 9. Papers were read by Dr. William B. Coley, New York City, on "Female Hernia," and Dr. J. Murray Johnson, Bridgeport, on "Pulmonary Surgery."

The Clinical Society of Washington, D.C., met after the summer vacation, on October 8, and elected the following officers: Dr. Charles C. Marbury, president; Dr. Duff G. Lewis, vice-president; and Dr. J. Carlisle De Vries, secretary and treasurer. Dr. Wallace Johnson read a paper on "Clinical Pathology," which was discussed by many of those present.

The Clinton County (Ia.) Medical Society held its quarterly meeting at Clinton, October 2. A paper was read by Dr. Harry R. Reynolds on "Specific Tertiary Lesions." A paper was also presented by Dr. Robert E. Everhart on "Rheumatism," and Dr. John F. H. Sugg opened a discussion on the "X-Ray in its Medico-Legal Relations."

The Lucas County (O.) Medical Society met at Toledo, October 5. Dr. Clarey E. Stewart read a paper entitled "The Doctor," and Jesse L. Baird read a paper on "Mercurials—Some of their Attributes and Uses." A general discussion on "Should Chloroform and the Obstetric Forceps be Used More Freqeuntly in Labor Cases?" then took place, which was opened by Drs. Watson, Gillette and Strausz.

The Madison County (Ind.) Medical Society held its quarterly meeting at Pendleton, October 2. Papers were read by Dr. John B. Fattic, Anderson, on "Treatment of Electrical

Injuries"; Dr. Anthony E. Otto, Alexandria, on "Hay-Fever and its Treatment," and Dr. Frank P. Nourse, Alexandria, on "Pelvic Inflammation." Dr. John W. Cook, Pendleton, gave some reminiscences of a recent trip abroad.

The Denver and Arapahoe (Colo.) Medical Society met in Denver, October 9. Papers were read by Dr. Francis H. McNaught on "The Treatment of Puerperal Infection"; by Dr. Horace G. Wetherillon, "The Prevention of Puerperal Septicemia," and by Dr. Charles A. Powers, on "The Surgical Importance of Apparently Simple Carbuncles and Furuncles of the Upper Lip" and "Abdominal Testicular Ectopia, Associated with Inguinal Hernia-Management."

The Thurber Medical Association held its 47th annual meeting at Milford, Mass., October 4. The officers elected for the ensuing year were: President, Dr. Nathaniel C. B. Haviland, Holliston; vice-president, Dr. Ralph C. Fish, Hopedale; secretary, Dr. John M. French, Milford; treasurer, Dr. Le Grand Blake, Milford. The prize for the best paper read during the year was voted to Dr. John M. French, Milford, for his paper on "The Treatment of Acute Croupous Pneumonia." The anniversary address was delivered by Dr. Wilfred W. Browne, Blackstone, on "The Lights and Shadows of a Physician's Life."

The Southwestern Tri-State Medical Association, composed of physicians from Texas, Oklahoma and Indian Territory was organized at Dallas, Tex., October 1. Dr. Vene P. Armstrong, Dallas, was elected temporary chairman, and Dr. John O. McReynolds, Jr., Dallas, temporary secretary. The code of ethics of the American Medical Association was adopted. The following officers were elected: Dr. Henry K. Leake, president; Dr. J. W. Lowe, Holdenville, I. T., first vice-president; Dr. Charles R. Hume, Anadarko, Okla., second vice-president; Dr. Hugh L. McNew, Honey Grove, Tex., third vice-president; and Dr. Samuel E. Milliken, Dallas, secretary and treasurer.

Mississippi Valley Medical Association.

Twenty-sixth Annual Meeting, held at Asheville, N. C., October 9-11, 1900.

President Dr. Harold N. Moyer, Chicago, in the chair.

Addresses of Welcome on behalf of the city, state and local profession were delivered by Hon. Theo. F. Davidson and Dr. John H. Williams.

PRESIDENTIAL ADDRESS.

Dr. Moyer referred to matters of general interest to the profession. He alluded to an address which was delivered at the recent International Medical Congress by a distinguished American colleague, who saw fit to discuss the old code question. The speaker (Dr. Moyer,) thought it unfortunate that this subject, long since dead, but not buried, should be embalmed in the records of that Congress. The medical profession of America does not need an apologist for its standard of medical education to-day, and in support of this contention the speaker quoted from an editorial in the *London Lancet* of comparatively recent date.

As to medical societies, there can not be too many of them. In no other country are they so numerous as in America. Abroad these societies are for the few; in this country they are for the many, and it is to their collective voice, speaking in no uncertain tones, that the profession owes the uplift of medical education.

The speaker then discussed the relation of the profession to the law. The passage of medical-practice acts has been urged by the medical profession, and physicians have been distinctly misunderstood in their attitude toward such legislation. Legislators feel in some way that the medical profession wishes to put a fence around the practice of medicine and that physicians, being on the inside, may fatten on it. This is not true. Physicians do not urge the passage of medical-practice acts for their personal aggrandizement, but simply to protect the people, to prevent the illegal practice of medicine by unqualified persons and by quacks.

If anything can be said in criticism of the medical profession in this country, it is the overweening inclination toward specialism. The physician should spend several years in general practice before adopting a specialty. Specialism has wrought great good for medicine, but the profession should see that it is not overdone. If a physician desires to acquire a broad general culture, it can only come from general practice. The selection of a specialty should, like matrimony, come naturally, and without being forced.

ABDOMINAL VERSUS VAGINAL HYSTERECTOMY.

Dr. H. O. Walker, Detroit, Mich., read a paper on this subject. The question of the best approach surgically to the uterus and adnexa has not been settled, judging from the amount of discussion of late on this topic. Cancer of the uterus is not an infrequent cause of death in women. The recurrence of cancer of the uterus is very important and is immediately connected with the method of its removal. The manner of recurrence of cervical cancer is either by extension into the broad ligaments, vagina downward, and other contiguous parts, as the bladder and rectum, and occasionally the body of the uterus; or by metatases, through the lymph-channels and by distant direct implantation. The surgeon is to be governed by the method of operation that will offer the best advantages in avoiding a recurrence of the disease, and in order to illustrate the two routes he reported two interesting cases, in one of which he could not have operated as successfully by the vagina as through the abdomen. In the other case the vaginal route was indicated, and this operation was done. All things being equal, the abdominal route offers a more complete hysterectomy than the vaginal method. 1. The surgeon is better able to see what he is doing. 2. He can control hemorrhage more efficiently and completely than by the vaginal route, where he is working in a dark cavity. There is less liability of slipping of the ligatures, and if they should slip, they are reached more easily than by the vaginal section. 3. The danger to the ureters is minimized, and, if injured, the opportunity for their repair is much better; while if they are injured by the vaginal route, the surgeon would have to do an abdominal section to effect repair. 4. The prevention of sepsis is more certain by the abdominal than by the vaginal route, aided, in the former instance, by the Trendelenburg position, which gives opportunity for full protection of the intestines and peritoneum; while in the latter the opportunity for protection is limited, as it is an impossibility to secure perfect asepsis in the vagina where there has been a long-standing infective disease.

CANCER OF THE UTERUS AND ITS TREATMENT.

Dr. R. S. Sutton, Pittsburg, contributed this paper. Cancer operations should not be recommended as curative, but as palliative and therefore useful. Total vaginal extirpation of the uterus at or after time of climacteric, should find a place as prophylactic treatment against cancerous disease. This paper consisted of a compact review of the anatomy, pathology, diagnosis and present method of treatment.

The author expressed the opinion that treatment for existing cancer of the uterus had probably reached its complete evolution. In view of the ultimate results of this treatment, which he heartily endorses, because there is none other known to take its place, he asks the question, cui bono?

He then discussed the question of prophylaxis, and showed that the average age of his patients operated on was 43 years and a fraction, and claims that if these patients had all been subjected to total vaginal extirpation, at the average age of 40 years, all of them would have escaped cancer of the uterus; that according to his own statistics, but 4 per cent. of the cases would have died; whereas, nearly 100 per cent. of the cases did die, within a period of two or three years, after operations for cancer.

He urged greater attention to the early repair of lacerations of the cervix, and a more painstaking observation, and consideration by physicians at large of that train of symptoms preceding, and leading up to, the development of cancer of the uterus. He unequivocally recommends radical surgical treatment in all such cases, and clearly announces that if we are to diminish the number of uterine cancer cases, and consequent mortality in the future, it must be done in forestalling the disease.

In the discussion, Dr. Edward W. Lee, St. Louis, favored the abdominal route in the majority of cases, for the reason that it is easier of performance; the surgeon can see what he is doing; he has a more perfect control of the tissues, and can do a more thorough operation. The only condition in which he believes the vaginal operation is justified is in cases of small, uncomplicated fibroid tumors of the uterus which can be easily shelled out.

Dr. Chauncey D. Palmer, Cincinnati, said that until within the past few years the vaginal method was preferred to the abdominal. It is important in cases of cancer of the uterus that all of the diseased structure be removed; consequently this can be done more easily and thoroughly by the abdominal route.

Dr. J. Wesley Bovee, Washington, mentioned three classes of cancer of the uterus, where the removal of whatever other structures may be involved, is advisable. In very feeble patients, who are not able to stand a prolonged or tedious operation, he favors the combined method advocated by Ries, Clark, Werder and others. He has done the combined operation in 13 cases, all of whom are living, with 2 recurrences.

Dr. A. H. Cordier, Kansas City, Mo., said, in cases in which there is extensive involvement of the cervix by the cancerous process, as involvement of the bladder and rectum, patients derive much benefit by a thorough curettage of the cancerous mass, then the Paquelin cautery, and packing of the parts with carbid of calcium. Along with this he uses the old Goodell injection (vaginal) of permanganate of potash.

Dr. Hugh A. Cowing, Muncie, Ind., urged upon the general practitioner the importance of making an early diagnosis of cancer of the uterus.

Dr. William F. Barclay, Pittsburg, thinks the general practitioner is blamable for not referring cases of cancer of the uterus early to specialists. For years he has made it a rule, when in doubt as to the diagnosis of disease of the uterus, particularly when the patient complained, to refer the case to a specialist, and has been satisfied with the results.

POST-OPERATIVE INTERNAL HEMORRHAGE.

Dr. A. H. Cordier, Kansas City, drew the following deductions: 1. In diagnosing post-operative hemorrhage the history of the patient will aid much. 2. Symptoms of shock and hemorrhage are very similar. 3. In suspected cases a single stitch in the incision cut will tell. 4. In cases in which bleeding is anticipated, a tube should be used. 5. The surgery must be quick and decisive in these cases. 6. Large quantities of normal saline solution will save many cases. This should be used both per rectum and into the veins. 7. Strychnia, belladonna, etc., will not control bleeding from the uterine or ovarian artery any better than from the radial or temporal. 8. The surgeon should do what his surgical conscience tells him is right.

INTERMITTENT HYDROPS OF THE KNEE.

Dr. George W. Cale, Springfield, Mo., reported the case of a woman 45 years of age. The first appearance of her trouble began five years ago. There was no history of injury. There was a rapid accumulation of fluid in the left knee-joint, but which was not painful. This disappeared in from one to four weeks, with or without treatment. The disease would recur at periods varying from one to six months.

VENTRAL HERNIA FOLLOWING LAPAROTOMY.

This paper was read by Dr. B. Brindley Eads, Chicago. The occurrence of ventral hernia as a sequence of abdominal section is so common that it should command thoughtful consideration. The author urged the adoption of those methods which personal experience has demonstrated to be of the greatest use, both immediate and remote. He quoted Greig-Smith as saying that ventral hernia is a mere stretching of scar tissue, but the essayist regards it as a stretching not only of the scar tissue, but of all of the tissues of the abdominal wall at the site of its occurrence.

As intact innervated muscular fiber is the only safeguard against hernia following laparotomy, the first rule is to make the abdominal incision parallel, or nearly so, with the direction of the motor nerves, and of the most important muscular fibers supplied by these nerves. In considering the incision the following points must be taken up: 1. The length is largely dependent on the thickness of the superficial fascia; it must be sufficient to allow free access to the muscles whose functional integrity is essential to success. 2. The length must be relatively greater than when muscular fibers are to be separated instead of divided. 3. It must vary with the pathological condition for which the operation is performed. 4. An opening of sufficient size must be secured for thorough exploration and to obtain the requisite degree of precision and rapidity in manipulation. 5. A long incision through the skin and superficial fascia does not predispose to hernia. 6. It lessens the mortality by providing ample space for the protection of surrounding viscera. 7. It lessens shock by diminishing the time required for the operation, and also the duration of the anesthesia.

Several incisions were mentioned by the essayist. The difficulties he has experienced in reaching the appendix through the McBurney incision in acute suppurative cases of appendicitis have caused him to devise another method of approach in a more dependent part. This incision overlies the outer border of the cecum and leads directly to the appendix. It is slightly curved outward and downward, crossing an imaginary line drawn between the anterior superior iliac spines. The center of this curve is from an inch to an inch and a half to the inner side of the right superior iliac spine. The skin and superficial fascia are incised for about two inches. This freely exposes the aponeurosis of the external oblique, which is separated by means of the dry dissector, or the handle of a scalpel, in the direction parallel to its fibers, and well retracted. This brings into view the transversely arranged fibers of the internal oblique and transversalis muscles, and the twelfth abdominal, ilio-hypogastric, and possibly the ilio-inguinal, nerves which are in turn retracted in order to reach the transversalis fascia, which, together with the peritoneum, is divided transversely. The advantages gained by this incision are: 1. It provides easy access to the diseased area. 2. It enables the operator accurately and securely to protect the peritoneal cavity from infection. 3. It lessens liability to breaking down the inner limiting wall of adhesions. 4. It affords a better opportunity to open the abscess cavity from the outer side. 5. It favors drainage. 6. It has not been followed in the author's experience either by appendicular fistula or post-operative hernia.

GANGRFNE OF THE SCROTUM AND PENIS.

Dr. E. H. Richardson, *Atlanta, Ga.*, narrated the history of a case which showed the initial lesion to have been an abrasion of the skin near the os pubis, with probably infection from the erysipelatous cocci at this point, and later a mixed infection from the streptococcus of gangrene, terminating in the destruction of the gangrenous process of the entire integument of the penis and of three-quarters of the scrotum. A plastic operation was made, with the result that the integument of the penis and testes was preserved. The patient made a perfect recovery.

TRACHELOPLASTY.

Dr. Henry P. Newman, Chicago, read a paper on this subject. In order to maintain a condition of normal health in the body, it is necessary that all of the organs properly perform their functions. The author calls attention to the great importance of the function of the cervix uteri in relation to disease in women. In former times cervical lesions were recognized as a fruitful source of gynecic evils, and many operations and instruments were devised for their correction. Emmet's trachelorrhaphy, once so popular, has ceased to be adaptable to the needs of to-day in repairing cervices. Dr. Emmet, in conceding this himself, and offering amputation as a substitute, states that the great advance in the obstetrical art and the methods of caring for a lacerated cervix in labor have altered the character of surgical pathology, so that trachelorrhaphy, as formerly practiced, is rarely called for.

The author finds the indications for plastic work on the cervix still widespread enough to justify the presentation of a new method of operating. This he calls tracheloplasty, it being plastic work designed not only to restore normal contour and relation, but to re-establish proper function. The distinctive features of the methods are the use of a specially designed knife, the shape of the flaps in the anterior and posterior lips of the cervix, clean, smooth-cut surfaces, accurate approximation of flaps, the certainty of restoring the proper lumen of the canal, and the simplicity of the after-treatment. Neither tracheloplasty, nor any one operation of the kind, should be relied on to correct all the ills which accrue from lacerations in child-bed. It is frequently necessary to do such simple work as shortening the round ligaments, or suspensio uteri, where there is a displacement of the uterus; divulsion and curetting where disease has extended to the endometrium above; reparation of the pelvic floor where, through relaxation or trauma, there is a hernial condition of the rectum, bladder, vagina or superimposed viscera; sometimes even the opening of the abdomen for plastic work, or resection of pathological conditions of the ovaries, tubes, etc. Any one or two of these accessory operations may be necessary to restore the patient, although the disease or deformed cervix may have been the essential, perhaps the sole, etiological factor in the case.

MIDDLE-EAR DISEASE IN ITS RELATION TO THE CRANIAL CAVITY.

Dr. O. J. Stein, Chicago, read a paper on this subject, in which he pointed out the necessity of recognizing the importance of possible intracranial complications in every case of middle-ear disease. The various avenues of infection were dwelt on at length, these being illustrated by beautiful drawings and specimens. The symptomatology of intracranial phlebitis, thrombosis and abscess was discussed, and several instructive cases reported. In connection with this paper, Dr. J. Holinger, Chicago, gave an interesting stereopticon demonstration.

ADDRESS IN MEDICINE.

Dr. I. N. Love, New York City, selected for his subject, "Nutrition and Stimulation." Continuance of life, beginning with the original protoplasm, the cell, depends on proper nourishment. The recognition of this fact is essential in all the work of the physician. The proper nutrition of the new being, from the very beginning, prior to birth, should be carefully looked after by the careful physician. After birth the security of the infant depends on the proper appreciation of its proper feeding. From infancy to maturity this should be the essential thought of the parent and the doctor, who should ever realize his importance as the helper of the parent in the building-up of a complete man or woman. The entire scheme of tissue-building, of repair, of maintenance of the mechanism of the human body involves not only nutrition, but perfect elimination, and the two together are expressed in the term metabolism. Interrupted metabolism tends toward organic disease, and finally death. Perfect metabolism means perfect health.

Stimulants are of value, if used in the right way and at the right time. In the healthful condition they are not needed. They are essentially a luxury. All luxuries should be used with the greatest care, and only the thoroughly healthy can indulge safely in luxuries. Stimulants are divided into two classes, namely, those that are exclusively remedial, and those that come under the head of luxuries associated with everyday life. Of all the stimulants, alcohol stands first. It is probably the most prompt diffusible stimulant we have. There are arguments for and against alcohol as a food.

Coffee and tea are essentially domestic pleasures, and while seemingly harmless, they are potent whippers-up of energy and should be used with great care. Tobacco has never been thought of as a food. It is primarily a stimulant, but, like all other stimulants, it is secondarily a depressant. It is a luxury, pure and simple. Morphin, cocain and others of their class are of great value to the profession, but improperly used are more deadly in their effects than the scalpel in the hands of the unskillful.

TREATMENT OF PERIRECTAL ABSCESSES.

Dr. John L. Jelks, Memphis, Tenn., read a paper on this subject. Rectal abscesses, when properly treated, are not so serious as when it was the practice to use poultices and await pointing. These abscesses need not result in fistulæ, unless they are the result of malignant diseases, as tuberculosis, cancer and syphilis. The fault to be found in a simple incision and drainage of these abscesses is that their walls are not gotten rid of; hence this barrier to general infection or infection of other and deeper structures remains to continue an irritation and to cause suppuration. In many cases the abscess wall becomes calloused, and all efforts to establish granulation are futile. When he is able to elicit fluctuation, he opens freely and hastily irrigates through an irrigating curette, attached to a fountain syringe, until the irrigating fluid comes away free from debris; then with a sharp irrigating curette he removes all of the abscess wall, thereby converting the cavity into a surgical wound. He uses formalin solution in irrigating these cavities and packs them with iodoform gauze. After thus treating these cases he expects no further suppuration. Since using formalin solution in irrigating these cavities he has, in the after-treatment of them, seldom noticed any suppuration.

Superficial abscesses should be dealt with in the same manner; or they may be frozen and excised as the surgeon would a tumor. They are, when otherwise treated, liable to infect deeper structures. Local anesthesia will suffice, and curettage can be properly practiced with it. If the wound is painful, or the formalin solution irritating even when very dilute, antibrule in 50 per cent. solution is to be preferred. In rectal surgery he has not found the objections to the use of formalin which have been referred to by rhinologists and laryngologists.

SIMPLE OPERATION FOR HEMORRHOIDS: ENUCLEATION.

Dr. J. Rawson Pennington, Chicago, contributed this paper, which was profusely illustrated. He gives a cathartic the second night before the operation, a saline the following morning and a bath, and colonic flushing the night before. The next morning he gives an enema of from one-half to one pint of cool water, and operates two hours later. He emphasizes the importance of carefully examining the entire rectum. He grasps each anal quadrant at the muco-cutaneous junction with a pair of forceps; the anus is everted, and the internal tumors exposed. Seizing with the hand the forceps attached to the posterior quadrant, he fully everts it, and, with a pair of scissors curved on the flap, cuts off the redundant membrane only, which is usually about one-third or one-half of the uppermost part of the hemorrhoidal node. This permits the blood in the tumor to escape. All of the angiomatous tissue is carefully removed, when the remaining wall collapses. Each quadrant in regular order is treated in a like manner. A stream of hot sterilized water flows over the field continuously during the operation. Spurting vessels, if any, are caught with forceps and thoroughly twisted. Should this fail to control hemorrhage, he throws a ligature around the vessel and ligates it. The operation having been completed, he introduces a rubber-covered tampon, which has been fully described in previous articles by the author.

The advantages of this method are: There are no stumps to slough, nor nerves caught and squeezed, which will cause excruciating pain, as when the ligature is used; nor are the nerves and tissues burned to a crisp, as when the clamp and cautery are employed. The formation of stricture is obviated.

The patient is given a cathartic and the tampon painlessly removed at the end of forty-eight hours. There is no pain nor bleeding with the movement of the bowels. After the bowels have moved the patient is instructed to keep them soft for two or three weeks by taking compound licorice powder or Apenta water, the latter being very palatable and effective. He has performed this operation in fifty cases, with more satisfactory results than he has obtained by any other method.

OBSTIPATION.

Dr. Sterling B. Taylor, Columbus, Ohio, read this paper. Obstipation was defined, and a comparison of obstipation, constipation and costiveness made. The causes of obstipation were dwelt on and classified. Hypertrophy of the rectal valve was emphasized as the usual cause of obstipation. The essayist defended the views of Martin and his method. The symptomatology of the affection and palliative and radical treatment were discussed, the author closing his paper with the citation of several cases.

TUBERCULOSIS OF THE SPINE.

Dr. Alexander C. Wiener, Chicago, contributed a paper on this subject. He made a plea for early diagnosis before deformity is noticeable. Extension and hygienic treatment are essential in avoiding complications, such as paresis and gravitation abscess. He exhibited a specimen which illustrated the possibilities of forcible correction of the spine. He narrated cases of psoas abscess in which he had effected a cure with injections of concentrated carbolic acid.

MEDICAL AND SURGICAL TREATMENT OF ACUTE AND CHRONIC CERVICAL LYMPH NODES.

Dr. Horace H. Grant, Louisville, dwelt on the purpose and function of the lymphatic glands. He showed how they may be rendered useless and harmful by disease and disintegration. He pointed out the limitations of medical and expectant treatment, and outlined the indications for the various surgical procedures.

ADDRESS IN SURGERY.

Dr. Charles A. Wheaton, St. Paul, chose for his subject "Fulminating Appendicitis." He said that every case of appendicitis is and by rights ought to be considered surgical, because the surgeon's training specially qualifies him to best interpret the meaning of the symptoms encountered. Every case of so-called fulminating appendicitis should be operated on as soon as its distinctive characteristics are known. High temperature and accelerated pulse, associated with local pain and rigidity, are strong presumptive evidences of malignancy in the attack, and if associated with vasomotor disturbances, are practically proof positive of perforation. The surgeon who refuses the only chance that drainage may give even the most desperate cases is false to himself, and fails materially in discharging his obligations to his patient, obligations which the patient has a right to expect at his hands. A puncture in the median line, in the loins or, in a woman, in the posterior cul-de-sac, under local anesthesia, does not add to the danger of the condition, and it materially aids nature in the awful uphill fight. In short, in every fulminating case, operate first and philosophize afterward.

SUBARACHNOIDEAN INJECTIONS OF COCAIN FOR OPERATIONS BELOW THE DIAPHRAGM.

Dr. Carl H. Andersen, Chicago, referred to the work of Tuffier, Bier and others in this comparatively new field, saying that sufficient credit had not been given to Leonard Corning as the originator and adviser of this method of anesthesia. He described its technique, which is substantially that outlined by Tuffier, and reported six cases in which he had resorted to the method.

Case 1.—Hydrocele, with vague history. Patient, colored, 28 years of age, strong and healthy. Subarachnoidean injection of 15 minims of 2 per cent. solution of cocain. Anesthesia complete. On opening the scrotum sarcoma of the testicle was found and removed. Ninth day after operation patient died from pulmonary embolism.

Case 2.—Varicose veins of the leg. Injection of 8 minims of 2 per cent. solution of cocain. Anesthesia lasted five hours and ten minutes. No pain during operation. Perfect recovery.

Case 3.—Trachelorrhaphy. Cocain anesthesia. As soon as operation was finished the patient fainted and remained in that condition for two hours. Under strychnia and salt water per rectum she rallied and recovered.

Case 4.—Amputation of toe in a man 72 years of age. Seven minims of 2 per cent. solution of cocain injected. Uninterrupted recovery.

Case 5.—Operation for suppurative appendicitis. Patient, woman. Operation performed at 10 a.m.; at 2 p.m. patient showed symptoms of medullary irritation, pain in the back, and severe headache. It is now several days since the operation was done, and patient has had a terrific headache ever since.

Case 6.—Version and use of forceps. At the suggestion of Dr. Harold N. Moyer, Dr. Andersen injected 16 minims of a 4 per cent. solution of eucain B in this case, with very satisfactory results. Patient suffered no pain whatever. Eucain B can be perfectly sterilized by boiling.

Dr. Andersen spoke of the difficulties attending the sterilization of cocain, and outlined a method by which this can be accomplished. He regards lumbar puncture as a serious operation, and urged practitioners to be exceedingly cautious in employing it. These cases were reported for the express purpose of warning the profession that the method is far from harmless, and if it is employed indiscriminately it will lead to disastrous consequences.

Dr. Harold N. Moyer, in the discussion, said that if advised as to the use of this method of anesthesia, he would say, do not use it. No surgeon should undertake it unless he has a well-equipped laboratory. The method is at best in its experimental stage, and further research and experiments should be carried on in well-equipped clinics until the possible dangers of this method are better and more clearly understood. Among the dangers are the toxic properties of the cocain. A 4 per cent. solution of eucain B can be used with absolute safety. It is about one-third as toxic as cocain and one-half as anesthetic as cocain, but it can be absolutely sterilized. The danger of infection from such injections is considerable, and should not be overlooked. As to the remote dangers from this form of anesthesia, cases have not been observed sufficiently long to enable surgeons to say whether or not there are such dangers.

TREATMENT OF TUBERCULAR AND PURULENT HIP-JOINT DISEASE WITH LARGE SPECULUM DRAINAGE AND PURE CARBOLIC ACID.

Dr. A. M. Phelps, New York City, read a paper with this title. All abscesses, tubercular or purulent, should be opened as soon as the diagnosis is made, for the purpose of exploration; secondarily, for drainage, and for any surgical procedure which may be deemed advisable. Excisions should be performed when the acetabulum is extensively diseased, the diseased tissues removed, and the joint thoroughly washed out with pure carbolic acid, then with pure alcohol, and finally with a 2 per cent. solution of carbolic acid, and as large a drainage-tube of glass, as the wound will take, should be inserted. Through this large drainage-tube the packing for drainage purposes can be made. The large glass speculum enables the operator to watch every pathological change which takes place throughout the wound. It keeps the soft parts widely separated, and prevents their union until after the bone has granulated up and healed. It enables the operator to dress his patient without doing violence to the granulating surfaces of the wound, and inflicting unnecessary pain. All rubber drainage-tubes should be entirely discarded, as they are filthy, collapsible, and are a source of infection. The carbolic acid is absolutely neutralized by the action of the alcohol. Local carbolic poisoning, and even when the drug is taken internally, is neutralized by the action of the alcohol. Pure carbolic acid applied locally is a specific for erysipelas, the points of which were brought out in the paper.

PULMONARY TUBERCULOSIS IN INFANCY AND CHILDHOOD.

Dr. Frank P. Norbury, Jacksonville, Ill., said that this disease is not a rarity among children, as the utilization of available post-mortem material shows. Heredity is of etiological importance, but it has lost its prestige as compared to its former standing. Modern scientific inquiry has shown that infection is the etiological factor par excellence. Direct heredity can account for a limited number of cases. The infection theory is proved by the lateness of the appearance of disease; few cases occur during the first year of life, and steadily increase thereafter. The mode and route of infection are important considerations. Northrup, Carr, and others have shown that tuberculosis starts more frequently in the thorax than elsewhere. Pulmonary affections, such as whooping-cough, influenza, etc., create favorable conditions for infection. Enterocolitis and gastroenteritis create portals for intestinal infection. Milk is a source of infection; like [illegible] lous

The diagnosis may be confounded with cases of malnutrition. Bovaird says two evidences of early invasion are "progressive emaciation, not explained by other disease; continued elevation of temperature similarly conditioned." Differential diagnosis from bronchopneumonia can be made only by laboratory methods. Acute miliary tuberculosis and bronchopneumonic tuberculosis are most frequently found in infants and children.

The complications are meningitis, empyema, and involvement of bones. The prognosis is grave in most all cases, but lesions of lungs may heal under favorable conditions. With reference to treatment, prophylaxis during infancy should include attention from birth, if mother is tuberculous; also good hygienic, open-air treatment; climatic change, when possible. The symptomatic care should be the same for children as for adults. Good nutrition should be maintained, and as little medicine given as possible. Creosote is recommended by the author, also simple tonics.

THE PHYSICIAN AS A SANITARIAN.

Dr. Hugh A. Cowing, Muncie, Ind., read a paper on this subject in which he discussed preventive medicine; hygiene of infection; the physician as a factor in the spread of infection; the physician and the health officer; health legislation, and the physician and the public schools.

THE PHILOSOPHY OF THE SCIENCE AND ART OF MEDICINE.

Dr. William F. Barclay, Pittsburg, said that thoughtful minds should be engaged in ascertaining truth from falsehood. True and false philosophy should be appropriately applied to results obtained in rational conclusions. The philosophy of medicine is the comprehension of the truth in the investigation of the science, enabling one to arrive at rational conclusions in the study of physical laws which govern organized matter in their normal and pathological condition.

ASTHMA.

Dr. B. Alexander Bate, Louisville, stated that Loomis, Trousseau, Salter and others, have considered asthma a diathetic neurosis. Haig attributes it to the effect of uric acid on the circulation in the thorax. Modern opinion seems to regard asthma as a neurosis of the pulmonary plexus. In bronchial asthma uric acid in the blood so alters nutrition as to cause a neurosis of the branches of the pulmonary plexus, thus inducing hyperesthesia and engorgement of the bronchial mucosa, spasmodic contraction of the muscular fibers, and the various manifestations of metabolism. Asthma frequently alternates with such diseases of the arthritic diathesis as neuralgia, migraine, angina, and gout. Clearing the blood of uric acid has relieved asthma only to be followed by gout, as the uric acid was precipitated into the tissues. Asthma may be said to belong to the class of uric-acid diseases due to the effect of high arterial tension in contradistinction to those produced by precipitation of urates into the tissues. Cases are recorded in which mediastinal tumors pressing on the pneumogastric nerve continuously first cause asthmatic paroxyms during the alkaline tide. Pressure explains the neurosis, and the time of the paroxysm manifests the uric acid. Modern treatment has been able to cut short the attacks in most instances, and often to prevent their return. Prophylactic treatment should embrace proper hygiene and diet. Prophylaxis should be begun in the children of lithemic individuals. The therapeutic measures embrace the care of the attack and treatment during the interval. After the removal of the exciting cause the treatment consists in the use of such remedies as overcome arterial tension by freeing the blood of uric acid. The treatment of the interval consists in the use of such drugs as eliminate uric acid from the system, and the adherence to such a diet as permanently keeps down arterial tension. Rational treatment, based on the theory of uricacidemia as the chief factor in the production of asthma, has been most satisfactory in the hands of the essayist.

CURABILITY OF INEBRIETY BY MEDICAL TREATMENT.

Dr. T. D. Crothers, Hartford, Conn., said that inebriety is a neurosis, usually self-limited, and very largely curable. The craze for drink is symptomatic. The real causes are central nerve irritation, exhaustion, poisoning, and starvation. The success of the treatment depends on accurate knowledge of the causes and conditions present in each case, and the accurate application of general means and measures for their removal. Each case requires special means and measures, particularly adapted to meet the conditions present. The family physician as well as the specialist should treat these cases successfully.

FURTHER OBSERVATIONS ON THE CLINICAL APPLICATION OF THE SUPRARENAL CAPSULE.

Dr. W. H. Bates, New York City, regards the aqueous extract of the suprarenal capsule as the most powerful astringent hemostatic, and heart tonic known to the profession. It lessens congestion of the eye and of other organs. The extract is not irritating or poisonous, and, unlike other powerful drugs, is never in his opinion contraindicated. In short, the profession has no remedy which is so useful in all forms of inflammation.

CLINICAL VALUE OF PURGATIVE MINERAL WATERS.

Dr. Edwin Rosenthal, Philadelphia, discussed this subject. He spoke of natural and artificial mineral waters; simple, thermal, common salt, or muriated waters. He dwelt on the waters mostly met with in commerce, spoke of their chemistry, names, mode of action, uses, method of selection of a special purgative water, etc.

WHAT THE LAW REQUIRES OF A SURGEON.

Dr. Dudley S. Reynolds, Louisville, stated that a surgeon must possess a reasonable familiarity with the science of his profession; he must exercise reasonable skill for the locality in which he practices, and must devote due diligence and care in attending to his patient. If the patient declines to submit to that treatment which in the judgment of the surgeon is most appropriate, and he does not abandon the case at once, he assumes liability for the result of failure to do that which in his judgment was best for the relief of the patient.

DIFFERENTIAL LEUCOCYTOSIS.

Dr. L. H. Warner, Brooklyn, read this paper. Experiments in recent times have given us a better insight into leucocytosis. It has been demonstrated to be due to three causes—digestion, inflammation, and infection. Physiological and biological experiments have proved that by means of medication a true picture of leucocytosis may be produced, but which in reality represents leucocyto-diuresis, a condition very desirable in the treatment of disease and a recognition of which is of the greatest value when hematology is called on to aid in arriving at a correct diagnosis.

The following officers were elected for the ensuing year: President, Dr. A. H. Cordier, of Kansas City, Mo.; first vice-president, Dr. Charles F. McGahan, of Aiken, S. C.; second vice-president, Dr. Charles L. Minor, of Asheville, N. C.; secretary, Dr. Henry E. Tuley, of Louisville, Ky., re-elected; treasurer, Dr. Dudley S. Reynolds, of Louisville, Ky., re-elected.

Put-in-Bay, Ohio, was selected as the next place for holding the meeting; time, September, 10-12, 1901. Dr. J. C. Culbertson, of Cincinnati, Ohio, was selected as the chairman of the committee of arrangements. The meeting ended with a banquet at the Battery Park Hotel, given by the Buncombe County Medical Society.

Cincinnati Academy of Medicine.

Stated Meeting, September 24.

President Dr. Charles L. Bonifield, in the chair.

EPITHELIOMA OF WRIST.

Dr. Meyer L. Heidingsfeld presented a negress, aged 62, with a large epithelioma on the posterior surface of the right wrist, which had commenced about eight months before as a small wart, and now occupied an almost circular area about two inches in diameter. The growth was very warty in character, but did not extend deeply into the tissues of the wrist. The cubital glands were somewhat enlarged, but those of the axilla were not involved. In connection with this case he wished to present for Dr. Samuel E. Allen a similar case, in which the tumor had been excised by a so-called "cancer doctor"; on microscopical examination the excised portion was found to be not epitheliomatous but syphilitic.

DOUBLE HYDROSALPINX.

Dr. Edwin S. Ricketts presented specimens of double hydrosalpinx removed from a woman thirty-three years of age, whose husband was known to have had gonorrhea at the time of his marriage. She had never been pregnant. The unusual feature of the case was that she should have had hydrosalpinx and not pyosalpinx, and that on operation the ovaries and tubes were found absolutely free from adhesions.

PATHOLOGICAL SPECIMENS.

Dr. Henry W. Bettman presented some pathological specimens obtained during the previous week at autopsies at the Cincinnati Hospital.

1. *Cor bovinum*, in which the principal organic change was found to be a stenosis of the aortic valve, of so high a grade that only a medium-sized probe could be inserted into the opening. The cause of the stenosis was an enormous amount of granulation tissue completely surrounding and occluding the orifice. There was also incompetency of the aortic valve, as well as relative incompetency of the mitral. The heart was greatly enlarged, particularly on the left side. The cavities were all dilated. Myocardial changes of considerable degree also existed. The spleen enlarged and presented a large red infarct.

2. *Pseudo Female Hermaphroditism.*—The external and internal genital organs were presented. The individual had dressed as a woman, and as she had died from the effects of severe burns, inflicted in an attempt to save a number of helpless children, her womanly instincts were probably well developed. Her general build was rather masculine than feminine, though the breasts were of the feminine type. At the usual location of the clitoris there was a small undeveloped penis without urethra; the vaginal orifice was only about two inches in length and there was a separate orifice for the urethra. The testicles were situated to the right behind the nymphæ. There were no internal female organs of generation.

3. *Stone in the Kidney.*—Removed from a patient who died from alcoholic meningitis. The kidney with its capsule weighed two pounds. On opening the organ, a stone was found involving almost one-third of the entire mass, together with numerous smaller stones. The larger stones were surrounded by pus. The speaker was often in doubt whether the irritation of the stones caused the suppuration, or the pus formation resulted in a precipitation of the phosphatic material. The other kidney was normal beyond a compensatory hypertrophy.

INTESTINAL ANASTOMOSIS.

Dr. Magnus Tate called attention to Johnson's device as an aid to intestinal anastomosis—a cylinder of potato or other vegetable, which was crushed after the two ends of the intestine had been brought together by a Lembert suture.

DIABETES MELLITUS.

Dr. Mark A. Brown reported a case of diabetes mellitus, showing how, under strict diabetic diet, rest, and a single remedy, much could be done to alleviate the condition. The patient, when admitted to the hospital, complained principally of inability to retain urine and polyuria, which had persisted for more than a year. He was apparently in the best of health, robust, and looked ten to fifteen years younger than 71, his true age. Analysis showed a decided reaction for sugar. He was put on the bromid of gold and arsenic, ten drops three times a day, the dose to be gradually increased. Not only has the total quantity of urine passed in the twenty-four hours diminished, but the percentage of sugar in this decreased in amount, and consequently the total output of sugar has also lessened, showing beyond all doubt that improvement has taken place.

NEPHRITIS.

Dr. Alfred Friedlander presented a case of nephritis. The patient, a female, aged 28, had had scarlet fever in childhood, and remembered that at that time her face had become greatly swollen. For eighteen years following this she had enjoyed perfect health. Five years ago she became dull, stupid, with loss of appetite, dizziness, marked diminution in the secretion of urine, and finally convulsions. Similar attacks followed at irregular intervals, each attack being followed by apparent recovery with absolutely no abnormal symptoms during the intervals. A year ago she was married. During the pregnancy that soon ensued edema of the face and extremities, without ascites, appeared; albuminuria existed from the third month with casts. Her condition grew steadily worse, until, in the eighth month of pregnancy, it became necessary to induce labor. The patient promptly recovered. Three months later she had an attack of appendicitis, followed by dulness, marked disturbance of vision, intense headache, and almost complete suppression of urine. For four days thereafter, the urinary secretion did not exceed two ounces, but there was no edema of the face or extremities, no ascites, and no albuminuria. A week later, under treatment, the urine had risen to a pint and a half in twenty-four hours; at this time there was albuminuria and casts were found. Improvement was rapid, and at the present time she enjoys excellent health, the urinary conditions being normal.

INCIPIENT POTT'S DISEASE.

Dr. Albert Freiberg reported a case of incipient Pott's disease in which there was pronounced lateral, but no anteroposterior curvature. He called attention to the difficulty of early diagnosis in these cases, and said that even when some curvature was present, it was necessary to exclude stone in the kidney. The marked improvement of his patient in a well-fitting plaster jacket he also considered a diagnostic point of some value.

Philadelphia Academy of Surgery.

October 1, 1900.

President Dr. De Forrest Willard in the chair.

DISLOCATION OF THE TOE.

Dr. Gwilym G. Davis called attention to the frequency with which this injury was overlooked. The physical signs are slight separation of the toes on standing, local pain, projection of sole of the foot, and of the head of the metatarsal bone of the affected toe. The dislocation has such a tendency to recur that opening of the joint and loosening all fibrous attachments and tendons in narcosis is advised. A more sure operation would be to amputate. Resection he would not advise on account of the tendency of the toe to become displaced, and a source of pain and annoyance.

OPERATION IN THE PRE-PERFORATIVE STAGE IN TYPHOID FEVER.

Dr. Robert G. LeConte reported the case of a patient aged 23, who had been admitted to the Pennsylvania Hospital on account of symptoms pointing to appendicitis. He was anesthetized, the abdomen opened, and intestines drawn into the wound, when it was found that they were entirely covered in areas with plastic lymph, which was removed carefully. There were small dark spots along the ileum due to necrotic Peyer's patches. The peritoneal cavity was walled off as much as possible by gauze. Ten days later there was a discharge of feces through a fistulous opening, typical symptoms of typhoid fever developed and the blood gave a positive Widal reaction. He was discharged cured on the fiftieth day.

Dr. William J. Taylor believed that the only hope in cases of perforation during the course of typhoid fever was to operate at the earliest possible moment. In cases where there had been only a perforation without peritonitis and in which an operation had been done, recovery followed. The physician delays too long before referring such cases to the surgeon, and it devolves on the physician to make an early diagnosis.

Dr. G. G. Davis advised isolation of the diseased parts by means of gauze rather than invagination or suturing.

SHOT AS A NUCLEUS OF A [illegible] ULUS.

Dr. Robert G. LeConte reported [illegible] ich while hunting, had accidentally [illegible] is gun charge penetrated his left side. A few days later fourteen shot were discharged in the urine. Several years after the injury he complained of pain and tenesmus on micturition and other evidences of stone, which was found on examination. Litholapaxy was done, and in the fragments a No. 6 shot was found; it appeared to have acted as the nucleus. He made a good recovery.

Dr. William G. Porter reported a case in which a twig had acted as a nucleus of a vesical calculus.

PERFORATION OF THE SMALL INTESTINE.

Dr. William J. Taylor reported a case of a young man who, while hunting, accidentally discharged the gun, the stock of which struck him in the abdomen. A few days later general peritonitis developed. He was first seen by the speaker about the eighth day. Immediate operation was advised, and, on opening the abdomen, the intestines were found completely matted together by plastic lymph. While separating a portion of the bowel, a sudden gush of liquid feces escaped, which it was found had come from a perforation enclosed in the matted portion of the intestine. The perforation was closed with a double row of sutures, but the patient subsequently died.

Dr. Richard H. Harte desired to emphasize the importance of early operation in certain cases of contusions of the abdomen. In 4 cases of contusions in this region in which he had operated the intestine was found to be ruptured in 2 and the liver ruptured in the other two.

Dr. DeForrest Willard spoke of a case in which a child 3 years of age had fallen on a picket fence which had made a large rent in the stomach and had protruded through the diaphragm and upward toward the heart. The patient was operated on without an anesthetic, and the injury repaired, but death followed several hours later.

Dr. William G. Porter asked Dr. Harte what signs or symptoms he considered most important indications for opening the abdomen. Dr. Harte replied that shock, a slow pulse, tympanites and evidences of peritonitis were in his opinion most important.

Dr. Robert G. LeConte believed that if operation was to be done, it should be done within the first twenty-four hours, but after that point it should be treated upon the expectant plan.

PRESENTATION OF A SPECIMEN.

Dr. Michael O'Hara presented a specimen of intestine removed from a dog on which he had done an end-to-end anastomosis fourteen days previously. The union appeared to be perfect. In using his forceps in these cases he had not met with any hemorrhage from the mucous coat. In suturing, he endeavored to go through this coat. Dr. LeConte and Dr. Girvin both corroborated the statements of Dr. O'Hara that there is usually no hemorrhage.

AMERICAN.

1. **Internal Secretion of the Ovaries.**—Johnstone combats the rather prevalent idea of there being an internal secretion of importance to the economy from the ovaries and holds that there is no proof that the organism has any other function than the reproductive one. He attributes the troubles of the menopause and menstruation largely to defects of oxidization and excretion and not to any defect of secretion in the ovary. While he believes in reasonable conservative surgery he condemns those dangerous experiments which result in the leaving of a scrap of one ovary, tubes, etc., and the transplantation of the same.

2. **Internal Antisepsis.**—The questions raised by Wilcox are: 1. Is internal antisepsis possible? To which he answers in the affirmative, supporting it by the results of treatment in enteric fever, the examination of the sputum in tuberculosis and the examination of the urine. 2. Can it be detrimental? To this he also says, yes. Instances of fatal poisoning have occurred. 3. Under what conditions may it be employed? In response to this he insists on the importance of knowing all the conditions and avoiding useless attempts when the fact of structural degeneracy have been established. 4. How is it best obtained? Under this head he reviews the antiseptics employed, such as chlorin, silver, bismuth and hexamethylentetramin which have their special actions. Internal antisepsis he says is possible, may be useless or detrimental under certain conditions or may be absolutely contraindicated because of the patient. How best to attain internal antisepsis is a question to which the answer will vary with each successive year as our knowledge of infectious diseases and the best means of combating them is enlarged.

3. **Home Treatment of Phthisis.**—The importance of pure air and nutritive food are the chief points made by Eichberg, though he mentions others, such as moral treatment and drugs. He especially commends the practice of sleeping in the open air as much as possible as advised by Dr. Millett, of Brockton, Mass., in his recent article.

6. **Eye Strain.**—Ranney insists on the importance of proper attention to errors of refraction, the proper fitting, and the centering of glasses, attention to muscular tests, etc.

8. **Suprarenal Capsule in Heart Disease.**—From an experience of eight months Floersheim has found that suprarenal capsule produces a rapid effect on the heart, often toning it up remarkably and especially benefiting it in cases of dilatation, diminishing the area of the heart dulness and localizing the apex beat. It modifies the murmurs, making them more readily diagnosable and rendering the pulsation more rhythmic. Four cases are reported in which the drug was given. He has employed it in 5 gr. capsules, to be chewed by the patient.

9. **Combined Electrization.**—Rockwell finds the combined method of using the galvanic and the faradaic current together as especially beneficial in many disorders. Its musculo-sedative effect is more marked than that of other electric methods, and, therefore, it is valuable in local spasms. He has also found it beneficial as a stimulant over other methods of electric application in diaphragmatic paralysis and to more rapidly ameliorate the symptoms of Graves' disease.

13. **Obscure Abdominal Tumors.**—The class of tumors here described by Richardson are those of sudden appearance and often mistaken for entirely different conditions from those which they really represent. One of the commonest ones is due to a full bladder, and catheterization is therefore advisable for the diagnosis in a very large proportion of these cases. This should constantly appear in the mind of the surgeon and it should be the invariable rule in pelvic surgery to catheterize just before operation, especially in women. The second variety of rapidly-forming tumors may be idiopathic dilatation of the colon or so-called phantom tumor. It is less properly a suddenly appearing than a suddenly disappearing type. There is the condition in which the colon may be twisted and obstructed and show a well-marked tumor. Cases are here reported as illustrating this possibility, which of course, is a serious one. Another condition is peritonitis. Still other causes are dilated stomach, which can not always be correctly diagnosed, and the ovarian tumor with twisted pedicle is a possibility; the different points between it and hematocele are here discussed. Ectopic pregnancy, of course, is to be considered. Still other remotely possible sources are distended gall-bladder and intermittent hydronephrosis. It would appear from the whole of these facts that a positive diagnosis is not always possible. In most of these cases pain is the most important symptom and this alone demands careful examination of the pelvic viscera. The mistake of opening a full bladder is inexcusable. The diagnosis of distended stomach may be impossible. A large bulging tumor of the dilated colon gives signs which Richardson thinks will suggest the true lesion; if it subsides under anesthesia, has a typical resistence, tenderness; if it is rounded and symmetrical; if the obstruction is acute and there has been no gradual cachexia, the dilated colon is strongly indicated. The suddenness of appearance rules out the dilated coils of a chronic obstruction, such as, for example, that due to cancerous stricture. The diagnosis of extrauterine pregnancy is usually easy and of the ovarian tumor with twisted pedicle is easy when such tumor is known to exist, where one has not been previously found it is very difficult. In spite of the difficulty of diagnosis the signs point toward surgical intervention. It is of very little matter whether the case is one of ectopic pregnancy, or twisted pedicle, or extrauterine hemorrhage, or intestinal obstruction; in all the operation may be of use. It is, however, of some importance if expecting a serious lesion, he finds a full bladder or normal pregnancy. In all suddenly appearing tumors, however obscure they may be, intervention is demanded if the symptoms are the least urgent.

15. **Serum Therapy in Pneumonia.**—The possibility of serum therapy in pneumonia is here noted by Smith, who reviews the facts and sums up that "as the question stands today it may be stated that, experimentally, animals may be rendered immune, that their serum has protective property, and that continued investigation is doing away with some of the difficulties which previously harassed the early investigators. But the fact still remains that in dealing with the pneumococcus we are dealing with an organism capable of many variations and degrees of virulence, and that the sera obtained under such conditions must of necessity vary both in strength and character. Washbourne's method of cultivation seems to be a distinct advance, inasmuch as he maintains life and virulence in the culture over a longer period than have other observers. His investigations are recent, and it is too early to state what the result will be. Experimentally, antipneumococcus serum seems to be of value. Practically, that it is of any great value does not at present seem to have been demonstrated, as the reported number of cases are too few; the series of any one observer too small. What the future of the serum therapy in pneumonia will be it is too early to say."

18. **Obstruction of the Common Bile-Ducts.**—Deaver describes the symptoms and conditions of obstruction of the common bile-ducts. His methods of surgical treatment and technique of operation are also briefly mentioned.

19. **Gall-Stones and Appendicitis.**—Ochsner analyzes his cases in which appendicitis and gall-stones were present. During four months beginning February 1, 1900, he operated on eighteen patients suffering from gall-stones, of these six, or one-third of the number, suffered from appendicitis at the same time. He notices the principal relations between these two conditions and emphasizes the importance of examining the appendix when operating for gall-stones. The larger part of his paper is given up to reports of cases.

20. **Etiology of Gall-Stones.**—Shattuck sums up the conclusions that seem to him justified in regard to the origin of gall-stones as follows: 1. A sterile foreign body does not lead to gall-stone formation, though a sterilized gall-stone may be penetrated by, at least, the colon bacillus. 2. The contents of the hepatic and cystic ducts, and also of the gall-bladder, are usually sterile. 3. The common duct not infrequently contains bacteria, a fact readily explicable by the relation of the duct to the intestines. 4. Gall-stones have been produced experimentally by a number of observers, with a number of organisms. Mignot failed with virulent cultures, while he succeeded with attenuated cultures, alone, or in connection with a foreign body. 5. The presence of bacteria has been demonstrated in connection with a considerable proportion of cases of gall-stones. 6. The clumping of the typhoid bacillus led Dr. M. W. Richardson to think this peculiarity might play an important rôle, and he produced gall-stones in a rabbit by the introduction of a small amount of a clumped bouillon-culture into the gall-bladder. 7. The colon bacillus and the typhoid bacillus are the most common bacterial agents in gall-stone formation. He infers from this that stasis of the bile is a very important factor in their production.

23. **Diagnosis of Medical and Surgical Diseases of the Liver and Biliary-Passages.**—In this article Musser reviews the condition and symptoms and points out some of the differentiating factors, the specially puzzling conditions of stenosis and obstruction of the gall-ducts and the various symptoms of cholelithiasis. He calls attention to the facts that gall-stones may occur at an earlier age than usually believed, and that pain may be the only symptom and it may be variously located. While jaundice may never be present, in other cases, rigor and fever may be marked and pain insignificant. Persistent localized tenderness of the gall-bladder region often elicited only on deep palpation when the patient takes a full breath is of great importance. The diagnosis of disorders of biliary passages from subdiaphragmatic abscess, appendicitis, intestinal obstruction and acute pancreatitis are particularly noticed.

24. **Lesions of the Pancreas Simulating Gall-Stones.**—Richardson's article is a lengthy one, with the report of a number of cases. He points out the conditions of the pancreas which may lead to a mistake in the diagnosis of gall-stones, and also the possibility of making a serious diagnosis of malignant pancreatitis when such does not exist. The methods of operation for diagnosis of these cases are described, but it is not practicable to reproduce them here.

26. **Medullary Narcosis in Labor.**—Marx reports in detail twenty-three cases in which he has employed the subarachnoid method of producing anesthesia in labor. He gives the usual directions as to technique and mentions the possible dangers of collapse and sepsis. He has never noticed any untoward symptoms. His average dose is about one-quarter of a grain, the smallest, one-sixth. The symptoms which follow the injections he thinks are not due to cocain, as they follow saline solution injections. Asepsis, of course, is absolutely essential and he insists on quiet during the operation, as apprehension is always present, and psychic pain, if not

physical, may be produced. The patient is constantly being reassured by the surgeon and others are requested to refrain from talking.

27. **Subclavian Deligation.**—Graves' method is to substitute the cord of the brachial plexus of the nerves for the deeplying scalenus anticus muscle as a guide in ligation of the subclavian artery. He thinks by using this the brachial cord is exposed more easily, and by passing the finger behind it less time will be consumed and fewer important structures endangered.

29. **Appendicitis Larvata.**—This term, introduced by Ewald, indicates appendicitis of a chronic, insidious character, which does not necessarily develop into a really acute attack. The patients complain of intermittent pain, disappearing after a long or shorter period, and are often first treated for intestinal colic, gastritis, etc., and with careful examination pain may be elicited by palpation, sometimes at McBurney's point, sometimes in the neighborhood of the navel, or often in other regions, and occasionally there is slight elevation of temperature. The danger is that it may be followed at any time by an acute attack threatening life. Thienhaus reports three cases which illustrate the possibility of diagnosing this condition. Concerning treatment, he says it must be recognized that only operative measures must be taken into consideration. They are indicated because there is no other means of correcting the existing pathological conditions, and the patient is in constant danger of an attack of appendicitis followed by peritonitis. Barnsby says that when the tip of the appendix is adherent to some abdominal organ with or without vascularization of its peritoneal serosa, there is absolute indication for operations. Furthermore, in young female patients one has to deal with the possibility of a subsequent pregnancy, and, as we all know that appendicitis in combination with pregnancy gives the most serious prognosis both for the fetus (abortion is practically inevitable), and for the mother, it is the physician's duty to explain to the patient the above-mentioned complication and to resort to radical treatment, that is, operation.

30. **Tuberculosis of the Skin.**—Ravogli reviews the different forms of tubercular manifestations of the skin, classifying them as those due directly to the tubercle bacillus, of which lupus and its varieties are a type, and those due to toxins, which he calls non-bacillary eruptions, and certain other eruptions, which have been called by Johnson paratuberculoses. He is inclined to include in this latter class scrofuloderma, lupus erythematosus, and certain kinds of eczema described by Unna and Bazin.

31. **Pathology of Skin Tuberculosis.**—Heidingsfeld reviews the pathologic conditions found in lupus—circumscriptus, diffusus, erythematosus, verrucosus, crustosus, phagedenicus and resolutivus.

32. **Treatment of Skin Tuberculosis.**—Internal medication is of little avail in tuberculosis of the skin, and the external treatment is, therefore, the only rational one. The use of caustics is less general than formerly; solid silver nitrate is most in favor. Others which have been recommended are salicylic acid plasters, arsenical paste, chlorid of zinc, pyrogallic acid, etc. The galvano-cautery in the form of punctures is sometimes satisfactory in small nodules, in the cicatrix and in mucous membranes. Excision is effective if the disease is small and circumscribed, though sometimes it may return even then. Thorough scraping of tuberculous areas with a sharp spoon or curette has had exceptionally good results. It is not, however, available where the nodules are deeply imbedded. Caustic potash may be applied later and the dental burr is sometimes used in destroying discrete tubercles. The other method mentioned is linear scarification, consisting of parallel incisions in the diseased parts, going down until resistance is met. Cross-incision is also made and the process is repeated from time to time until new growths are destroyed and cicatrization takes place. The objections to this treatment are its necessarily long duration and the difficulty of getting patients to submit to it.

33. **The Cell Doctrine.**—Fisch combats the idea of the importance of the cell to a certain extent, claiming that the cells do not form the organism, but that the organism forms the cell. He brings to support his view the facts of certain unicellular organisms of high development in the marine growths, the bridges between the cells which are found in the vegetable kingdoms and to some extent in animals. He maintains that the present cell doctrine we are advocating is encouraging a sort of dogmatism that should be deprecated.

40. **Renal Tuberculosis.**—From a careful study of cases personally observed, and others that have been collected in literature, of nephrotomy and nephrectomy for tubercular renal disease, Ramsay deduces the following conclusions: 1. That renal tuberculosis may be classed as a semi-malignant form of inflammation, and that for this reason surgical treatment of some sort is always indicated. 2. That this surgical treatment will have a palliative or a curative end in view depending on the condition of the patient and the duration and extent of the disease. 3. That nephrotomy in renal tuberculosis is to be classed as a palliative operation, and that as a palliative operation for the immediate relief of dangerous symptoms, and as not precluding a later nephrectomy, nephrotomy with drainage of the abscess cavity is most valuable. 4. That resection of the diseased part of the kidney is contraindicated in renal tuberculosis because of the danger of leaving a tubercular focus in the portion left in the body. 5. That nephrectomy or nephro-ureterectomy is indicated in every suitable case, and in suitable cases should be followed by a lasting cure in 55.5 per cent. of the cases. 6. That the indications against nephrectomy are tubercular or other disease of the second kidney, or tubercular foci in other organs. 7. That tuberculosis of the bladder is not to be considered a contraindication to nephrectomy, as it will probably heal later. 8. That a small tubercular focus in the lung, if the patient otherwise is in good condition, may sometimes not be considered a contraindication. 9. That in doubtful cases, when it is questionable whether the patient can stand an immediate nephrectomy, it is better to do a nephrotomy, following it later by nephrectomy. 10. That the clamp method of controlling the pedicle is contraindicated from the danger of hemorrhage after removing the clamp. 11. That it is the safest to remove the ureter with the kidney, as a persistent fistula may give trouble if it be allowed to remain in the body. 12. That a certain proportion of these fistulæ will finally disappear, either after the removal of a deep suture or because of the slow disappearance of the tubercular disease in the ureter, which in these cases gradually changes into a fibroid cord. 13. That we may expect a steadily increasing number of final cures as our means of diagnosis improve and as our surgical technique is carried out more carefully and scientifically.

42. **Mesenteric Cysts.**—Dowd reports a case of multolocular cystadenoma in transverse mesocolon containing pseudomucin, and discusses the whole subject of mesenteric cysts. His summary is given as follows: 1. The occurrence in the transverse mesocolon of a multilocular cystadenoma which contained pseudomucin, and which was exactly like a cystadenoma of the ovary, suggests its probable origin as an embryonic ovarian sequestration. 2. The occurrence of dermoid cysts in a similar position suggests a similar origin. 3. The occurrence of chylous cysts in the mesentery, which have the structure and appearance of ovarian and parovarian cysts, and which have in their walls lymph-vessels, suggest embryonic cysts into which there has been an effusion of chyle. 4. The sanguineous cysts appear to be preformed cysts into which hemorrhage has taken place; hematomata in the mesentery should not be described as cysts. 5. The presence of cysts which have the structure of the intestinal wall suggest sequestration from the intestine. 6. Serous cysts are apparently similar in origin and structure to the cysts already considered. They are usually not situated in the path of the lacteal vessels. 7. Hydatid cysts form a class by themselves and are due to the tenia echinococcus. 8. Reports indicate that mesenteric cysts are being removed at least as often as once a month. 9. It is probable that all mesenteric cysts may be included in the

classifications: 1, embryonic cysts; 2, hydatid cysts; 3, cystic malignant disease.

43.—See abstract in The Journal of August 8, p. 449.

44. **Prostatectomy.**—Mynter reports a case of prostatectomy in which he was able to do the whole operation through the perineum by extending the posterior end of the longitudinal incision from the bulbus urethræ to the anus, in a curve around the anterior half of the anus on both sides, when he dissected loose the curved flap containing the anterior wall of the rectum and exposed the prostate to sight. With a grooved stone-sound he made a median incision in the prostate posteriorly without opening the urethra, introduced the finger, entered capsule and enucleated with ease both hypertrophied lateral and middle lobes, meanwhile pushing the prostate down in the perineum with the hand above the symphysis pubis. Unfortunately, the posterior urethra was torn at one place by the finger against the sound and therefore he drained the bladder for seven days. He thinks, however, this accident can be avoided in other cases and that the operation thus performed will be an ideal one.

57. **Pelvic Inflammation.**—After first describing the condition, its symptoms and diagnosis, Ill passes to the treatment, which he thinks has been heretofore too exclusively surgical. In acute cases the cause should be considered, though it does not materially change the treatment, excepting in tuberculous cases. The patient should be kept in bed, bowels moved by salines every second day, diet be unexciting, pain controlled by ice-bags for a short time, hot vaginal douches with permanganate of potash solution (1 to 20000), small blisters over the seat of pain, and in some cases tamponing the vagina with iodoform gauze and applying cantharidal collodion on cotton to cervix if there is great sensitiveness to touch and swelling; the latter produces a very copious purulent discharge and should be removed in four hours and followed by douching several times a day. Then comes the use of a 10 per cent. solution of ichthyol in glycerin, applied in the evening and followed by a large vaginal douche before removing the tampon in the morning. The blisters may be resumed in five to eight days. For rectal tenesmus and discharges of mucus an opium suppository may be given; an opiate is in any case best administered by the rectum. Relapses are common from sexual excitement, cold, menstruation, etc. All these causes can be controlled excepting the menstrual period, and the author has been making a trial of the treatment suggested by Grammatikati for the control of this function and will report the results in the future. The treatment of the chronic form consists in an endeavor to produce absorption of exudate and adhesions and replacing of the displaced organs. He would paint the vaginal roof with tincture of iodin and apply a glycerin-ichythol tampon, and if the patient is found to tolerate it, add to the tampons until the vagina is firmly packed. They should be retained for forty-eight hours and withdrawn by a string. Two days following the removal the patient should be directed to take a large hot vaginal douche night and morning, preferably in the knee-elbow posture. In these cases he has also found much good from the Brandt method of massage. Pelvic cellulitis is also described and the treatment mentioned. It consists in the use of large hot permanganate of potash or lysol douches or weak mercuric bichlorid. The use of the ice-bag over the affected side, and in less acute cases, after the abrasion or fissure of the cervix is looked for, carefully cleansed and kept clean; thorough swabbing with hydrogen dioxid, followed by an injection of a 5 to 10 per cent. mixture of iodin in glycerin is usually sufficient. In tubercular inflammation, of course, the case is a surgical one from the beginning.

60. **Ureterointestinal Anastomosis.**—Peterson sees no special value in intestinal implantation of the severed ureters. In very few instances do the experimental animals overcome the infection and survive. Maydl's operation, which he prefers to call uretero-trigono-intestinal anastomosis, is favorably spoken of, and he thinks this method as modified by himself has been a perfectly justifiable surgical procedure in vesical extrophy. Uretero-intestinal anastomosis by the formation of permanent fistulæ connecting the bladder and rectum is also spoken of as somewhat promising, though he doubts whether it can ever be successfully made in cases of purulent cystitis due to enlarged prostate.

56.—See abstract in The Journal of September 13, ¶120, p. 976.

63.—Ibid.

65. **Hemorrhage After the Menopause.**—The causes of hemorrhage after the menopause are given by Davis as follows: 1. Granular endometritis, which can usually be relieved by aseptic curetting. 2. Atheroma of uterine blood-vessels, which offers but little prospect of relief, though changes in the diet consisting of an abundance of well-cooked meats and fruit might prove of benefit with tonics and alteratives. 3. Vasomotor relaxation is a possible source of hemorrhage, improvement of general health by the use of tonics, with special attention to the nervous system will cure this disturbance. 4. Uterine polypus should be readily recognized and promptly removed. 5. Uterine myofibroma covers too extensive a subject to be fully treated here. 6. The last cause, malignant disease, is the most important. He thinks that it rarely attacks the nulliparous uterus and generally involves some sore or old laceration, especially of the cervix. Such injuries, therefore, should be attended to promptly. He does not credit the employment of methods to prevent conception with having much to do with the existence of cancer. The earlier the operation is done, the better the chance; it is important to investigate early all cases of hemorrhage after the menopause, especially if there is any suspicion of malignant disease.

69. **The Prophylactic Douche.**—After noticing the change of views of recent years in regard to the use of this method and discussing the literature, Chapman says that he has been in the habit of using the preliminary prophylactic douche, but has been led by his studies to question the advisability of so doing unless there is some suspicion of gonococci. He is almost persuaded that the bacteria will meet with more timely neutralization without the primary douche than with it. After the completion of labor in the ordinary case, the douche is used until the third day, unless there is some indication for the same on account of offensive discharges. His success with the method has been very satisfactory.

76. **Cocain as a General Anesthetic.**—Murphy reviews the history of anesthesia by subarachnoid injections of cocain, giving credit to Corning for its origination, gives full directions as to the technique, and reports nine cases in which he has successfully employed the method. He has seen no serious accidents follow the anesthesia thus produced, though vomiting and headache may appear during the operation or some hours later and last some little time. He has also noticed some perspiration and pupillary dilatation, with temperature and rapid pulse, but they all disappeared within twenty-four hours. The important points are the thorough asepsis, use of aseptic material and the assurance that the needle has entered the spinal canal by seeing the cerebrospinal fluid flow clear before introducing the cocain.

82.—See abstract, vol. xxxv, p. 764.

83.—Ibid., p. 763.

84. Ibid., p. 764.

85. **Diabetic Coma.**—Ely argues in favor of the rather widely accepted theory that diabetic coma is an expression of an acid intoxication due to the presence in the body of B-oxybutyric acid in large quantities, and while he admits that the result of alkaline treatment has not been very satisfactory in the past, he reports several cases coming under his observation in which they have been very favorable. He is impressed by the difficulty which attends the administration of alkali, especially the risk of favoring intestinal putrefaction, and insists on the importance of careful scrutiny of the condition of the bowels and digestion in these cases. He would warn against the too-rapid withdrawal of carbohydrates in patients suffering from diabetes, as this may favor the development of coma from the readiness of proteid food to yield acid in its decomposition.

The alkali treatment should be instituted prior to the reduction of carbohydrates and they should be carefully withdrawn.

87. **Koplik's Spots.**—From a study of 140 cases of measles, Maroney thinks they prove conclusively that the presence of Koplik's spots is an absolute pathognomonic sign of measles, from which a positive diagnosis can be made at an early stage of the disease. They appear in the great majority of cases before the appearance of any skin eruption and in almost one-half the cases before any coryza or conjunctivitis, and their recognition affords an early means of isolation and offers a means of limiting if not aborting epidemics in hospitals and institutions.

90. **Tattoo Marks.**—Ohmann-Dumesnil describes his method of removing tattoo marks, which is an application of a bland solution of the vegetable ferment caroid especially prepared for use as a physiologic solvent, which is poured over and rubbed into the tattooed surfaces and then the spot is covered with two or three layers of gauze soaked in the solvent. In a few days, when the latter are removed, the tattoo marks appear light and hazy. Very shortly afterward some crusts appear and when they fall off all trace of the tatoo is gone.

97. **The Specific Gravity of the Blood.**—Busch, Kerr and Filsinger, the authors, give the results of their experiments to test the specific gravity of the blood and tabulate some eighty-eight cases in regard to the value of the blood-count, hemoglobin, etc., in connection with the specific gravity. They summarize their conclusions as follows: 1. In most cases the specific gravity and the percentage of hemoglobin of the blood present such a close relationship to one another that the latter may be predicated from the former with sufficient accuracy for clinical purposes. 2. Both v. Fleischl's and Gower's instruments are liable to an error of 10 per cent. or more. 3. There is liable to be very slight, if any, error in the determination of the specific gravity by Hammerschlag's method.

101.—See abstract, p. 763.

104.—See abstract in The Journal of July 14, p. 117.

105.—Ibid.

106.—Ibid.

107. **Suprapubic vs. Vaginal Section.**—Benjamin insists on the greater advantage of performing abdominal section over the infrapubic operation and quotes a number of authorities in support of his view. The chief advantage is the ability to make a more thorough operation, to discover complicating conditions and to meet the complications. He offers in conclusion the following as his suggestions in regard to the matter: 1. The abdominal operator has the advantage of sight, touch and access to the disease. 2. He is able to explore the whole abdomen for visceral disease. 3. He can do careful, complete and conservative work. 4. There are few diseases of the female pelvis, except certain abscesses, operable from below that are not best treated from above. 5. Surgery of the female pelvis should be the practising of good surgical sense and not fads.

113. **Tuberculosis.**—The usual facts in regard to precautions and prophylaxis are reviewed and the author gives his own treatment somewhat detailed. He thinks the ordinary cases, with no throat complications, are benefited by altitude, but every case should be studied by itself in this regard. Advanced cases should never be sent away from home. Cases with catarrhal complications do best with a climate of a lower elevation. He has had no experience with the pneumatic cabinet, but takes the opinion of others that it is a valuable adjunct. The cool morning bath is often of advantage, and he would shut off the use of tobacco from tuberculous subjects. The diet should be nutritious and digestible. The teeth should be carefully looked after. For tonics he suggests cod-liver oil, arsenic and iron, which last he prefers in the form of ferratin; the creosote derivatives in combination with strychnin sulphate are the drugs with which he has had the best results. He prescribes the following formula:

℞. Strychnin sulph........................gr. ss.
Guaiacol carbonate..........................ʒii

M. Ft. caps. No. xxiv. Sig. One twenty minutes after meals.

He also uses the inhalation of a 40 per cent. aqueous solution of formic aldehyde, using 20 to 40 drops on a piece of cloth twice daily. For night-sweats he finds camphoric acid of advantage when atropin and other drugs failed. For cough he gives codein sulphate in combination with chloroform and wild cherry. For vomiting, cocain and menthol. For intercostal neuralgia, hot-water compresses, counter-irritants, etc. For hemoptysis hydrastis canadensis, morphin, ice, etc. For fever, lactophenin, phenacetin and acetanilid. Nux vomica, cinchona, etc., are often useful. In advanced cases there is little to be done. He believes the disease is curable under certain conditions. If we can encourage the patient to hope for recovery we have done much.

114. **Prophylaxis of Shock.**—Shock consists of central nerve depression due to too severe or too long continued stimulation showing itself in the symptoms referable to three causes: 1. Vasomotor paralysis. 2. Respiratory paralysis. 3. Cardiac paralysis. The distinction between collapse and shock insisted on by Crile is noticed. To prevent shock in severe surgical operations, the first thing is to give the patient rest and the patient should be insured ample sleep for a few days preceding, and the preliminary purgation be completed twenty-four hours prior to the operation. Cardiac stimulation can be used to advantage in patients suffering from functional or organic disease of the heart. All respiratory troubles should be relieved as much as possible and lowered vascular tone be improved by constitutional remedies. Morphin injected is a help in many cases and may be used in ¼ gr. doses twenty minutes before giving the anesthetic in combination with atropin and strychnin. Threatened respiratory failure can often be avoided by stopping the anesthetic and inverting the patient. Ammonia is an efficient stimulant and acts immediately. Inhalations of amyl nitrite are of value when sudden collapse threatens, though contraindicated in profound shock. Saline infusion is the most satisfactory method of avoiding shock and is an efficient prophylactic. Speed is of importance in operation.

115. **Acute Tympanic Abscess.**—Landfried reports a case with the absence of the ordinary acute tympanic signs of suppurative mastoiditis following abscess of the middle ear from which he deduces that we had better depend on the presence of the continuous flow of pus through the perforated drum in determining the possibility of mastoid complications rather than on the intensity of the acute objective signs ordinarily seen with such complications. He also points out the danger of delay in operating on mastoid cases occurring late in the history of otitis media where suppuration has been continuous, and the need of proper equipment of the doctor who has to treat such cases. His own conclusion was to err, if to err is necessary, always on the side of incising the drum. A large incision made early is one of the most conservative things he knows of in surgical practice. It is not safe to chisel only into the mastoid antrum. The complete carving of the mastoid processes, even if the sinus should be exposed, had better be done. The case also illustrates the value of the aseptic aspirating needle in determining whether or not it is imperative to open and flush the lateral sinus or to ligate the jugular vein. Where there is no thrombosis the blood will flow through the needle passed into the sinus. Prognosis in any case of running ear is uncertain as regards complications until the discharge has completely ceased.

122. **Epigea.**—Aaron suggests epigea as a remedy for gastric eructations. Although the plant has not been recognized officially, it has received some attention. Three glucosids have been isolated, namely, arbutin, ericolin and urson, besides other substances. He has had some very happy results from its use, but is not able to say to which one of these principles the therapeutic value is due. The plant is well known, being the common trailing arbutus.

FOREIGN.

The Lancet, September 22 and 29.

The Etiology of Rheumatic Fever. Frederick J. Poynton and Alexander Paine.—The authors first review the history of the microbic theory of rheumatic fever, showing how complicated and uncertain the present state of the bacterial theory of rheumatic fever still remains. They recognize five different views as held: 1. Allowing that the disease is microbic it is held that there is no specific micro-organism, but that it is a form of septicemia due to staphylococcic and streptococcic infection. This they do not find supported sufficiently to be probable, considering the absence of suppuration. The second view is that rheumatism is due to a specific diplococcus; the third, that its cause is a specific bacillus. The fourth raises the question of mixed infection of bacilli and cocci as in diphtheria, but the authors consider this is unsatisfactory. The last view holds that rheumatic fever is not a disease *sui generis*, but a particular reaction of tissues to other infections. To summarize their own view they think it more probable that the micro-organism is always present in rheumatic fever, that it is capable of isolation, and that it may produce similar symptoms in suitable animals, and that it will probably exhibit some definite peculiarities on culture. They also think that it would be a simple and not a mixed infection. Their investigations are given in detail and the diplococci which they found, described, with the experiments on rabbits, in which the symptoms of the disorder were reproduced. The authors are not as yet in a position to state thoroughly all the morphologic characteristics of these micro-organisms, but they ascertained the following details: I. They are minute cocci associated in pairs varying in size but averaging .5 of a micron in diameter. 2. In liquid media they grow in chains. In solid media they grow in masses that resemble the staphylococci. 3. They are both anaerobic and aerobic. The authors find the best culture-medium to be milk and bouillon slightly acidified with lactic acid, and the organisms grow rather better in the anaerobic than the aerobic tubes. They believe that there is little doubt of their identity with those discovered by Triboulet in 1897 and Wassermann in 1899. They can not say that it is the sole cause of rheumatic fever in view of the statements of Achalme, Thiroloix and others. There is a strong clinical likeness between rheumatic fever and the disease produced by this diplococcus in rabbits. The diplococci are found in the tonsils, in the cardiac valves, pericardium, and in the nodules of fatal cases of rheumatic fever, and Poynton and Paine have also isolated them from the joint exudation, heart blood and kidneys of rabbits as well as from the liver and lungs. The demonstration of these organisms in man is not easy. This they lay to the fact that rheumatic fever is essentially a disease in which there is great resistance; even in fatal cases the reparative processes are often well defined at the site of some of the local lesions and the tissues in which they are found are more difficult in structure to investigate. In concluding their paper they remark that the term "infective endocarditis," which has been for some time under suspicion, can not be used longer in contradistinction to "rheumatic endocarditis" for both are plainly infective. They believe that their investigation has made the relation of malignant endocarditis, as they prefer to call it, to rheumatism much clearer. In simple rheumatism the diplococci are not found at first on the surface of the valves, and the disease tending as it does to recovery, they are destroyed by phagocytosis and possibly in other ways, the valve undergoing sclerosis. In the malignant type they reach the free surface and multiply with great rapidity and if they are detached by force of the blood-stream they may possibly give rise to a condition of rheumatic septicemia recognized clinically as malignant endocarditis.

British Medical Journal, *September 29.*

A Discussion on Influenza as It Affects the Nervous System.—The discussion was opened with a paper by Dr. Judson S. Bury, who called attention to the nervous system in influenza, stating that we assume and have proof that in this condition the brain tissues are attacked by bacilli in the first group of cases he considered. The disease develops during and after the febrile stage, sometimes being the sole representative of the effects of the influenza poisoning; meningitis and hemorrhagic encephalitis are the best examples of this type. In the second group are placed nervous diseases which usually occur after the attack has subsided; neurasthenia and multiple neuritis are examples. Here it is assumed that the toxins produced by the bacilli are more dilute and less virulent than in the first group. The division is not strictly correct, but is convenient from a clinical standpoint. Of the nervous symptoms belonging to the first group he notices first the comatose type. An examination of the brain may reveal nothing abnormal, or there may be congestion and even purulent meningitis with or without an encephalitis. The meningitis may accompany encephalitis or may exist secondary to a purulent otitis. The delirious attack is another manifestation; in contrast to the drowsiness and unconsciousness there is restlessness, irritability and delirium, and even mania. Cases of both kinds were reported. Spinal paralyses have been also noticed, and in rare instances show themselves during the attack. They may constitute, as in the cerebral type, its salient features. Of the second group he notices and reports cases of local and more or less general paralysis involving the spinal cord and nerves, as well as neurasthenias occurring as sequelæ to influenza. The discussion on this paper was quite general and was participated in by Drs. Broadbent, Allbut, Eade and others. Dr. Allbutt agreed with Bury in thinking that the frontal cerebral lobes are preferentially attacked by influenza.

A Discussion on the Problems of Gastric Ulcer.—Payne opened the discussion by giving the statistics of St. Thomas' Hospital, and assuming that the first problem of gastric ulcer is whether it is increasing; he thinks it really no more prevalent than formerly. The second problem refers to diagnosis. He thinks that pain is not often characteristic or typical; in a number of cases it was not even mentioned, and in one fatal case it was positively stated that there was no pain whatever. Hematemesis, the only characteristic symptom, was definitely recorded in but seventeen out of forty-eight fatal cases. As to hyperacidity, which has been made much of lately by some German physicians, he has nothing to say at present, as he has not been willing to wash out the stomach in suspected gastric ulcer. The general conclusions seem to be that while hematemesis is accompanied by other gastric symptoms as the most trustworthy sign, it is not absolute and may be due to many other causes. As to whether we can draw a clear distinction between acute and gastric ulcer, he is inclined to answer in the negative. The etiology of gastric ulcer is discussed, and he holds that there is no evidence in favor of the bacterial origin. The theory that it is due to disturbed innervation seems hardly worth considering. The hypothesis of hyperacidity might account for the continuance of the ulcer, but not for its commencement. Payne therefore concludes that we have not at present a very plausible explanation of the origin of the lesion. The predisposing causes are also questioned by him. He does not find that it is so exclusively met with in the poor and the female sex, among servant girls, etc., as generally held. As regards its prognosis, the acute ulcer tends to recover, so that in the young the prognosis is relatively good, but in chronic ulcer it is not so favorable and the only difference between the acute and the chronic disease is in its duration. During treatment he prefers to have water taken by the mouth, as it is less likely to do harm than in the reverse course, and it certainly assists the patient to go longer with rectal feeding. In conclusion he asks if acetonuria is a frequent accompaniment of rectal feeding. In the discussion of Payne's paper Gordon believed that the microbic theory of the origin of gastric ulcer explains the facts better than any other.

The Origin of Gout. William Ringrose Gore.—The author combats the uric-acid theory of the cause of gout, though the blood always contains uric acid, but whether it increases in the acute attack is very doubtful. Its presence is only a symptom and would be produced by the action of the digestive toxins on the liver. His conclusions are that gout is not due to the presence of uric acid in the blood, but these symptoms are due to toxins and this toxin is formed by the action of one of the intestinal bacilli on the intestinal secretion specially altered by diet, and this alteration is assisted by hereditary predisposition.

Subcutaneous Saline Infusions in Pneumonia. William Ewart and Beaumont Percival.—Cases are reported bearing on the question of the value of saline subcutaneous infusions in pneumonia, especially in connection with the results published by Dr. Clement Penrose, of Baltimore. They classify cases as regards their prognosis into two groups: 1. Those likely to recover. 2. Those almost sure to be fatal. The first group does not lend itself to any profitable therapeutic investigation, but there is still a third class with uncertain and serious, though not hopeless, prognosis, which may test thoroughly the therapeutic methods. The cases here reported were all selected on account of their gravity, and injections in all were administered with strict antiseptic precautions. In one of the six recovery took place, the others died. Briefly stated, the practical conclusions are as follows: 1, in the severe cases treated no unfavorable results were observed from the saline infusions; 2, these seemed to delay rather than to accelerate the fatal termination; 3, they were not resented by the patients, and by some of them they were acknowledged to be comforting; 4, they were powerless to check the fatal course of the pneumonia in the worst type of cases; 5, they do not seem, except in Case 4, where no pus but clear serum exuded from the cut surface of the gray hepatisation, to have made any difference in the characteristic appearances of the pulmonary changes. At the same time, while the results have been disappointing, they do not suffice to prove that saline infusions are absolutely useless. A different combination, a larger bulk, or a greater frequency of administration might lead to very different results. The cases reported were exceptionally severe, and may have been incapable of recovery. "The effects noticed were, nevertheless, in our estimation, such as to recommend the method for a more extensive trial in cases with anxious prognosis; for among them cases may occur which are not of the worst type, and in which an installment of relief, such as that observed in some of the cases reported, might be sufficient to save life."

Consanguinity as a Factor in the Etiology of Tuberculosis. Charles A. Davies.—Davies discusses the subject of consanguinity in its relation to the etiology of tuberculosis, from the study of facts as shown in the Isle of Man. This is a small territory where intermarriage has taken place to a great extent, varying, however, in certain localities, which fact aids in this study. Its mortality from tuberculosis is very high, the annual mortality being 25.7 per 10,000; roughly speaking, this is about double the rate prevailing in England and Wales. The climatic conditions are eminently favorable to life. The sunshine is greater than in most parts of the British Islands. The winds are similar to those on the mainland and the combination of mountain and sea air seems to be conducive to health, and Davies thinks that the whole climate is eminently suitable for the treatment of lung disease. The soil is dry and fairly well drained and he has not come across a single case of malnutrition due to poverty. As a rule the natives are well nourished in body, and happy and contented in mind. The two chief occupations are agriculture and fishing, though many of the men follow the calling of mariners, and there is a little lead-mining. There is no excuse for the high amount of tuberculosis other than consanguinity; in one parish where the inhabitants have long been comparatively isolated from the other parts there is a notorious amount of consumption, and a remarkable freedom from it prevails in another region where the condition in this regard is the reverse. After a careful study of the whole question, he has come to conclude that the chief factor in the production of tuberculosis in the Isle of Man is consanguinity.

Archives Gen. de Medicine (Paris), August and September.

Importance of Arterial Pressure in Anesthesia. S. Duplay and L. Hallion.—Death in chloroform or ether anesthesia is due primarily to the reduction of the arterial pressure caused by the drug. The phenomena noted in the arterial pressure and the pulse are not such as are observed in asphyxia. Extensive experimental research on dogs has shown that the reduction of the arterial pressure to zero and complete suppression of the heart-beat are preceded, it is true, by a complete syncope of the respiration, but the drop in the arterial pressure has already commenced its downward course before the respiration is suspended. If this reduction has progressed beyond a certain point it is impossible to arrest and restore it, but within this limit it is possible by suspending the administration of the chloroform or ether and by artificial respiration to arrest the drop in the arterial pressure and bring it back to normal. The immediate factor of death, therefore, in chloroform or ether anesthesia is the diminished arterial pressure. Consequently, if we register and watch the condition of the arterial pressure during anesthesia, we will be kept informed as to the effects of the poison in the system and be able to graduate the necessary intoxication and keep it inside the danger limit. "Nothing is easier and more harmless than to administer chloroform to a dog indefinitely if a manometer is applied to an artery and the register watched for the slightest indication of danger." In one of the curves cited the amount of chloroform was graduated to keep the arterial pressure between 10 and 13 cm. mercury. No information derivable from the pulse, the respiration nor the corneal reflexes would have allowed such accurate regulation and such complete absence of danger. The harmless zone is easily established. Once past this zone the reduction in the blood-pressure irremediably continues its downward course. Other points mentioned in this article are that artificial respiration has probably a massaging effect on the intrathoracic vessels, and that direct digital massage of the heart might prove useful in raising the blood-pressure when restoration by all other means has failed.

Spontaneous Rupture of Gall-Bladder. S. Machard.—In the 39 cases of rupture of the gall-bladder on record, 22 were caused by lithiasis, 10 by typhoid infection, 3 by infectious icterus and 4 were of unknown origin. Machard describes a fatal case in which the dilatation and rupture of the organ was due to adhesive supra-umbilical peritonitis, associated with perivisceritis, liver and lung affections and interstitial nephritis. If diagnosed in time, cholecystostomy offers the best chances for intervention. In all cases of dilatation of the gall-bladder with peritonitis, spontaneous improvement should not be awaited, as perforation is liable to occur at any moment.

September

Typhoid Fever in the Course of Active Syphilis. G. Etienne.—In the writer's experience of 600 to 700 cases of typhoid fever, five extremely severe cases were observed to occur in patients with concomitant active syphilis. In another case multiple exostoses developed a few months after a typhoid fever in a syphilitic. The evidence seems to show that active syphilis aggravates the course of typhoid fever and is not attenuated by the latter, as some claim.

The Diabetograph. F. Coulhon.—A graduated glass tube with a stopcock at the lower quarter, below which the tube tapers to a point, is the simple apparatus with which it is possible to estimate the exact amount of sugar in the urine without any calculation. Experience is confirming its mathematical precision and rapid and easy manipulation. The tube is filled with urine to a certain point, and 2 c.c. of Fehling's solution are boiled in another vessel, diluted with five or six times its amount of water. The urine is added to the reagent by turning the stopcock at the bottom of the tube. When the reaction occurs in the solution the figure on the tube to which the urine has fallen indicates the amount of sugar in a liter of urine. The graduation on the tube is calculated according to the fact that when one volume of urine reduces an equal volume of Fehling's solution, there must be 5 gm. of sugar in a liter of the urine.

Echo Medical (Lille), September 6.

Antagonism Between Typhoid Fever and Syphilis. Mariau.—Among the points discussed at the International Medical Congress was the tendency of typhoid fever to attenuate a pre-existing or simultaneous syphilis. Ducrey stated that it extinguished the syphilitic infection and Julien reported the case of a patient with a typical primary indurated chancre who was taken with typhoid fever. The chancre rapidly healed and during the twenty-five years since he has never had any further manifestations of specific infection. Mariau, on the other hand, has observed a case in which severe primary syphilis was ameliorated to practical recovery by specific treatment. After a year of health the patient contracted typhoid fever with two relapses. *During his convalescence a new* specific eruption appeared on the trunk, indicating a revival of the syphilitic process. Mariau therefore warns that concomitant typhoid fever is no reason for neglecting specific treatment.

Gazette Hebdomadaire (Paris), August 19 and September 13.

Forcible Reduction of Hump in Pott's Disease. A. Broca.—Fifty-five out of the 83 cases of Pott's disease treated by Broca date from more than a year ago. Forcible reduction during horizontal traction was done in 46, with the immediate application of a plaster cast embracing the thighs and part of the head, during suspension in narcosis. Of the entire method of forcible reduction introduced by Calot, nothing has survived except the application of the cast in suspension. The hump has returned in every one of Broca's cases except in 10 fresh ones, in which the traction alone was sufficient to straighten the spine. *He considers two or three months of dorsal decubitus* indispensable, with at least a year of immobilization.

September 13.

Immunity of One Twin to Infection. Cuche.—One twin is apt to be weakly, to bear the entire burden of inherited infection, tuberculous, syphilitic, etc., while the other twin is exempt. Cuche states that this has occurred with such regularity in his experience *that he is inclined to suspect some* law regulating the phenomenon.

Semaine Medicale (Paris), September 28.

Physiologic Action of Mountain Climate. J. Jaquet.—The effect of altitude on the blood was tested in a series of experiments on rabbits. It was found that reduction of the atmospheric pressure equivalent to 100 mm. of mercury was sufficient alone, apart from any other factor of mountain climate, to change the composition of the blood in the same way as is observed after a trip to the mountains. The total amount of hemoglobin increased 20 per cent. Six rabbits, before the test, averaged 5,530,000 red corpuscles and 12.7 per cent. hemoglobin. The reds increased by the end of four weeks to 5,749,000, and the hemoglobin to 12.97 per cent. Six others under the same conditions in every respect, except that the air was rarefied to correspond with the atmospheric pressure at Davos, showed an increase of red corpuscles from 4,552,000 to 6,091,000, and of the hemoglobin from 11.54 to 14.40 per cent. The total amount of hemoglobin corresponding to one kilogram of the animal's weight was, at the close of the tests, 23.7 per cent. more than in the control animals. The dryness, cold and other features of high altitudes, tested separately, had no appreciable influence on the composition of the blood. Jaquet also experimented on himself and a companion. For four weeks all the food was analyzed and exactly the same quantity taken each day. The first seven days were spent at Basle, then thirteen at Chasseral, in the Jura mountains, at an elevation of 1600 meters, concluding with seven days after the return to Basle, omitting from the calculations the trips to and from the mountains. Each day the urine and feces were weighed and analyzed. The interesting results are tabulated in full. They demonstrate that the modification of the blood and the metabolism of nitrogen closely parallel each other. The increase in the red corpuscles and in the hemoglobin during the stay in the mountains was accompanied by a marked decrease in the nitrogen eliminated. After return to the lower altitude the reds and the hemoglobin gradually diminished, while the elimination of nitrogen increased in inverse proportion. The amount of nitrogen retained by the organism was much more than could have been required for the neoformation of the elements of the blood. *This suggests that the action of altitude* is not restricted solely to the blood-formation, but that it may induce a partial protoplasmic regeneration throughout the organism, conferring new vitality and resistance on other elements besides the blood. He states that this general modification of the tissues affects also the respiratory interchanges, as he will describe in a later communication.

Berliner Klinische Wochenschrift, September 27.

Etiology of Chronic Edema. H. Rosin.—A woman of 42 presented a typical case of progressive, simple, diffuse edema of the skin without participation of any organ in the morbid process. *Abnormal permeability of the vessels* is the probable cause, such as Senator accepts as the cause of hydrops-anasarca in renal affections. Magnus has artificially induced edema of the skin by hydremic plethora in experiments on animals with certain toxins.

Polyneuritis Consecutive to Malaria. C. A. Ewald and Baumstark.—Motor paralysis and atrophy of the muscles were observed in three cases consecutive to malaria contracted in Kameroon. One case developed a rapidly fatal Landry's paralysis. The central nervous system was found intact, confirming the assumption that certain kinds of paralysis are primarily due to an acute polyneuritis in the peripheral nerves. In another case the polyneuritis was accompanied by mental confusion.

Centralblatt f. Bakteriologie (Jena), August 22 and September 4.

The Mechanism of Infection. A. Radzievsky.—A fatal infection in animals is not due exclusively to the multiplication of microbes. Large numbers are destroyed by the juices of the organism, sometimes entirely outside the cells. The organism is not passive in infections, but takes an active part, producing substances to destroy the microbes. When they are killed and dissolved their toxins are liberated and to this is due the clinical aspect of the infection. The organism reacts the same to a fatal as to a non-fatal infection. The difference is merely the amount of the final intoxication. The increase in the virulence of microbes after passage through animals is due to the tendency of the juices to destroy them.

To Free a City from Mosquitoes. C. Fermi.—The organized efforts which resulted in freeing the city of Sassari from mosquitoes have already been described in The Journal, xxxiv, p. 1576. Fermi remarks that it is unnecessary to use more than 5 c.c. of petroleum to a square meter of surface in killing the larvæ in water, and that, as they require fifteen to twenty days to develop, *renewal of the oil is not necessary for* fourteen days. He mentions that Mionte, in Ionia, and Pergamo, in Asia, were abandoned by the inhabitants in ancient times on account of the numbers of mosquitoes.

Protection of Man Against Mosquitoes. C. Fermi.—There is very little prospect that any chemical means of warding off mosquitoes will prove effective. Out of the countless substances tested, only the fumes of chlorin and ammonia, and wood and tobacco smoke proved to have any effect.

Prophylaxis of Malaria. E. Di Mattei.—Four workmen, who had never had malaria, were brought from Catania to Valsavoia every evening at 5:30. They were hurried from the train, a few steps, to a large two-roomed building, where they spent the night, and were taken back to Catania for their day's work next morning at 7:30. The numerous windows and the door were all open, but closely screened. The inside walls were white, to detect any mosquito that might force an entrance when the door was opened to admit the men and then closed until the next morning. Di Mattei accompanied them every night. The experiment lasted thirty-three days and none of the party showed the least trace of malarial infection at any time. No quinin nor medicines of any kind were administered. Valsavoia is one of the most notoriously malarial spots in Sicily.

Cntralblatt f. Kr. der Harn u. Sexual-Organ (Leipsic), September 15.

Primary Carcinoma of the Urethra. Hottinger and Oberlaender.—The first symptom of the lesion was a discharge from the urethra in the four cases reported. They raise the total number of cases of carcinoma of the urethra to twenty. The benefit of operation is evident. The two operated on are in good health now, 3 and 4½ years later. In one case the carcinoma occurred in a diabetic.

Deutsche Medicinische Wochenschrift (Leipsic), September 20.

Morphology of Bacteria an Indication of Their Virulence. H. Marx.—The small, spherical, metachromatic bodies first observed in the bodies of bacteria by Babes and Ernst are not found in all. Research at von Bergmann's clinic, described in this article, has demonstrated that these Babes-Ernst bodies are the result of the condensation and localization of the euchromatic substance of the bacterial cell, and that this euchromatic substance is the germ-plasma, while the rest of the cell is merely the nutritive plasma. When the bodies occur in many or all of the individuals of a species they indicate that this species is at its highest point of vital and functional activity and living in its natural environment. The further removed the generation from this environment, the fewer bodies are found, but they increase again on return to it. When the vitality is most intense the bodies are the smallest and stain most decidedly, while the rest of the bacterial body stains the least, probably because all the euchromatic substance is included in the bodies. When the species is in a pure culture, apart from injurious influences, such as bactericidal secretions and danger of being overwhelmed by another species, it becomes torpid and loses its energy, its specific virulence. It can be aroused, however, even when half dead, and stimulated to renewed vital and functional vigor by being passed through the body of a living animal or by symbiosis with other bacteria on a plate of agar-agar. The bacterium, as soon as it enters the circle of existence of another organism, has to put forth all its energies to maintain itself in the struggle for existence, and the exertion of all its powers is shown in the formation of the Babes-Ernst bodies in its interior. These discoveries suggest that infection is in its essence the vital expression of the parasitism of a microbe in its highest potency, and that the route from the condition of a saprophyte to that of a parasite leads through morphologic transformation. We can watch a bacterium traveling this route when we pass specimens with rare Babes-Ernst bodies through a living animal which succumbs to them. When they emerge every individual contains one of these bodies. Or, again streptococci and other bacteria may be present in human saliva, with the bodies rare. If erysipelas of the face ensues, the streptococci will be found more numerous in the saliva and every coccus will contain a Babes-Ernst corpuscle. Marx therefore deduces from his extensive research on numerous species of bacteria that a bacterium accomplishes its transition from a non-infecting non-virulent to an infecting virulent micro-organism by the occurrence in its body of the condensation and localization of the euchromatic substance, which leads to the formation of the Babes-Ernst bodies. The number of individuals containing these corpuscles is therefore a measure of the virulence at the time, and the capacity of the cells to form these corpuscles is the criterion of their future virulence. He is now engaged in research to determine the factors involved in the production of this capacity. He begs others to test his assertions with fresh pus, sputa, etc., employing the technique he described in his first communication on the subject in the *Cbl. f. Bakteriologie*, July 11 to August 9, 1900, Nos. 1 to 5: Thickly spread and dried cover-glass preparations mounted in balsam, after having been passed three times slowly through a flame, are treated first with methylene blue—mixed Loeffler's, alcohol-aqueous and acetic—for five to ten seconds, then rinsed briefly with water and stained with bismarck brown—vesuvin—at 2 per thousand, for fifteen seconds. No special heat is applied. The bodies in the bacteria stain from deep blue to bluish red. The rest of the body is brown. As the bodies take the stain more readily and more intensely the greater the virulence of the bacteria, examination of their behavior to the stain is direct evidence of their virulence and of the gravity of the infectious process whence they were derived.

Therapie der Gegenwart (Berlin), September.

Treatment of Cholelithiasis. B. Naunyn.—In this review of the modern consensus of opinion in regard to the treatment of cholelithiasis, Naunyn states that he has observed four recurrences after operations for removal of gall-stones. He favors measures to soothe instead of stimulate peristalsis, and believes that Carlsbad waters probably owe their effect to the increased supply of blood in the abdominal organs which they induce. Their benefits can be enhanced by the application of heat, cataplasms or the thermophore, to the liver.

Important Relations of Fat Food to Gastric Functions. H. Strauss.—Hyperacidity of the stomach and disturbances in the motility are favorably influenced and to a marked degree by fats, and especially milk fats, cream and butter. Large amounts of milk fats diminish the gastric secretions, but do not prolong the length of time the ingestum remains in the stomach nor interfere with intestinal digestion in hyperacid patients, who always relish these fats better than large amounts of carbohydrates. During the last three years this method of treatment has been almost constantly followed at Senator's clinic in cases of ulcus ventriculi, hyperacidity or motor insufficiency. One patient throve well on two quarts of milk a day and half a pound of butter. A colleague with ulcus promptly gained twenty pounds in weight.

Sanatorium Treatment of Tuberculosis. S. Kaminer.—The most important factor in sanatorium treatment is an early diagnosis, and for this reason Kaminer urges compulsory examination of members of sick-benefit societies four times a year.

Oil in Case of Stenosis of the Pylorus. Cohnheim.—Oil relieves the contraction, is healing and nourishing and is an invaluable aid in case of stenosis of the pylorus. He gives 200 to 250 gm. of warm olive-oil in three doses, or all at once, one hour before meals, by the mouth or through a sound.

Wiener Klinische Wochenschrift, September 20.

Inhalations as Preventive of Scarlet Fever and Measles. J. Elgart.—The author's experience has convinced him that the throat affection in exanthematous diseases is primary and in reality the essence of the disease. He consequently reasoned that prompt sterilization of the throat would abort or prevent the disease. He is assistant physician at a large children's hospital where epidemics of scarlet fever and measles have been of frequent occurrence, children succumbing who had entered the hospital merely for ear or eye troubles, etc. In 1897 he inaugurated a system of inhalations, requiring every child to stand for five minutes in front of a spray apparatus and inhale the spray for five minutes twice a day. The disinfectant used was a 3 per cent. solution of boric acid or lime-water, or iodin trichlorate in a .05 per cent. solution. The number of children thus treated was 214, and not a single case of either scarlet fever or measles occurred during the year. During a temporary absence the inhalations were suspended and three cases of scarlet fever or varicella developed. On his return the inhalations were resumed and there has not been a case since to date. He observes that it is less expensive to sterilize the nose and throat of the patient than to disinfect a suite of rooms. If the experience of others confirms his results, we can assume that inhalations of a disinfectant fluid will prevent epidemics of scarlet fever and measles, at least when the type of the epidemic in the environment is mild. In 510 cases previously noted in the hospital the presence of an angina is mentioned in every case except eight. In two of these no inquiry was made in regard to the condition of the throat and in the rest not until about the sixth day, when a pre-existing angina might have had time to subside.

Klinitchesky Journal (Moscow), August.

Experimental Medicinal Cure of Gall-Stone Affections. N. D. Titoff.—Tests on nine large dogs are described in which the gall-bladder was incised and one or two human cholesterin calculi inserted. The wound was then closed and efforts made to dissolve the calculi by medicinal measures. They were successful beyond anticipation. If confirmed by future experience the fact is established that gall-stones can be artificially dissolved by way of the intestinal and biliary passages. Three Pravaz syringefuls of a mixture of 1 part ether to 2 parts benzol were injected per rectum. The injections were well retained and no local nor general unfavorable symptoms were observed. Traces of cholesterin crystals could be found in the bile aspirated even as soon as a half hour afterward. The stone had lost 16.5 mg. in weight when the animal died, two weeks after these injections had been inaugurated, in one case. These experiments demonstrate that the medicinal treatment of gall-stones has a solid foundation and that the only problem is to administer the benzol or other dissolvant in the least irritating form, possibly as terpin hydrate with euchinin or turpentin and quinin. In some of the experiments no medicine was used, but the stone diminished .013 to .01545 mg. The chloroform given during the operation may have been responsible in one case, but in the other no chloroform was used. This result seems to indicate that the natural bile of dogs is able to dissolve cholesterin calculi in certain cases at least.

Anales de Oftalmologia (Mexico), September.

Ocular Affections in the Negro. Santos Fernandez.—This number of the *Anales* contains a full report of the ophthalmic section at the International Medical Congress, in which Santos Fernandez took a prominent part. He stated, among other communications, that the negro is comparatively exempt from ocular affections, and especially from disturbances of the lachrymal canals, which are unusually large. In his experience during the last twenty-five years in Cuba he has only had 3003 negro and 2528 mulatto patients out of a total of 28,000 ophthalmic cases. He adds that the negro seems to be comparatively immune to affections of all kinds.

Books and Pamphlets.

Acknowledgement of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review as dictated by their merits, or in the interest of our readers.

BOOKS.

Progressive Medicine. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Hobart A. Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia, Assisted by Charles Adams Holder, M.D., Assistant Demonstrator of Therapeutics in the Jefferson Medical College. Volume iii. September, 1900. Diseases of the Thorax and Its Viscera, Including the Heart, Lungs and Blood-vessels; Diseases of the Skin; Diseases of the Nervous System; Obstetrics. Cloth. Pp. 408. Price $10.00 per year. Philadelphia and New York: Lea Brothers & Co. 1900.

The Student's Medical Dictionary, Including All the Words and Phrases Generally Used in Medicine,, With Their Proper Pronunciation and Definitions. Based on Recent Medical Literature. By George M. Gould, A.M., M.D., Editor Philadelphia Medical Journal. With Elaborate Tables of the Bacilli, Micrococci, Leucomains, Ptomains, etc.; of the Arteries, Ganglia, Muscles and Nerves; Weights and Measures, Analyses of the Waters of the Mineral Springs of the United States, etc., and a New Table of Eponymic Terms and Tests. Eleventh Edition, Enlarged with many Illustrations. Cloth. Price, $2.50. Philadelphia: P. Blakiston's Son & Co. 1900.

You and Your Doctor. How to Prolong Life. A Practical Book on Health and the Care of It. A Fearless Exposé of All Quacks and Frauds Within and Without the Medical Profession. By William B. Doherty, M.D., Member of the Kentucky State Medical Society. Illustrated. Cloth. Pp. 260. Price, $1.00. Chicago: Laird & Lee.

A Treatise on Mental Diseases. Based upon the Lecture course at the Johns Hopkins University, 1899, and Designed for the Use of Practitioners and Students of Medicine. By Henry J. Berkley, M.D., Clinical Professor of Psychiatry, Johns Hopkins University. With Frontispiece, Lithographic Plates and Illustrations in the Text. Cloth. Pp. 601. Price, $5.00. New York: D. Appleton & Co. 1900.

A Manual of Otology. By Gorham Bacon, A.B., M.D., Professor of Otology in Cornell University Medical College, New York; with an Introductory Chapter by Clarence John Blake, M.D., Professor of Otology in Harvard University. Second Edition, Revised and Enlarged. With 114 Illustrations and 3 Plates. Cloth. Pp. 422. Price, $2.25. New York and Philadelphia: Lea Brothers & Co. 1900.

A Treatise on Diseases of the Nose and Throat. By Ernest L. Shurly, M.D., Vice-President and Professor of Laryngology and Clinical Medicine, Detroit College of Medicine. Illustrated. Cloth. Pp. 744. Price, $5.00. New York: D. Appleton & Co. 1900.

The Physical Signs in Pulmonary Disease. By Graham Steell, M.D., Fellow of the Royal College of Physicians of London. For the Use of Clinical Students. Second Edition. Cloth. Pp. 98. Price, $1.25. Philadelphia: P. Blakiston's Son & Co. 1900.

The Use of the Sphygmograph in Clinical Medicine. By Graham Steell, M.D., F.R.C.P., Physician to the Manchester Royal Infirmary. Cloth. Pp. 57. Price, $1.00. Philadelphia: P. Blakiston's Son & Co. 1900.

Transactions of the American Surgical Association. Volume xviii. Edited by De Forest Willard, M. D., Ph.D., Recorder of the Association. Cloth. Pp. 468. Printed for the Association. For Sale by William J. Dornan, Philadelphia. 1900.

Transactions of the Louisiana State Medical Society, at its Twenty-First Annual Session, held at New Orleans, La., April 19, 20, 21, 1900. Cloth. Pp. 427.

Warner's New Therapeutic Reference Book. By William R. Warner. Cloth. Pp. 225. Price, 0.25. W. R. Warner & Co.

Transactions of the Ohio State Medical Society, at its Fifty-Fifth Annual Meeting, held at Columbus, Ohio, May 9, 10, 11, 1900. Cloth. Pp. 422. Cleveland, Ohio: J. B. Savage.

Transactions of the North Dakota State Medical Society for the year 1899, and List of Members. Paper. Pp. 136. St. Paul, Minn.: Northwestern Lancet. 1899.

Medical Diseases of Infancy and Childhood. By Dawson Williams, M.D., Fellow of the Royal College of Physicians of London. Second Edition Revised with Additions by Frank Spooner Churchill, M.D., Instructor in Diseases of Children, Rush Medical College. Illustrated witht 72 Engravings and 2 Colored Plates. Cloth. Pp. 542. Price, $3.50 net. Philadelphia and New York: Lea Brothers & Co., 1900.

Manual of the Diseases of the Eye. For Students and General Practitioners. With 243 Original Illustrations including 12 Colored Figures. By Charles H. May, M. D., Chief of Clinic and Instructor in Ophthalmology, College of Physicians and Surgeons, New York. Cloth. Pp. 406. Price, $2.00. New York: William Wood & Co. 1900.

Transactions of the Vermont Medical Society. D. C. Hawley, M.D., Secretary. Annual Meeting in 1900, at Rutland, Oct. 11 and 12. Cloth. Pp. 231. Burlington, Vt.: Free Press Association. 1900.

A Child of Light, or Heredity and Prenatal Culture. Considered in the Light of the New Psychology. By Newton N. Riddell. Cloth. Pp. 351. Price, $2.00. Chicago: Child of Light Publishing Co. 1900.

Twenty-sixth Annual Report of the Secretary of the State Board of Health of the State of Michigan for the Fiscal Year Ending June 30, 1898. Cloth. Pp. 395. Lansing, Mich.: Robert Smith Printing Co. 1900.

Transactions of the Medical Society of the State of New York, for the Year 1900. Cloth. Pp. 522. Published by the Society. 1900.

The Book of the Rules of the Medical Association of the State of Alabama. Cloth. Pp. 243. Montgomery, Ala.: Brown Printing Co. 1889.

PAMPHLETS.

A Case of Malta Fever. Amyloid Disease of the Liver with an Abnormally Enlarged Left Lobe. Cancer of the Common Bile-Duct. Indications for the Use of Alcoholic Stimulants in Typhoid Fever. On the Use of Antitoxin in Diphtheria: With Special Reference to Small and Frequently Repeated Doses. By John H. Musser, M.D., Philadelphia. Reprints.

A Crushable Button as an Aid to Suturing in Intestinal Anastomosis. By R. C. Coffey, M.D., Portland, Ore. Reprinted from the Med. Sentinel.

A Study of Diabetes—Its Nature, Cause and Cure. By S. G. Hubbard, M. D., New Haven, Conn. Reprinted from Proceedings of Conn. Med. Society.

Cerebral Localization. Hypnotism in Therapeutics. By Sydney Kuh, M.D., Chicago. Reprints.

Especial Hospitals for Consumption Among the Poor in our Cities. By Edward O. Otis, M.D., Boston, Mass. Reprinted from Phila. Med. Jour.

How Shall Boards of Health Proceed to Prevent the Spread of Communicable Diseases? The Patient's Secret. By Daniel Strock, M.D., Camden, N. J. Reprints.

Observations on the Treatment of Epilepsy. By A. N. Williamson, M.D., New Haven, Conn. Paper. Pp. 15. New Haven, Conn.: E. E. Darrow. 1900.

Presentation of the Code of Ethics. By W. P. Munn, M.D., Denver, Colo. Reprinted from Denver Med. Times.

Some Cases of Dilatation of the Stomach. By John H. Musser, M.D., Philadelphia, and J. Dutton, Steele, M.D., Philadelphia. Reprinted from Am. Jour. of Med. Sciences.

Some Problems Concerning Nervous Disease. By F. W. Langdon, M.D., Cincinnati, Ohio. Reprinted from Brooklyn Med. Jour.

The Diagnosis of Hysteria. Two Cases of General Anesthesia. By Charles W. Burr, M.D., Philadelphia. Reprints.

Total Excision of the Scapula Alone and with the Arm (Interscapulo-Thoracic Amputation); Partial Excision of the Scapula for Tumor. By J. J. Buchanan, M.D., Pittsburg, Pa. Reprinted from Phila. Med. Jour.

Transactions of the Ophthalmologic Division of the Western Ophthalmologic and Oto-laryngologic Association, at its Fifth Annual Session, held in St. Louis, Mo., April 5, 6 and 7, 1900. Paper. Pp. 64. St. Louis, Mo.: American Journal of Ophthalmology.

Abnormal Electrical Storage in the Human System. James Grant, M.D., F.R.C.P., Ottawa. Reprinted frfom Montreal Med. Jour.

Abortion. A. D. Wilkinson, Lincoln, Neb. Reprinted from Western Med. Review.

A Case of Cataracta Nigra, with Specimen, and a Case of Pulsating Exophthalmos, with Patient. Geo. C. Pardee, Ph. B., A.M., M.D., San Francisco, Cal. Reprinted from Transactions of Med. Society of State of California.

A Case of Paralysis Agitans—Cure. Nathan Herman, M.D., Baltimore. Reprinted from Md. Med. Jour.

Chronic Lacunar Tonsilitis. Charles E. Clark, M.D., Kansas City, Mo.

Acute Enlargement of the Thyroid Gland, With Report of Cases. Aortic Regurgitation with Remarks upon Flint's Murmur and Paroxysmal Sweating. The Immediate and Remote Effects of Athletics upon the Heart and Circulation. The Diagnosis of Chlorosis and Chloroanemia. Alfred Stengel, M.D., Philadelphia. Reprints.

An Essay on the Reduction of Obeisity: A Reliable and Harmless Way to Diminish and Cure Over-Fatness. By William T. Cathell, A.M., M.D., Baltimore. Reprinted from Md. Med. Jour.

Annual Report of the Board of Health of the City of Lancaster, Pa., for the Fiscal Year Ending December 31, 1899. Paper. Pp. 149. Lancaster, Pa.: Halbach, Printer.

Charges, Evidence and Arguments on Which Dr. J. F. Baldwin Was Expelled as Chancellor and Professor of Operative Gynecology by the Trustees of the Ohio Medical University. Paper. Pp. 128. Columbus, Ohio: The Landon Printing and Publishing Co. 1899.

Charles Frederick Wiesenthal, Medicinae Practicus, the Father of the Medical Profession of Baltimore. Eugene F. Cordell, M.D., Baltimore. Reprinted from Johns Hopkins Bulletin.

Conservative and Radical Surgery of Empyema. O. Thienhaus, M.D., Milwaukee, Wis. Reprinted from Milwaukee Med. Jour.

Formalin Disinfection of Baggage Without Apparatus. Preliminary Note on the Viabality of the Bacillus Pestis. M. J. Rosenau, Washington, D. C.

Notes on Three Unique Autopsies. Wm. H. Hancker, M.D., Wilmington, Del. Paper. Pp. 18. Wilmington, Del.: Star Print. 1899.

Sixth International Otological Congress, London. Aug 8 to 12, 1899. Transactions Edited under the Direction of the Editorial Committee by E. Cresswell Baber, Hon. Secretary-General. Paper. Pp. 477. London: Southern Publishing Co. 1900.

TRADE PAMPHLETS.

Illustrated Catalogue of Batteries and Electro-Therapeutical Appliances. Paper. Pp. 96. McIntosh Battery and Optical Co., Chicago.

Talks on Rubber. Paper. Pp. 143. Riker's Drug Store, New York.

New Patents.

Patents of Interest to physicians, etc., Sept. 18 to 25:

658,250. Chemical apparatus. Ferdinand R. K. Erfmann, Rotterdam, Netherlands.

658,111. Shoulder-brace. Louise S. Long, San Francisco, Cal.

658,273. Package for medicines, etc. Luther E. Moore, Marietta, Ga.

658,217. Lifting device for hospital beds. Elbert E. Munger, Spencer, Iowa.

658,027. Therapeutic device. Andrew W. Steiger, Boston, Mass.

33,215. Design, water-bag. George S. Van Pelt, New York City.

33,216. Design, fountain syringe-bag. George S. Van Pelt, New York City.

658,481. Massage apparatus. Oscar C. A. Carlsson, Stockholm, Sweden.

658,436. Insufflator. Hans H. Groth, Cincinnati, Ohio.

658,651. Hernial truss. John C. Keil, LaPorte, Ind.

658,669. Speculum. John W. Morrow, Nobility, Texas.

658,467. Device for adjusting truss-pads. Andrew B. C. Sawyer, Albany, N. Y.

658,468. Respiratory mask. Daniel W. Schaeffer, Dayton, Ohio.

658,411. Ionone derivatives and making the same. Johann C. W. F. Tiemann, Berlin, Germany.

658.601. Appliance for imparting heat and electricity to the body. Ignaz Timar, Berlin, Germany.

Change of Address.

Jos. H. And, Cecilian, Ky., to Blackwell, O. T.

H. L. Artz, St. Paul, Minn., to 290 Marshfield Ave., Chicago.

L. D. Alexander, Jr., New Canaan, Conn., to University of Virginia, Charlottesville, Va.

M. P. Bachman, Waterloo, to Muchakinock, Iowa.

P. T. Conlon, Columbus to Platte Center, Neb.

G. F. Chambers, Fort Mitchell, Ala., to Grady Hospital, Atlanta, Ga.

J. C. Dunn, 759 W. 47th St., to 2529 Indiana Ave., Chicago.

H. E. Dearholt, 560 Maryland Ave., to Camp Bldg., Wisconsin and Water Sts., Milwaukee, Wis.

R. C. Fullenwider, Chicago, to Clinton, Ill.

A. M. Fauntleroy, Staunton, to University of Virginia, Charlottesville, Va.

H. D. Gray, Kellogg, to Newton, Iowa.

E. S. Godfrey, Ottawa, O., to 418 S. Broad St., Philadelphia, Pa.

J. H. Holman, Cincinnati, Iowa, to Hartford, Mo.

Geo. L. Hoel, West Liberty, Ill., to Box 823, Ft. Collins, Colo.

E. B. Hults, Gant, to Mexico, Mo.

S. B. Lyon, 8 Mason St., to 330 Eddy St., San Francisco, Cal.

B. F. Long, McCoysville, to Blair's Mills, Pa.

LeRoy Lewis, Chicago, to Bay City, Mich.

J. F. Oechsner, 1229 Elysian Field, to 738 Frenchman [illegible] Orleans, La.

C. H. McElfresh, Dawson, to 1016 W. Monroe St., Sp [illegible]

J. Merenna, 1 Charleston St., New York City, to 1 [illegible] Brooklyn, N. Y.

Susanne Orton, Darlington, Wis., to 298 Maxwell St., care Lying-in Dispensary, Chicago.

I. M. Pfouts, Beach City, to Adams Mills, Ohio.

E. R. Steen, Wheatland, Ind., to 216 Sterling Ave., Joliet, Ill.

H. M. Whiteway, 4336 Sansom St., to 1924 Chestnut St., Philadelphia, Pa.

J. Wehrly, Union Trust, to Chemical Bldg., St. Louis, Mo.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Sept. 27 till Oct. 3, 1900, inclusive:

Cosam J. Bartlett, acting asst.-surgeon, from the Department of California to duty at Port Valdez, Alaska.

Edward C. Carter, major and surgeon, U. S. A., member of a board convened at Washington, D. C., to examine officers of the medical department for promotion.

Edward T. Comegys, major and surgeon, U. S. A., will ship to Manila, P. I., all medical supplies at Taku, China, not required by the troops to remain in China and will report at Manila for duty as medical supply officer at that place.

Joseph J. Curry, acting asst.-surgeon, relieved from duty as a member of the board appointed Jan. 16, 1900, to study tropical diseases in Manila, P. I.

Euclid B. Frick, captain and asst.-surgeon, U. S. A., from Ft. Wadsworth, N. Y., to San Juan, P. R., for duty in the Department of Porto Rica.

Guy C. M. Godfrey, captain and asst.-surgeon, U. S. A., to San Francisco, Cal., to accompany troops to Manila, P. I., and for duty in the Division of the Philippines.

Albert Hartsuff, colonel and assistant surgeon-general, U. S. A., leave of absence granted, with permission to go beyond sea.

John Van R. Hoff, major and surgeon, U. S. A., relieved from further duty with troops in China, to proceed to San Francisco, Cal., and report by telegraph to the surgeon-general at Washington, D. C.

Jefferson R. Kean, major and surgeon, U. S. A., member of a board convened at Columbia Barracks, Quemados, Cuba, to examine officers of the medical department for promotion.

Preston S. Kellogg, acting asst.-surgeon, from Battle Creek, Mich., to Fort Keogh, Mont., for post duty.

Thomas J. Kirkpatrick, lieutenant and asst.-surgeon, U. S. A., to report at Washington, D. C., for examination for promotion.

Muhlenberg K. Knauff, acting asst.-surgeon, from Fort Keogh, Mont., to St. Paul, Minn., for annulment of contract.

Edgar A. Mearns, captain and asst.-surgeon, U. S. A., to report at Washington, D. C., for examination for promotion.

James C. Merrill, major and surgeon, U. S. A., member of a board at Washington, D. C., to examine officers of the medical department for promotion.

Henry Page, lieutenant and asst.-surgeon, U. S. A., leave of absence granted.

Walter Reed, major and surgeon, U. S. A., president of a board convened at Columbia Barracks, Quemados, Cuba, to examine officers of the medical department for promotion.

Alexander N. Stark, captain and asst.-surgeon, U. S. A., leave of absence extended; member of a board at Columbia Barracks, Cuba, to examine officers of the medical department for promotion.

W. J. S. Stewart, acting asst.-surgeon, now on leave of absence, to temporary duty on the transport *Rawlins*.

John H. Stone, lieutenant and asst.-surgeon, U. S. A., to report at Columbia Barracks, Quemados, Cuba, for examination for promotion.

Neil C. Trew, acting asst.-surgeon, from Port Valdez, Alaska, to San Francisco, Cal., for duty in the Department of California.

George M. Wells, captain and asst.-surgeon, U. S. A., from San Juan, Porto Rico, to duty at Fort Wadsworth, N. Y.

Alfred A. Woodhull, lieutenant-colonel, deputy surgeon-general, U. S. A., president of a board convened at Washington, D. C., to examine officers of the medical department for promotion.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy for the week ending Oct. 6, 1900:

Surgeon J. C. Byrnes, detached from the *Massachusetts*, Oct. 1, and ordered to the New York navy yard.

Medical Inspector J. R. Waggener, detached from duty at naval hospital, Yokohama, Japan, and ordered to duty in charge of the naval hospital, Cavite, P. I.

Asst.-Surgeon B. L. Wright, detached from the *Isla de Luzon* and ordered to the naval hospital, Cavite, P. I.

P. A. Surgeon L. L. Von Wedekind, detached from the *Richmond* and ordered to the Puget Sound naval station.

P. A. Surgeon R. S. Blakemen, detached from the naval training station, Newport, R. I., [illegible] ordered to temporary dury on the *Pen* [illegible] *ola.*

Surgeon [illegible] o the nav [illegible] wport, [illegible] uty.

[illegible] geon [illegible] om [illegible] ng [illegible] ica [illegible] e [illegible] t

Station and ordered to proceed home and to be ready for orders to sea duty.

P. A. Surgeon W. F. Arnold, ordered to the naval recruiting rendezvous, Chicago, Ill., Oct. 8.

Surgeon S. H. Dickson, detached from the Washington navy yard and ordered to duty at the headquarters of the Marine Corps, Washington, D. C.

Surgeon C. G. Herndon, detached from the naval museum of hygiene, Washington, D. C., October 8, and ordered to duty at the Washington navy yard.

Surgeon E. H. Green, detached from duty at the headquarters of the Marine Corps, Washington, D. C., and ordered to wait orders.

Surgeon E. H. Green, ordered to the *Alabama*, Oct. 16.

Asst.-Surgeon T. M. Lippitt, detached from the *Monocacy* and ordered to the naval hospital, Yokohama, Japan, for treatment.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ending Sept. 27, 1900:

Surgeon F. W. Mead, granted leave of absence for one day.

Surgeon D. A. Carmichael, granted leave of absence for thirty days from Oct. 15.

P. A. Surgeon C. P. Wertenbaker, granted leave of absence for three days.

Asst.-Surgeon M. H. Foster, to proceed to Port Angeles, Washington, for special temporary duty.

Asst.-Surgeon Dunlop Moore, relieved from duty at Dutch Harbor, Alaska, and directed to proceed to San Francisco, Cal., or Seattle, Wash., and await orders.

Asst.-Surgeon Carroll Fox, relieved from duty at Dutch Harbor, Alaska, and directed to proceed to San Francisco, Cal., or Seattle, Wash., and await orders.

A. A. Surgeon R. S. Primrose, granted leave of absence for seven days from Sept. 24.

A. A. Surgeon W. S. Walkley, granted leave of absence for eleven days from Sept. 24.

A. A. Surgeon W. O. Wetmore, relieved from duty at Cape Charles quarantine, and directed to proceed to Buffalo, N. Y., and report to medical officer in command for duty.

Hospital Steward G. C. Allen, granted leave of absence for five days under paragraph 181, Regulations, M.-H. S.

Hospital Steward Myron R. Mason, relieved from duty at Dutch Harbor, Alaska, and directed to proceed to San Francisco, Cal., or Seattle, Wash., and await orders.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Oct. 6, 1900:

SMALLPOX—UNITED STATES.

Colorado: Sept. 18-24—Garfield County, 1 case; Larimer County, reported; Las Animas County, 2 cases; Pueblo County, 11 cases; total, 14 cases, 1 death.
Kansas: Wichita, Sept. 22-29, 1 case.
Louisiana: New Orleans, Sept. 22-29, 1 case, 1 death.
Ohio: Cleveland, Sept. 22-29, 6 cases.
Oregon: Portland, Sept. 5, 3 cases.
Utah: Salt Lake City, Sept. 22-29, 3 cases.
Washington: Tamcoa, Sept. 22-29, 1 case.

SMALLPOX—FOREIGN AND INSULAR.

Belgium: Ghent, Sept. 1-15, 2 deaths.
Egypt: Cairo, Aug. 26-Sept. 2, 2 deaths.
England: Liverpool, Sept. 8-15, 1 case, 1 death; London, Sept. 1-15, 6 cases.
France: Paris, Sept. 8-15, 12 deaths.
India: Calcutta, Aug. 25-Sept. 1, 5 deaths; Karachi, Aug. 26-Sept. 2, 2 cases, 1 death; Madras, Aug. 20-31, 3 deaths.
Japan: Formosa, July 1-31, 3 cases.
Mexico: City of Mexico, Sept. 2-16, 13 cases, 7 deaths.
Philippines: Guimeras, Aug. 20, 20 cases.
Russia: Moscow, Sept. 2-9, 2 cases; Odessa, Sept. 8-15, 6 cases, 3 deaths; St. Petersburg, Sept. 1-8, 22 cases, 12 deaths; Vladivostock, May 1-July 31, 3 cases; Warsaw, Sept. 1-8, 9 deaths.
Scotland: Glasgow, Sept. 8-22, 26 cases, 1 death.

YELLOW FEVER.

Colombia: Barranquilla, Sept. 8-16, 1 death; Cartagena, Aug. 31-Sept. 14, 3 cases, 3 deaths.
Cuba: Havana, Sept. 15-22, 9 deaths.

CHOLERA.

India: Bombay, Aug. 28-Sept. 4, 177 deaths; Calcutta, Aug. 25-Sept. 1, 4 deaths; Karachi, Aug. 26-Sept. 2, 11 cases, 10 deaths; Madras, Aug. 25-31, 44 deaths.
Japan: Fukuoka Ken, Aug. 28, 4 cases; Osaka and Hiogo, Aug. 18-25, 1 case.
Straits Settlements: Singapore, July 28-Aug. 4, 1 death.

PLAGUE—FOREIGN AND INSULAR.

Brazil: Rio de Janeiro, Aug. 1-31, 90 cases, 46 deaths.
Egypt: Alexandria, Aug. 20-27, 2 cases, 2 deaths.
India: Bombay, Aug. 28-Sept. 4, 57 deaths; Calcutta, Aug. 25-Sept. 1, 56 deaths.
Japan: Formosa, Taihoku Ken, July 31-Aug. 7, 3 cases, 4 deaths.
Philippines: Cebu, July 25, 1 American boy; Manila, July 28-Aug. 18, 10 cases, 5 deaths.
Scotland: Glasgow, Sept. 18, 7 cases, 1 death.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

Original Articles.

LARNYGEAL STENOSIS DUE TO COMPLICATION OF THE THYROID CARTILAGES.*

EMIL MAYER, M.D.

Surgeon to the New York Eye and Ear Infirmary (Throat Dept.);
Fellow of the American Laryngological Assn., etc.

NEW YORK.

In November, 1898, Private Jacob H. M., Fourth U. S. Infantry, came under my observation. He was entirely aphonic and breathed through a tracheotomy tube. With pencil and paper all queries were intelligently answered and the following history was elicited:

He was in the second year of a second enlistment. While lying down on the fighting line at the battle of El Caney, July 2, 1898, he received a wound over the right frontal bone, from a Mauser bullet. His sensations at that time were such as follow a stunning blow, though there was no loss of consciousness, for he remembered everything that occurred. There was some slight bleeding from the bullet's point of impaction and very profuse bleeding from the mouth and nose. There was a sensation of rasping as though a saw was passing up and down through his head on the right side, and he had difficulty in getting air enough, for it seemed to escape somewhere before it got into his lungs. With it all he had a severe chill.

In about three hours litter-bearers arrived and carried him to a field-hospital, where his wound was dressed. Some water given him produced strangling and he found that he could not swallow; his thirst was assuaged by moistening a piece of gauze and placing it between his teeth, the jaws were quite firmly wedged together by this time. The jaws slowly relaxed and six days later, July 8, he was able to swallow a little at a time. A long string of tissue hung from his mouth; this he pulled away with his fingers. He had been transferred first to the division hospital and then to the ship *Relief*. On board the ship he began to eat, but not without strangling. He was then placed aboard the transport ship *Seneca* for return to this country. There the fare consisted of hardtack and coffee, and after three days bacon was added; some of this he swallowed. During all this time he had not slept six hours because of constant noises in his head. On July 26, 1898, he landed, and was sent with other wounded soldiers to a general hospital in New York City. He described a terrible choking sensation occurring soon after his admission to the hospital, following an attempt to swallow whisky and oil. His breathing was always difficult at that time; a walk of ten paces exhausted him. His breathing became more difficult each day, and on August 3 tracheotomy was performed, followed by complete relief. His dysphagia was much better, and he partook of solid food. One night while at stool, after much straining, a metallic substance passed from his rectum; no attempt was made to recover it. His history obtained from this hospital is as follows:

Soldier U. S. A., age 25, admitted July 26, 1898. Father living, good health. Mother died at 57 of typhoid fever, three brothers living aged 34, 30, 19, in good health. Two sisters, 28, 20, good health.

Personal history:—He had typhoid fever in 1894; general health good; on July 1 at El Caney was shot with Mauser bullet above right eye, *glancing wound;* dressed at division hospital and recovered rapidly; was exposed to rain-storm shortly after, and from that time has been very hoarse, expectorated considerably, voice husky; on admission was hoarse and later on inspiration there was a retraction of the supra- and infraclavicular spaces, with considerable difficulty in breathing. Dyspnea increased and on August 3 tracheotomy was performed under cocain, followed by relief to dyspnea. Diagnosis: "Stricture larynx."

December 5 he was transferred to New York Eye and Ear Infirmary.

Examination:—Over the frontal bone on the right (Fig. 1) there is a scar 20 mm. in length and 5 mm. in breadth. The lowest point is 3.5 mm. from the external canthus and curves to a point about 4 mm. from the center of the supraorbital notch. In the pharynx there is a notable absence of the greater portion of the posterior fold of the soft palate on the patient's right, some of it near the uvula and again near the tonsil being present. It presents the appearance of being gouged out. Alongside the tonsil is a line of reddened tissue which looks as though this fold had descended and become adherent. The left side is entirely normal.

Laryngoscopic examination:—A mass of mucus lies within the larynx, which is very tenacious and difficult of removal. An infundibulum is seen closed tightly and not even admitting a small probe. No air passes through. The inner wall of the larynx bulged at the center and the lowest portion [illegible] a line with the site of the false vocal cords. There [illegible] voice sounds whatever.

The clean-cut hole in his soft palate [illegible] minuted appearance of his larynx, [illegible] history, led to the diagnosis of a [illegible] shot wound, the bullet taking a [illegible] course.

Instead of his having had a [illegible] surgeons heretofore had believ[illegible] rectly alongside and over the [illegible] the superior maxilla [illegible] through the posterior [illegible] entered the neck. *Presented to the Section on Laryngology and Otology at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

admitted to the service of Dr. Morris J. Asch, who agreed with my diagnosis and kindly placed him in my charge. Under cocain anesthesia attempts were made to pass the hard-rubber fenestrated Schrötter tube of small caliber. These were persistently used, and on January 10 dilatation was followed by an attack of coughing and a mass of lymph was coughed up. A large chink resulted, and some air could be inspired and he was able to speak in a hoarse but strong voice. During February various larger sized Schrötter tubes were introduced, the patient breathing through the fenestration at the lower end of the tube.

On March 7 a large sized O'Dwyer tube was inserted and after a few hours was coughed up.

March 20 he was again intubated under cocain, after many attempts; the tracheotomy opening was packed with gauze. He was unable to swallow with the intubation tube and he was fed by means of the stomach tube.

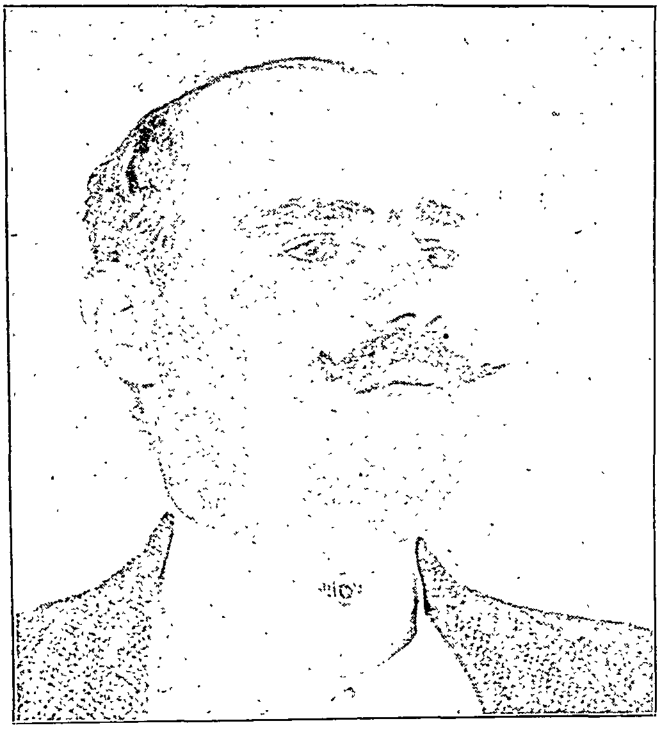

Fig. 1.—Cicatrix shows entrance of bullet.

March 24, in a severe coughing spell the tube was coughed up, after four days of intubation and the tracheotomy tube reinserted. The next day he was readily intubated, the tube remaining but one day *in situ,* the tracheal tube being again inserted. The Schrötter tubes readily enter.

April 17, an intubation tube was inserted, having a small rectangular piece screwed through the tracheotomy wound, into a hole previously made in the intubation tube. The screw of this was too short and the tube was coughed out four days later.

April 24, an adult intubation tube had been introduced and a heated iron passed through the tracheal wound to the tube thus marked the point opposite the opening. Following the suggestion of Dr. John Rogers, Jr., of this city, a large threaded opening was made in the intubation tube opposite the tracheal opening and the solid tube was made to screw in—a small plug being inserted to prevent its unscrewing when *in situ.* The final appearance is similar to the arrangement in glass described by Werner Kummel[1] of Breslau. This tube remained *in situ* for six weeks, the patient being fed every three hours by means of the esophageal tube inserted through the nose. During all this time he was unable to swallow. He breathes well, goes about, and enunciates clearly. A small piece of tissue flaps to and fro low down; some narrowing of the lumen of the larynx still exists. A new O'Dwyer tube with the Roger attachment was readily introduced. He left hospital on June 29, wearing this tube; he had meanwhile learned to feed himself by means of the esophageal tube. He was readmitted July 20, 1899.

The tube was removed and a large space was visible in his larynx. His voice was clear, his respirations free and the tube was not reinserted. The external opening was closed and daily applications were made to the thickened tissue in the larynx. His comfort was extreme, his voice clear and distinct; except for some loose flaps quite low down there was no visible abnormality. This comfort lasted for ten days, when the patient complained of some dyspnea and following an application to his larynx the dyspnea became extreme. This attack of dyspnea became so intense that I hastily operated in my office and introduced a tracheotomy tube.

August 1 he was reintubated, followed by a septic condition, and on August 5 tube was removed. From now on Schrötter tubes of increasing caliber were introduced daily until March 1, 1900, in the following manner. A 4 per cent. solution of cocain was sprayed into the larynx, the tracheotomy tube withdrawn, a Schrötter tube of very large caliber was introduced beyond the tracheal orifice, and the patient breathed through the tube, keeping it in position for twenty minutes. The tracheotomy tube was reinserted on the withdrawal of the Schrötter tube, the opening was corked up and patient breathed easily for fully two hours. The problem here was to find an intubation tube that would not be coughed up, would permit of deglutition when *in situ* and could be introduced with the least discomfort to the patient. It was noticed with regard to the latter point that Schrötter's tubes, being hollow all the way through, were readily introduced and were not at all annoying, while on the other hand the usual intubation tube with its introducer cut off the air to a most disagreeable extent and was difficult to insert. I therefore had made for me a tube whose head was as low as possible, with no retaining swell, and with a threaded opening for a screw piece, and finally a hollow introducer, which I here exhibit (Fig. 3). Intubation was as sim-

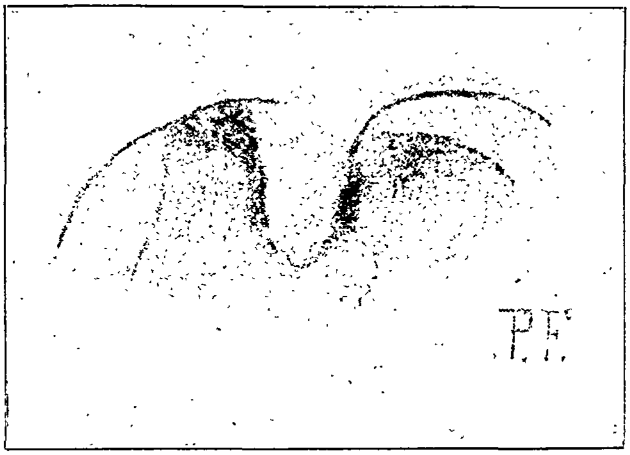

Fig. 2.— Showing hole made by bullet.

---

[1] Archiv f. Laryngologie, 1896, Vol. iv, p. 72.

ple and easy a problem as one could wish. The new tube was introduced and left *in situ.* In the meantime his general condition was so poor that he began to show some signs of sepsis and the tube was removed. He had been in the hospital, except one month, for a year and a half, and it was deemed advisable to send him to some army hospital where the change of air, combined with a rest from treatment to his larynx, would give him the opportunity to recuperate and enable us to conclude our methods at dilatation eventually. Accordingly he was transferred to Governor's Island in New York Harbor and within a month increased 20 pounds in weight. An examination of his larynx, June 1, shows some diminution of the space about the center of the thyroid cartilages, which appear as if bent in. The vocal cords are plainly visible and perform their function. Some narrowing of the space on a line with the cricoid still exists. His condition is materially improved and I see no reason why, with an intubation tube that permits deglutition, we may not eventually anticipate a perfect cure.

The points of interest in the case are the acceptance of a glancing wound of the frontal bone as a correct diagnosis by all surgeons until I saw him, the remarkable course of the bullet, which failed to injure his eye, important nerves or blood-vessels, the early restoration of his voice and the tolerance of his larynx to dilatation, and finally to the use of an entirely new method of intubation, which the writer hopes will render subsequent attempts at intubation, in chronic stenoses at any rate, much more agreeable to both the patient and to the physician.

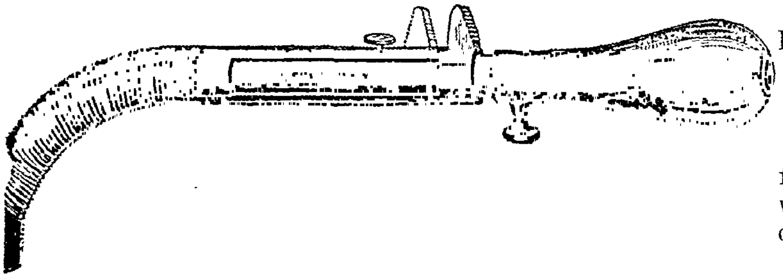

Figure 3.

DISCUSSION.

Dr. W. H. Daly, Pittsburg—These cases are very rare. Several years ago, I do not know how many, but some of the old members of the American Laryngological Association may remember, I collated all the cases I could find of gunshot wounds of the larynx, and they were very few in number. I made a very careful search in the Army Medical Museum and other places and could find only very few cases.

Dr. Cohen saw a case with me which was very interesting. A ball, I think a 22 caliber, had pierced the thyroid bone and had severed both true vocal cords. I saw the case about two weeks after the wound was sustained. At that time the young man was lying in a very critical condition. The ball had not been discovered, and with the attending surgeon we made a very careful search for the bullet. The ball had entered somewhere near the angle of the jaw in a downward direction. The boy was not able to speak. After a careful search we found a spot behind the collar bone of the opposite side, over which there was great tenderness. I suggested that we cut down on the parts, making a careful dissection, and while there was some objection, we finally prevailed, and we found the ball resting on the subclavian artery. Part of the coats of the artery was absorbed by the pressure. Certainly, in a very short time, the bullet would have caused ulcerative absorption and hemorrhage. Afterward I asked our eminent colleague, Dr. Cohen, to examine the patient. With the use of the laryngoscope he made a very careful examination, and I think we agreed that the boy would never have an audible voice. We did not see how it was possible with the amount of ulceration and traumatic damage done to the larynx. However, I brought the patient to Pittsburg, and after prolonged care he recovered, without much traumatic stricture of the larynx, and in about a year or a year and a half, he had an audible voice and afterward he became able to shout. He entered on the study of medicine, and is now a graduate, and can use his voice very well. The case shows the tremendous amount of damage that may be done to the larynx and pretty good results follow.

Dr. J. Holinger, Chicago—About five years ago a new tracheotomy tube was devised by Dr. Thilo, of Chicago. The instrument consists of two pieces on the principle of a duck bill. It would fully comply with all the requirements necessary for an intubation tube in this case. The instrument is very easy to be inserted, and deglutition is possible with the tube in situ. It is self-retaining. So far, this instrument has been buried in the reports of the Chicago Medical Society, and no instrument-maker is willing to take it up because there are so many varieties of the O'Dwyer tubes. But I know it is a good thing.

Dr. Emil Mayer, closing the discussion—I am desirous of knowing something about that tube, as it would be of advantage to procure one that will remain in the larynx.

PAPILLOMATA OF LARYNX IN CHILDREN.*

EDWARD T. DICKERMAN, M.D.
CHICAGO.

Papillomata of the larynx is undoubtedly the most frequent neoplasm found in the larynx of children, where fortunately pathologic growths are not of frequent occurrence.

In an article by Rosenberg,[1] of Berlin, he states that out of 5808 children under 13 years of age, 16 cases of papillomata were found, that is, 1 in 363 cases examined.

Schrötter found the ratio about 1 in 700, Baumgarten states the condition was rare in his clinic.

In my own clinic I find the disease occurring once in about every 1200 cases. It has been my fortune to see 5 of these cases, 3 in private and 2 in clinical practice, the histories of which I shall briefly relate:

Case 1.—In March, 1896, a little girl, aged 6 years, was brought from Montana to consult Dr. M. R. Brown, of this city. At the time, Dr. Brown was unable to take care of the child and he referred her to me. She gave the history of diphtheria two years before, since which time she has been gradually growing hoarse, and during the last six months breathing has become difficult. The general condition of the child was below par and it was with the greatest difficulty that a glimpse of the larynx was obtained, revealing nearly the entire cavity filled with a cauliflower growth of a pale greyish-white color. After consulting with Dr. Brown, I decided to first do a tracheotomy for the relief of the dyspnea. Five days later thyrotomy was done and the growth was found attached to the false and true cords and extending up on the inner side of the aryepiglottic fold. It was removed with scissors and curette; the base was cauterized with chromic acid. At the end of four weeks the mother insisted on taking the child home, and as no recurrence had taken place the tube was removed. The growth recurred five months later and tracheotomy was again done by the local physician.

Case 2.—In January, 1897, a boy, 9 years old, was sent to me from an interior town, with the following history: One year before, the boy had a sore throat and as hoarse. He belonged to a church choir and during his time had tried to sing, but his voice failed him. Since then he has been gradually growing worse. On xamination a lobulated growth was found springing rom the under side and free edge of the left cords nd at the angle extending across to the right cord. The oy had a good control of his larynx and by means of snare the growth was removed, only to recur. During even months, I operated five times, and then followed up my last operation with a 5 per cent. solution of alicylic acid in alcohol, to which was added 3 per cent. of resorcin applied daily. For two years the larynx has been free and the voice good.

[1] Archiv f. Laryngologie.

Case 3.—A girl, 5 years old, was brought to my clinic t the Chicago Policlinic, in June, 1898, with the history of scarlet fever eighteen months before, since that ime cough, hoarse crying, and later dyspnea. With great difficulty a glance into the larynx was obtained, revealing a warty growth filling in the anterior two-thirds of the glottis. Tracheotomy was done at once on account of the dyspnea. At repeated sittings, by means of a snare and sponge as devised by Voltilini, pieces of the growth were removed. I lost track of the child for six months and when she returned I found much to my surprise that the growth had disappeared. She wore the tube for six months and at the end of that time, no recurrence taking place, it was removed. I saw the little patient the other day. The larynx is free and the voice normal.

Case 4.—A boy, 2 years of age, was brought to my clinic last December with history of cough, laryngeal spasm, rough hoarse cry and for two weeks dyspnea. Only by means of the autoscope was I able to see the posterior part of the larynx, the surface of which was covered with a papillomatous growth. Tracheotomy was done at once, and from my last examination, made two weeks ago, I think the growth is growing smaller. No endolaryngeal treatment was employed.

Case 5.—A girl, 4 years old, was brought to my office last March with history of hoarseness, cough, choking at night, and increasing dyspnea. The examination was difficult, but I succeeded in seeing the larynx apparently filled with a cauliflower-like growth. I sent her to the hospital, expecting to do tracheotomy at once. On arriving at the hospital the child began to cry, became cyanotic, stopped breathing, and before the tracheotomy, done by an interne, was completed the child was dead. [The larynx removed from the tracheal wound was passed around.] The growth springs from the true and false cords, and nearly fills the glottis opening. A deep inspiratory effort wedged the growth in the chink of the glottis, asphyxiating the child.

In 1897, Rosenberg collected and published 231 cases. Since that time I have been able to collect 16 cases, thus with my own making a total of 252. Of these, 114 were boys, 100 girls, and in 38 the sex is not mentioned. Fourteen of the cases were under two years of age; 57 between two and four years; 38 between four and six; 19 between six and eight; 39 between eight and thirteen. In 15 cases the age was not stated.

Papilloma of the larynx may be congenital, although I consider this a rare form. It may develop early in life, following an attack of one of the acute exanthemata. In one of my cases it appears to have been caused by an acute laryngitis. Lennox Browne thinks that adenoids and enlarged tonsils may act as etiologic factors, although in none of my cases were they present.

When occurring in the first few years of child life, the growth is generally multiple, pale grey-white in appearance, and springs especially from the true and false cords, although the whole laryngeal surface may be involved. Later, it may be single or lobulated, and generally makes its appearance in the anterior half of the larynx, developing on the true cords.

The clinical picture in a well-developed case is characteristic: a rough hoarse voice, or loss of voice, cough harsh and annoying, a distressing inspiratory dyspnea with retracted chest walls and shallow breathing. Laryngeal spasm is not an infrequent symptom, and a rather free mucous expectoration is generally present. The diagnosis can be made almost from the clinical history and the general appearance of the child; a positive diagnosis by means of the laryngeal mirror will often try the patience of the most expert laryngologist.

Autoscopy I found of great value in one of my cases. Frequent examination of the sputa will disclose particles of the growth which have become detached and are expectorated.

Treatment of this class of cases may be divided into two forms: 1. Where the dyspnea is not marked, rest in bed, absolute rest of the larynx and a general tonic may be tried. Various local applications may be used. In my hands a 5 per cent. solution of salicylic acid in alcohol, with the addition of 3 per cent. of resorcin, has proved of benefit. 2. Operative treatment may be of three kinds: laryngotomy, tracheotomy with or without intralaryngeal procedures, and intralaryngeal operations.

In order to compare the value of these various methods I have, as Rosenberg did in his article on this subject, divided the operative cases in three groups according as they were treated by laryngotomy, tracheotomy or intralaryngeal means. Some of the cases are difficult to classify, as two or more of the above methods were tried. Rosenberg reports 88 cases treated by laryngotomy with the following results: 17 cases died from various causes; diphtheria, bronchitis, pneumonia, or suffocation from recurrence; in 5 cases the result is not reported; 34 cases recurred, in 6 with voice affected, in 1 with breathing disturbed, 1 with necrosis of the thyroid cartilage, 2 with fistula, and in 3 the cure was only temporary.

Bruns, in a paper published in 1878, comes to about the same conclusion. In 21 cases collected by me since Rosenberg's paper was published, 5 were treated by laryngotomy, 1 died, 2 cases were cured, 1 recurred, and 1 is in doubt. Roughly speaking, of all these cases 40 per cent. were cured, 20 per cent. died, and recurrence occurred in about 40 per cent. Of the total 252 cases collected, 43 cases were treated by tracheotomy with the following results: 21 cases, or 49 per cent., were cured, 3 cases, or 7 per cent., recurred, 12 cases, or 28 per cent., died, and 6 cases, or 14 per cent., were in doubt.

In the third class I have placed only those cases actually treated by intralaryngeal methods. Of the 21 cases collected by me, 6 cases were handled by this method, 4 were cured, 1 recurred, and 1 case is doubtful. Rosenberg's table shows the following results: Out of 48 cases, 3 died; in 7 the result was doubtful, 6 improved, in 4 temporary cure and in 27 cure absolute.

Of the methods employed in the removal of these growths, I shall have little to say. Personally I used Krouse's small pincet-forceps and the snare, and I think I have had good results from following up the intralaryngeal operations with the daily application of a 5 per cent. solution of salicylic acid in alcohol. I should like to offer the following deductions:

1. That papilloma of the larynx is, especially in this country, a rare disease.
2. In a number of cases they undergo spontaneous cure.
3. Intralaryngeal methods should always be tried first, unless dyspnea is pronounced, when tracheotomy should be done at once.
4. After tracheotomy, intralaryngeal methods should be tried.
5. Patient should wear a tube for six months after the growth has disappeared.
6. Thyrotomy should be considered only as a last resort.

103 State Street.

UNUSUAL PAPILLOMATOUS GROWTH IN THE LARYNX.*

JOSEPH S. GIBB, M.D.
Professor of Diseases of the Throat and Nose, Philadelphia Policlinic, etc.
PHILADELPHIA.

The case which it is my privilege to present to the Section at this meeting was one of such unusual character as, in my judgment, to merit publication. While many of the features of the case are common to laryngeal growths, there is one characteristic, viz., its color, which makes it almost unique.

The opportunity afforded to study this case from an early period of its existence to the close was most fortunate, and I trust not unproductive of results, if not of immediate value to the patient, at least an addition to our store of knowledge in the field of laryngeal growths. The history as taken from the records is as follows:

John D., aged 52 years, a laboring man, always enjoyed good health until present illness; family history is good. No tuberculosis or cancer existed in family so far as he knows. He had a chancre when a young man, but has no recollection of secondary manifestations.

The first symptoms of the present illness began in the winter of 1896, and consisted of a slight hoarseness and tire after talking. Soon a slight cough appeared and he began to experience some impediment to free respiration, at first only manifest on exertion, e.g., ascending a flight of stairs. These were the symptoms of which he complained when he first presented himself. Examination revealed the following conditions: Pharynx injected and exceedingly sensitive, requiring the use of a local anesthetic to tolerate the presence of a mirror. The mucous membrane of the larynx is red and the cords injected; approximation of the cords perfect. A pearly-white deposit extends from the base of the left arytenoid body on the lateral wall of the larynx down to, but not involving, the true cord of this side. This whitish deposit seemed to consist of an innumerable number of fine filaments closely packed together, in mass presenting an appearance not unlike that of mycosis in the pharynx. During the examination a peculiarly unpleasant odor is noticed. This deposit or exudate is firmly fixed to the membrane from which it springs, and resists all attempts to brush it away. There is a slight edema of the tissues immediately surrounding the deposit, but there is very little encroachment upon the lumen of the laryngeal cavity.

Acting on the suspicion that the peculiar condition was syphilitic in its nature, increasing doses of a sat. sol. of iodid of potash were given until gtt. xl. t.i.d. were tolerated, and this was continued for a month or more. The only effect of this treatment was to improve both the quality of the voice and the dyspneic symptoms. The only change noticeable in the larynx was a diminution in the edema. So far as the exudate was concerned, three months from the time the iodids were commenced, in which time they had been taken almost continuously, there was absolutely no change, either in character or extent.

During the summer of 1897 I saw very little of the patient, and at these occasional visits no change could be detected in the laryngologic appearance. Early in the fall of this year the iodids were discontinued and simple tonics were prescribed. During the winter of 1897 and 1898 the patient was seen regularly, at least once, and sometimes twice, weekly. Very slight changes were noticeable in the larynx and the general symptoms varied. At times he seemed weak and nervous; at others he would grow stronger, even taking up work at the navy yard during the recent war with Spain. The only symptom of note to record during the period from October till May was a slowly increasing dyspnea, especially manifest on exertion or after an examination by the laryngeal mirror, a slight cough, very harsh and smothering in character and increasing hoarseness.

During the summer, from June till September, I saw very little of the patient. The early part of this period he was, as above stated, engaged at the navy yard and had no time for treatment; the latter portion I was out of the city. I again saw him the early part of September, 1898, and noted a very marked change in him, both as to his general condition and the appearances of his larynx. The breathing had become noticeably oppressed and noisy; there were frequent, short, sharp, smothered coughs and he seemed much distressed. He stated that he had not been able to sleep for weeks, because of the great difficulty in breathing; appetite had failed and he had become somewhat emaciated. In the larynx it was seen the growth had increased, both in extent and bulk; the entire left side of the larynx was covered and a portion of the right. The lumen of the larynx was encroached upon to such an extent that only a very small section of the anterior edge of the right cord could be seen. The general appearance of the deposit remained the same, viz., the glistening, pearly-white color; the odor had increased and was distinctly fetid. His condition at this time was so serious he was urged upon to come into the hospital so that he might be watched and prompt relief given. However, he remained away for three weeks, and when he again presented himself his symptoms were so urgent as to require no persuasion to obtain his consent to enter the hospital. Indeed, so eager was he to obtain relief from his great distress that he was perfectly willing to submit to anything.

He was admitted to the Episcopal Hospital the evening of October 7. So alarming were his symptoms that I felt at first his trachea should be opened at once; but, recognizing the disadvantage of doing the low operation by artificial light and also during the distressing paroxysms of dyspnea, I decided to wait a short time. The urgency of the symptoms passed over in a little while and the operation was fixed for the next afternoon.

The low tracheotomy was done the afternoon of October 8. No general anesthetics were permissible, hence a 4 per cent. solution of eucain was injected into the skin along the line of the proposed incision; this controlled the pain perfectly. The trachea was unusually short and deeply situated, so that some little time was consumed in reaching it. In cleansing the trachea of loose connective tissue previous to incising, some of the deep veins were torn and considerable bleeding resulted. Unfortunately, at this time the patient was seized with an unusually severe paroxysm of dyspnea, and for a few moments it looked rather hopeless. Happily, time was allowed to catch up and tie the bleeding vessels and rapidly open the trachea. This at once relieved all the urgency of the symptoms.

---

*Presented to the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The ordinary tracheal tubes were all too long in the curved portion, so that great difficulty was experienced in having them retained. After using two, a third was found which seemed to hold in position. In consequence of the difficulty with the tubes, it was deemed expedient to take a stitch on either side of the incision in the trachea with a short silk ligature, so that the trachea could be separated and breathing sustained in the event of the tube slipping out. The following afternoon, on my visit to the hospital, the tube was in the wound and the patient was breathing through the slit in the trachea. After some difficulty the tube was replaced and gave no further trouble. On the third day the patient developed a purulent discharge from tube, with high temperature, and died suddenly at noon on the fourth day.

Post-mortem.—The tongue, larynx and trachea down to the bifurcation with adjacent tissues were removed for examination. The length of the larynx and trachea from the top of the thyroid cartilage to the bifurcations is a trifle over 5 inches. From the top of the thyroid to the tracheal wound is 3 inches. At the position of the incision in the trachea, which when the parts were *in situ* was a little above the suprasternal notch, the trachea bends to a right-angle; this angular portion is about 1½ inches in length before its ultimate division. The wound in the trachea is ragged and irregular.

The larynx and trachea were split open in the median line, commencing above the suprathyroid notch and extending downward to and joining the incision in the trachea. The cartilages were completely ossified, requiring the use of the saw for their division.

Looking into the larynx from above, both arytenoid cartilages are thickened and indurated, the right to a greater degree than the left. The new growth almost entirely covers and extends above the left arytenoid; on the right the growth extends to nearly the top of the arytenoid, leaving about ¼ inch of the cartilage free though much indurated. The lumen of the larynx is encroached upon to such an extent as to barely admit of a crow's quill. The epiglottis and all the extralaryngeal tissues are entirely free from the new growth. After separating the divided thyroid cartilages and trachea, the entire larynx seems to be filled with the new growth, which almost entirely obliterates all landmarks. It extends from the apex of the arytenoid cartilage above and down to the lower border of the cricoid cartilage below. It is much more extensive on the left side and posterior wall of the larynx, absolutely obliterating all the normal tissues of the larynx. The right side is greatly infiltrated, the only recognizable tissues being the anterior third of the true and false cords and the lateral wall of the larynx lying between them. The growth is whitish in color, exceedingly soft and friable, breaking down upon the slightest touch of the probe. The trachea below the cricoid seems normal in appearance and presents nothing of interest.

The notes of the autopsy as to the other organs have been omitted, because they threw no light on the cause of death and were in most respects normal. In the light of a subsequent experience and from the symptoms presented just prior to death, I believe that cultures taken from the blood and internal organs would have shown the presence of streptococci in pure culture, and that the case was another instance of sepsis following operation in which intralaryngeal surgical work had been previously done. I am indebted to Dr. H. L. Williams for the following careful report of the microscopic appearance of the growth:

> A small piece of tissue about the size of a pea has been removed from a typical part of the surface of the growth, hardened in formalin, mounted and cut in celloidin and stained with hematoxylin eosin. On microscopic examination we note that the surface is exceedingly irregular and can be followed with difficulty, on account of the foldings and reduplications. Superficially we note a granular débris of necrotic tissue, mostly amorphous, with occasional leucocytes, small round cells and a few squamous epithelial cells caught in various portions. Beneath this we find an irregular horny zone of variable width, taking the diffuse eosin stain faintly, containing no nuclei and showing slight striation in lines parallel with the surface. As we pass beyond the horny zone the striations become more marked; flattened and spindle nuclei begin to appear between the striæ, and the outline of cells that have been flattened by pressure can be discerned. Proceeding still a little more deeply we come upon large, well-developed, typical stratified squamous epithelium with round, or oval, slightly granular nuclei, which take the hematoxylin stain very deeply. The cells at the bottom of this stratified epithelium are more compact and form a band from three to six cells deep. The outline of these cells is more regular and oval, while the nuclei are a trifle larger. The cells in the innermost layer are regular, closely packed, with dark granular nuclei, and come in immediate contact with the loose connective tissue beneath, which is seen extending in among the epithelial masses in long, slender finger-like processes. These finger-like processes appear to be the extension of slender papillæ from the underlying tissue, and are made up of a loose connective-tissue reticulum, and contain numerous small, thin-walled capillaries. They appear entirely normal. There is no apparent extension of epithelium into the connective tissue, and where the epithelium and connective tissue come in contact the epithelial cells are arranged with great regularity. In the outer horny zone there are many twists and quirls, somewhat necrotic, which appear like epithelial pearls.
>
> Summary: There has been a tremendous proliferation of stratified squamous epithelium, with a transformation of the superficial layer into keratin, and a tendency to the formation of epithelial pearls, while many slender connective-tissue papillæ project up among the epithelial layers from the underlying tissue. In giving a diagnosis we incline to consider it a benign papilloma, though the tremendous proliferation of squamous epithelium and the tendency to the formation of twists, which resemble epithelial pearls, is suspicious. Should malignancy be present, however, we should not hesitate to say that we believe it to be exceedingly slight and with no tendency to metastasis.

There are two features of this interesting case to which I wish to direct attention. The first is that of diagnosis. The symptoms presented at once direct attention to the larynx and indicate an obstructive lesion. Inspection of the larynx confirmed this suspicion and revealed a neoplasm. The peculiarities of this neoplasm is what attracts our attention, viz., a whitish, glistening excrescence limited to one side of the larynx, not materially interfering with the respiration—we are now considering the case in the early stages—not yet producing serious alteration in the voice, and unaccompanied by pain or cough.

By the process of exclusion we are enabled to determine what it is not, but the same process was not successful in revealing its true nature. Syphilis was first thought of, only to be rejected after a full trial of the therapeutic test. The location and many features of the case suggested the most common laryngeal growth, viz., papilloma, but it by no means answered to the usual appearance of growths of this nature. On several occasions pieces the size of a pea were removed and submitted to the pathologist for examination. Reports were received from two pathologists; while there is a difference in the phraseology of the two reports, they are as one in regarding it as of an essentially papillomatous character, though differing materially from the ordinary forms of growth in the larynx; this difference is manifest in the large number of horny epithelial cells in the outer layers. Mackenzie, in his early works on laryngeal growths, intimates that papillomatous growths may be of a whitish color, but lays no particular stress on growths of this character; I believe such an acute observer surely would have done so had he met with one. Lennox Browne also speaks of papillomatous growths as of whitish appearance, but with no separate mention. Bosworth says papillomata may be grayish-white in appearance.

It has been my privilege from time to time to present this patient to the section on Otology and Laryngology of the College of Physicians. There was much difference in the views of the Fellows as to the probable nature of the case, but there was unanimity as to its uniqueness. In a rather hasty review of the literature of laryngeal growths little has been gleaned to throw light on the present case. Gleitsmann's case, presented at the meeting of the American Laryngological Association in May, 1896, is similar to it in many particulars; unfortunately, he was not able to follow the case to its termination. The pathological examination of the growth in this case is strikingly similar to the case here presented; the diagnosis of the pathologist was papilloma durum, probably malignant and perhaps carcinomatous. The history of our case points strongly to malignancy, and yet the microscope at no time, either ante-mortem or post-mortem, shows positive evidence of its existence. Clinically it would seem that originally the growth was of a papillomatous character and had suddenly taken on malignancy, possibly because of intralaryngeal manipulations.

Note the apparent quiescence for a period of nearly two years, and then a sudden and remarkable activity and extension within a few months. Is not this the history of a benign growth taking on malignancy?

The second feature of the case to which I wish to direct attention may interest the anatomist rather than the laryngologist. The anomalous position of the trachea constitutes an unlooked for difficulty and seriously complicates tracheotomy. The trachea is found to bend abruptly backward at about the fourth ring; this leaves a space in which to open the trachea, between the lower border of the thyroid cartilage and the fourth tracheal ring, a distance in the present case of a trifle over 1 inch. The greater portion of this space is occupied by the isthmus of the thyroid gland, which, under the disturbing circulatory changes of the laryngeal stenosis, is inordinately vascular and, hence, enlarged. Now, if one considers the undesirability of the high operation, in cases of laryngeal obstruction which practically rules this operation out, we are [illegible] the difficulty such an anomalous condition offers to the operator.

The peculiar anatomical position of the trachea clears up the difficulty encountered with the tube. At the fourth tracheal ring the trachea bends almost abruptly backward. The incision into the trachea is between the third and fourth rings, so that less than 1 inch of trachea is left between the incision and the abrupt bend. As the length of the segment in most tracheal tubes is a trifle over 1 inch, it is readily seen that the lower end of the tube impinged against the horizontal portion of the trachea and was thus forced out of the wound.

It is not the object of this paper to discuss the treatment, but the history of the case would scarcely be complete without some reference to the plan followed and to others that were contemplated. As an aid to diagnosis, pieces of the growth were removed; after having the pathologist report, an effort was made to clear the larynx. Much difficulty was experienced from the toughness of the base of the growth, which permitted us to remove only very small pieces at a sitting, and those were quickly reproduced, though always at the original site.

Intralaryngeal operations were abandoned after a thorough trial. The intention then was to do a preliminary tracheotomy and later split the thyroid cartilage and thoroughly clear the larynx. Months before the trachea was opened the advisability of thoroughly clearing the larynx by the extralaryngeal method was determined on. The patient, however, was very irregular in his attendance at this time and could not be made to appreciate the gravity of his situation.

At no time was the subject of laryngectomy considered, for the reason that clinically or microscopically there was no reason to suspect malignancy.

DISCUSSION ON PAPERS OF DRS. DICKERMAN AND GIBB.

Dr. J. Wright, New York City—I have been much interested in the last case because it helps to clear up in my mind one or two other cases that I have seen. The case of Dr. Gleitsmann, which was referred to by the last speaker, I had the pleasure of examining, and it presented a most singular appearance. It was pearly white with a papilliform appearance. The diagnosis was uncertain and is uncertain to this day. With the report made by Dr. Gibb in connection with the case I saw this winter, it seems to me that the three cases when put together clear up the nature of the trouble pretty well. The case I saw this winter, in connection with Dr. Dudley, was a case in which the growth appeared on the soft palate, and was the size of a quarter of a dollar, just back of a false plate the gentleman wore in his mouth. The patient was 72 years of age. The smoke passed directly from the end of the cigar, across the false plate and struck the soft palate without any interposition of the tissue in front. There this growth appeared. It was somewhat like a smoker's patch, and yet the extreme thickness of it seemed to rule that out. It was probably an eighth of an inch thick, with the edges sharp cut. At one side, dipping down into the tonsillar tissue were one or two islands. A piece was taken off and submitted to a pathologist for examination and an unhesitating diagnosis of carcinoma was made, which, from the age of the patient, and I confess somewhat from the appearance of the growth, made me agree with the diagnosis. The history extended over several years and there was no infiltration of the glands around it. The man was in too feeble a condition to justify the removal of the growth. On a later examination of the case I could not make out any malignant tissue. The cells which were rapidly proliferating were dropping into the lymph spaces, and these cells were not showing any evidence of malignancy. After consultation the growth was snared off with a cold wire snare, and in spite of our apprehensions the whole thing healed over and the patient inside of five days was relieved of all his symptoms and has remained well until this day. The condition is not a true papilloma, but a local hyperplasia of the tissue.

Dr. E. Fletcher Ingals, Chicago—Some ten or twelve years ago I saw a patient once or twice in consultation on account of a growth very much like that described in the paper. It was pearly white, firm to the sense of touch and had an appearance as if it were made up of columnar tissue, the ends of the columns having been cut off at the surface of the growth. This growth extended across one side of the larynx, above the cord, occupying the whole of the opening of the ventricle, and the lower part of the ventricular band. A portion of it was cut off and submitted to a skilled microscopist, who reported to me that it was a small-celled sarcoma. Within a few weeks tracheotomy became necessary, but the patient lived.

I was much interested in the excellent paper referring to laryngeal papillomata in young children. I recall a couple of cases of especial interest because of the treatment. One of these, a child ten or twelve years old, I saw before I was very adept in the use of instruments, and I had great difficulty getting hold of the growth, but finally I succeeded in pinching it hard. This growth was immediately below the cords and as large as a good-sized pea. I did not succeed in removing it that time, and the child did not return for a week or two, and then I found the growth had entirely disappeared. When I saw the patient some years afterward there had been no recurrence. In a little boy four or five years of age whom I treated about three years ago, I succeeded in examining the larynx very readily, but could not use the forceps. However, after rubbing the growth vigorously two or three times with a sponge, it entirely disappeared and there is no recurrence. I have tried the autoscope in children with laryngeal tumors two or three times and have been able to see the growth fairly well, but I have not had good results with it in operative measures. I had hoped we would get considerable assistance from it, especially with the children under an anesthetic, but I have not succeeded. I should like to know the experience of others with this instrument.

Dr. Norval H. Pierce, Chicago—In reference to Dr. Gibb's paper I wish to say that in my experience the laryngoscopic picture is not infrequently of only negative value in the diagnosis of laryngeal carcinoma. The appearance of the neoplasm, as well as its location and consistency, is often inconclusive. This is especially true of the first stage of its development. Later, we are oftener more or less able to positively identify the nature of the neoplasm by means of the laryngoscope alone. But the microscope will ever be the court of last resort, in this matter, as it is in so many others, for it is only by means of a structural examination of the tissue composing the growth that we may arrive at final conclusions, and even after such microscopic examination only positive results may be regarded as conclusive. It is generally admitted that the whitish-gray color, or refractive whitish surface, of a growth in the larynx is not by any means characteristic of malignancy; but it may be said on the other hand that many ulcerated carcinomata do possess this pearly-white color, which in a way is peculiar. In my opinion this coloring is due to a secretion which is derived from the juices of the malignant neoplasm. I have found that this coating is readily decomposed by peroxid of hydrogen. The surface of the tumor is then quite changed, being, instead of smooth, more or less granular, and, instead of pearly white, is pink or red or mottled. It has occurred to me that by means of this simple procedure we might differentiate in some cases between a malignant growth and benign hard papilloma, such, for instance, as Jurasz has reported, in which a vocal band was the seat of a diffuse chalk-colored, conical mass which was pronounced by several of his colleagues to be carcinomatous, but on careful microscopic examination after the death of the patient proved to be an absolutely benign hard papilloma. I repeat that if the peculiar juices of the carcinoma produce a somewhat characteristic coating on the surface of the growth as it occurs in the larynx, then the decomposing action of peroxid of hydrogen may be of diagnostic worth in aiding in the differentiation of laryngeal cancer from tumors which do not possess such juices.

Dr. W. B. Johnson, Paterson, N. J.—I think these cases of papilloma are of an interesting character, because so little seems to be accomplished by any form of treatment that is employed. Most of the cases that have been reported seem to have resulted in spontaneous cure without any definite knowledge of just what the cause was. I wish to say that I have used in such cases the application of formaldehyde, working on the theory that if absolute alcohol was good and was supposed to abstract water from the tissues, formaldehyde would be a better remedy. I am sorry to say that I can not report that the application of formaldehyde was successful. I have used intubation a number of times in preference to the tracheal canula. I have understood from others who under similar circumstances have used intubation, that it is a common occurrence for the papillomatous growth to grow over the top of the tube. Such has not been my experience. I am now treating a case with absolute alcohol spray used frequently, and am waiting patiently to see the result. One thing has suggested itself in the nature of an inquiry, and that is whether or not it is desirable to perform tracheotomy in cases of this character before dyspnea becomes very troublesome, for the purpose of allowing the parts complete rest.

Dr. Otto Joachim, New Orleans—I wish to bring to your notice a case in which the clinical history is very much the same as given by the Doctor. The symptom of recurrence was especially pronounced. The patient was a girl about six years old. The removal of the growth was not difficult, but recurrence was persistent, and it seemed the more I interfered with the tumor the more rapidly it grew. I finally made a laryngotomy, curetted the growth, and thoroughly cauterized it in the hope that this would terminate the condition. But this hope was fallacious. The treatment had extended over the greater part of the winter and spring, and when vacation time came on I left the patient in the hands of my assistant with instructions to use absolute alcohol locally. During my vacation this was used solely and continuously. I would not say that the use of absolute alcohol cured the patient, but at all events in the fall the growth had disappeared. I have seen the child frequently since, for a period of two years, and there has been no recurrence. There was some trouble in extubation and curing the fistula, which, however, was readily overcome.

Of the class of papilloma reported by Dr. Gibb, I have in mind three cases. The first one was not a case of my own. I had, however, an opportunity to make some microscopic sections of the growth and the report thereof was published in the *Archives of Otology* in 1887 or 1888. The second case was my own in which a diagnosis of horny papilloma was made, and it resembled the Doctor's case very closely. For two years the condition seemed to be in a quiescent state, but after that it became fulminant and rapidly fatal. In the third case the lesion was at the base of the tongue, very large and characteristic, about the size and shape of half an egg. The pathological condition agreed with the appearance of the case demonstrated by Dr. Gibb.

Dr. H. Stillson, Seattle—There seem to be papillomas and papillomata, and I have no doubt each member present says to himself, when the gentleman before him has finished speaking, "there are others." It seems to me our diagnosis of papilloma should go further into differentiation. I recall a case, which I suppose belongs to the classification given by Dr. Gibb and which has been mentioned as a hyperplasia by Dr. Wright, in an infant 12 months old. [illegible] growth was located on the frenum of the tongue, and [illegible] of an inch in diameter and somewh[illegible] what it was, nor do I know [illegible]ly ivory-whit[illegible] was [illegible] with it and [illegible] wh[illegible] I gave a place[illegible] as a mouth [illegible] it [illegible] in a few [illegible] ject. [illegible] had [illegible] few [illegible]

Dr. N. L. Wilson, Elizabeth, N. J.—In regard to the application of alcohol, I had a child 6 years of age whom I kept under my observation three years. After trying almost everything, after scraping the growth out twice, tracheotomizing, intubating, and having the intubation tube fall down into the trachea, I finally made up my mind to leave the child alone and find out what nature would do, and the result is that the child is well. I had made applications of alcohol by spraying it into the larynx. The growth sprang from beneath the right true cord. That made me think our friend had possibly overdrawn it when he said that alcohol would cure these cases. I have had cases, however, where the growth sprang from the larynx above the cord, and by making these topical applications, preferably with the canula, I have seen the growth shrink. One case now under treatment is much better than three months ago, although as yet the patient is not cured of her papilloma.

Dr. Taut—It appears to me the latest treatment of papilloma has been entirely overlooked. Two years ago I intubated for this difficulty and finally did a tracheotomy, and then the child drifted out of my hands and is now under the care of the "Christian Scientists," and if the gentlemen will visit the *Pan-American Congress* I shall be very glad to report the results.

Dr. Mackenzie—I have nothing to add to what is already known on the subject. I will simply say in connection with the dissolution of these growths by topical applications, that I believe one of the best of all topical applications, alcohol included, is sulphate of zinc. I have used for a great number of years a combination of sulphate of zinc and other things, but the chief ingredient is the sulphate in the proportion of two or three grains to the ounce. Years ago, when I was in Bellevue Hospital, I used a preparation consisting of 16 or 17 grains of sulphate of zinc, about 2 ounces of compound spirits of lavender and about 6 ounces of water, which acted very satisfactorily in shriveling up venereal warts on the genital organ. Since then I have used a modification of the solution on the throat in shriveling up small remnants left after operation on the larynx and also after operations for adenoid growths. I think in most of these cases it will be necessary to do a preliminary tracheotomy or laryngotomy. Much time is lost in the futile attempt to remove such growths through the natural passage. Especially in small children no time should be lost in performing preliminary tracheotomy, splitting the thyroid and removing the disease in its entirety. We can accomplish much more in that way than in picking away at the larynx over a considerable length of time. My experience agrees with that of others, that the growths often disappear spontaneously after preliminary tracheotomy. But that requires time, and if time is an element I think the best plan is to split the larynx and remove the growth at once in its entirety.

Dr. Emil Mayer—The case presented by Dr. Gleitsmann has been mentioned and I can add a little to the subsequent history. Dr. Gleitsmann said the last he understood was that the man was dead. A year after he made that statement the patient walked into my clinic and I inquired why he had given the impression that he was dead. He said the Professor was so interested as to come all the way out to one of the adjoining townships from New York City that he thought something dreadful was going to happen and he hid himself and his people reported that he was dead. I tried all manner of persuasion to get a portion of the growth for examination, but the patient disappeared and I do not know where he is. So, gentlemen, the statement that he was presumed to be dead may be refuted; at least he was living one year after the paper was read.

Dr. Gibb, closing the discussion—I am very glad to hear the report of so eminent a pathologist as Dr. Wright; it certainly adds weight to the opinion we had already given. I was likewise very much interested in Dr. Mayer's description of the termination of Dr. Gleitsmann's case. Anybody who reads how Dr. Gleitsmann chased this patient all over Brooklyn can appreciate the Doctor's remarks. I had hoped the discussion would take up, besides the pathological side of the question, the anatomical feature. At the meeting in Washington one of the members said tracheotomy sometimes is a formidable operation, and in this it was a very formidable operation because of the position of the trachea. The position of the trachea was an unforeseen difficulty, which one would not think of had he not seen a similar case.

THE RECIPROCAL RELATIONS BETWEEN CONSUMPTIVES AND SOCIETY.

S. G. BONNEY, A.M., M.D.
Professor of Medicine, University of Denver; Visiting Physician, St. Luke's Hospital.
DENVER, COLO.

No medical or economic problem at the present time can assume such a degree of importance on account of its almost universal application, and the degree of individual and state responsibility involved, as the prevention of pulmonary tuberculosis. This disease is known to affect approximately one-third of our population, and to constitute one-seventh of our annual deaths. Several millions of people in this country are now afflicted with a tubercular process, known to be communicable rather than hereditary. Practically, its transmission occurs, not so much from infected food-supply as from the existence of an almost ubiquitous agent disseminated by means of the sputa of infected individuals.

That the disease is thus communicable should not be understood to be so much the result of direct infectin from one person to another, after the manner of certain contagious diseases, but more because of the neglect to observe necessary precautions. There is thus permitted a wider distribution of the bacilli, whose continued presence in the home and in public places constitutes a source of danger to those rendered susceptible by occupation, manner of life, previous disease, inheritance and environment. Only to those especially predisposed is the disease communicable, and even to these, scarcely ever from a single exposure. Not only is the infection incremental in character, but rarely is the first infecting process known to exist after it is once acquired. More frequently is it the repeated infection which the individual resistance is finally unable to overcome without the recognized manifestations of the disease.

Despite these established truths, together with an actual diminution of the mortality-rate in recent years, wherever reliable statistics have been obtained, the fact remains that the welfare of the commonwealth is seriously threatened. The dark shadow of consumption still hovers over countless homes. There exists a foe in our very midst more dangerous than an invading host, and for whose complete subjection and the consequent safety of the people, there is required only a small fractional part of the energy and means that are expended in prosecuting a war of conquest, or in an imaginary effort to uphold national honor. To one whose sympathetic attention with reference to tuberculosis is constantly forced to the contemplation of the direful results of apathetic indifference and ignorance from some sources, and an immoderate professional attitude, with popular intolerance from others, there certainly remains much to be desired toward the practical solution of the tuberculosis problem.

Consumption is now recognized to be a distinctly preventable and largely curable disease, and hence should be prevented and cured when possible. Does there not exist, therefore, an imperative obligation upon the state to secure adequate protection for the community, and suitable provision for the care of those afflicted? This responsibility rests indirectly with the medical profession in its advisory capacity on matters pertaining to public health. The physician should be confronted with his obligation to consumptives no less than to society. Fortunately a wise and conservative regard for the needs of each class need inflict no hardship upon the other. Their interests are actually identical, and their relations should be reciprocal. That they are not so regarded at present is a reproach to the profession and should serve as an incentive to more active measures pertaining to the inspection and control of the disease, and to more duly considered methods of popular education. It is to be regretted that the advocacy of such extreme procedures as the isolation and segregation of consumptives, the placarding of houses, the necessary cremation of the dead, the enactment of laws governing marriage, and similar considerations have served only to inspire exaggerated feelings of alarm. It has been my observation that the public generally entertains no just conception of the manner in which the infection may be conveyed, and hence no appreciation of the comparatively slight danger of contagion under ordinary precautions. In like manner, it is quite unusual to meet consumptives who have received any competent instructions pertaining to the protection of the community. An unreasoning fear with a general prejudice on the one hand, is opposed on the other by a certain disregard for the rights of society, together with a natural resentment due to the humiliation imposed, and lack of moral support. It is apparent that the safety of the public must be exalted above the pride and sensitiveness of individuals, even though they constitute a large portion of the population. It is equally true that the burden of the consumptive should not be made harder to bear, and his chances to recover from a curable disease made less by reason of erroneous popular impressions and an inflamed public sentiment. Each class has its inviolable rights, and they should be made incontestable. It is incumbent upon the medical profession to recognize the claims each has upon the other, and in the capacity of arbiter to adjust apparent differences without injustice to either, and with broad sympathy for both.

What claims can be presented by each, and what measures can be instituted to satisfy them?

If pulmonary tuberculosis is preventable, the consumptive has a claim upon society by virtue of the very fact that he has become an innocent victim of the disease. He has been permitted to suffer a continued exposure to infection after having been subjected to such conditions of ventilation and hygiene as to bring about an increased susceptibility. Both the exposure and the lessened resistance have been to a great extent preventable. Who has jurisdiction to prevent, if not society? And if so, why is not the state morally responsible for its failure to do so?

It must be admitted that the consumptives of to-day, previous to the inception of the disease, had not been warned sufficiently of the practical dangers of infection, and instructed concerning intelligent measures of prophylaxis.

While this obligation on the part of society is now being fulfilled to some extent, it can not be said to apply to the great majority of those already afflicted.

Another claim of the consumptive upon society, and one reflecting directly upon the medical profession, is the distressing delay in securing accurate diagnosis. It is only with reference to early cases that consumption can be said to be a curable disease in the sense of its permanent arrest. Mistaken or delayed diagnosis at this time almost invariably associated with results of a most disastrous nature. The failure on the part of the medical profession to adequately appreciate the significance of rational symptoms, to recognize and interpret accurately the physical signs, has occasioned an annual sacrifice of thousands of human lives. The responsibility is more apparent when it is understood that too frequently the available data have been amply sufficient to warrant an early provisional diagnosis.

Referring to my observations previously published[1] on a series of 546 selected cases in private work, it is stated "that 388, or 71 per cent., arrive in Colorado with distinct evidence of tubercular infection in each lung." With reference to the duration of the disease before arrival, the total average period of delay from the time of definite onset of the disease, was a little over eighteen months, affording abundant opportunity for advanced pulmonary and constitutional impairment. "Is not the character of the cases sent to Colorado a striking commentary on the necessity of a more thorough appreciation of the principles capable of every-day application upon which to base early diagnosis?"

Has not the unfortunate victim of such delayed diagnosis a just claim upon the profession, and through it upon society, which in many states places no restrictions upon and enforces no qualifications for medical practice?

Another consideration to which the consumptive is entitled, is that of humanity. The pulmonary invalid is a human being and is not subjected to the same ultra-scientific principles that would be accorded the lower animals. He is above all entitled at the hands of the state to every energetic provision that may save or prolong life, and to every sympathetic attention that may help to alleviate suffering. Especially is this true of those who have not the means to subsist without work, independently of their more fortunate but often no more worthy fellows.

If the state is called on to provide institutions for her non-consumptive poor, who are frequently reduced to poverty through their own responsibility, and who are never to resume their functions as citizens, but are destined to forever remain as a burden to society, how much more should the state be obligated to provide similar institutions for those who have suffered, usually through no individual liability, who represent an entirely different class of citizenship, and who in many instances, with such a provision, can resume their duties and former positions in the community.

This claim of the consumptive poor is re-enforced by the added protection to accrue to society itself, through the control thus offered of those unable in their ordinary environment to observe sanitary precautions.

What are the claims of society with reference to the consumptive?

Inasmuch as the invalid, in the absence of certain precautions incident to his daily life, is a direct source of contagion, and therefore a menace to his family and the public, and whereas, a strict conformity to prescribed instructions actually prevents him from becoming an element of danger, it becomes incontrovertible that society has the right to expect and demand of the consumptive the most rigid observance of sanitary rules, the most hearty co-operation and willing submission in the way of conservative municipal control. Popular prejudice and drastic legislative measures may inflict added burdens upon the consumptive, but the one purpose to be attained, public protection, will have failed of accomplishment if there is not secured his individual desire to faithfully perform his part. It is the invalid himself to whom our efforts must be addressed, and these in the form of instructive and persuasive appeals. With the acknowledgment of its own obligations, society justly will receive a recognition of its claim upon the consumptive. Through an active educational propaganda, these claims will meet with a ready response, the exception being only with those who are very ignorant or vicious, and for whom special detention institutions may be erected for the public weal.

---

[1] Medical News, Sept. 30, 1899.

As to the various means that may be employed to satisfy the joint claims of consumptives and society, it is primarily essential that there should be a uniformity of method in the several parts of the country. A concerted plan of action under national authority would be most effective.

A distinct bureau of public health, elaborating upon the excellent work now done by the Marine-Hospital Corps, having an advisory jurisdiction over state and county societies, and exercising immediate authority over all officers of public health, would do much along the lines of preventive medicine, if such could be made practicable without infringement upon the rights of states, and without the taint of national politics. It is to be feared that in some instances personal political ambition has biased the health authorities to an undue enthusiasm in the administration of public office. For such responsible positions men should not be selected as a result of political preferment, but should be chosen by their fellows on account of their peculiar adaptability to faithfully execute such labors, for which greater compensation should be rendered, commensurate with the arduous responsibilities involved.

The campaign of education and municipal control should include at once the compulsory notification and registration of all cases of pulmonary tuberculosis. This does not imply placarding of houses or apartments, isolation, or other personal humiliation, but furnishes an opportunity for more thorough inspection and supervision. Interference with social aspects and business pursuits is uncalled for. Quarantine and segregation are altogether impracticable. The family ties of several millions of people are not easily disrupted. Segregation is alone feasible and desirable in the case of the consumptive poor. It should be made clear that notification and registration does not carry with it the contemplation of interference with personal rights, unless rendered necessary by the repeated and intentional infractions of prescribed regulations. Notification should be made obligatory upon patient, physician and householder, and failure to comply should be punishable by fine. Periodical disinfection of apartments should be made under the supervision of the health departments, and always done following the death of the patient. It should be no hardship for the consumptive to be in a position to receive competent instruction from some responsible source, either directly or through the attending physician. By this means, added protection is accorded to himself and family as well as to the community.

The methods of instruction directed to the consumptive with his family, and to the general public should be to impart an appreciation of his obligations to society, and to secure his active, unremitting coöperation. He should be supplied with carefully prepared circular information explaining the dangers of infection and re-infection, describing in detail all necessary preventive measures, with an emphatic demand for their observance. It is of vital importance that all official information afforded the general public through any channel whatever should be essentially of a reassuring nature, although not minimizing the possible dangers resulting from the presence of the careless consumptive. Through the medium of public documents for general free distribution, the newspapers and public addresses, the public should be informed concerning the comparatively few methods of possible infection. It should be made clear that the infection can be thus conveyed only through gross violation of the simplest precautionary measures, and that a due regard for such sanitary rules afford protection from direct infection despite intimate and protracted association. It should be explained that the infection is exceedingly slow and rarely results from a single exposure. It should be emphasized that unless the soil is rendered receptive to the bacillus by lessened individual resistance, infection is unlikely, despite more or less exposure. Apropos of this, attention should be called to the necessity of greater individual care concerning mode of life, occupation and environment. The hygiene of the home should be discussed at some length, with especial reference to ventilation and sunlight.

In addition to these more direct methods of instruction through the medium of the profession, there should also be instituted a degree of governmental or municipal supervision of the construction of public buildings, tenement houses, factories, commercial establishments and conveyances. Ordinances should be enacted and enforced prohibiting expectoration on the sidewalks, crossings, or in any public place where people walk. Offenders should be punished for repeated violation of this. The objection to the occasional expectoration upon the street or in the gutter, disgusting though it be, does not appear of great practical significance, as far as actual danger is concerned, in view of the more direct exposure to sunlight, the frequent sprinkling and the fact of the bacilli not being kept in circulation and carried to the home by the sweeping skirt.

The spectacle of the use of the expectoration flask is revolting and hardly necessary. Small napkins of cheese-cloth held over the mouth in the act of coughing, to serve as a receptacle for sputum, and subsequently deposited in bags made of oil-silk, oil-muslin, or rubber, capable of disinfection, are infinitely more satisfactory from every standpoint.

Of surpassing importance is the matter of sanatorium provision for the various classes in appropriate climates. I can but take vigorous issue with those who fain would regard the influence of climate upon pulmonary tuberculosis as a "fetish of the past," now replaced by sanatorium régime. It is a matter of record that the satisfactory results obtained in the few institutions of this kind, without the most favorable climatic attributes, is largely due to the fact that only incipient cases are admitted. Disclaiming any desire to detract from the intrinsic worth of such institutions, I am forced nevertheless to make the query, "Have we evidence to substantiate the claim that the improvement in each case has been invariably due to the sanatorium itself?" Would not the same régime observed outside the institution have been attended with results almost, if not quite, as good? It is well known that a considerable number of incipient cases get well in the less favorable climates even despite unfortunate conditions and environment, in the absence of rational measures, and often without the knowledge of the tubercular character of the affection.

It has been my experience in Colorado to observe patients presenting a history such as would be applicable to these cases, and showing after the lapse of several years, a record of a fresh infection. Upon arrival, in addition to the recent tubercular process, evidence is occasionally found, upon physical examination, to justify the theory of a previous infection, subsequently arrested.

I feel warranted, therefore, in asking if the heralded results of sanatorium treatment in unfavorable climates in incipient cases are not due in some measure to the simple relief from work, changed surroundings and detailed instructions, at least a portion of which could have been secured in many cases by the same competent medical adviser outside his institution. I have chanced to meet several such sanatorium cases that have experienced a return of their trouble, and have sought climatic improvement as more advanced cases after a disastrous period of delay. I am impressed that the sanatorium life for consumptives is of value largely by virtue of the enforced regimen, which appears to be practicable without the aid of the institution, especially among the better classes. There can be no question, however, of the improved facilities for the management of the consumptive poor, and even those less embarrassed financially, in properly conducted sanatoria in any climate. This, however, should not be construed as constituting an argument against the greatly increased benefits to be derived from appropriate climatic influences. While local sanatorium accommodation should be made for the consumptive poor in every state, I would strongly advocate the construction of special institutions in various regions applicable to the several stages and complications of the disease. Such sanatoria should be adapted to the special needs of the particular class for which they are erected, opportunity for outdoor employment being offered in some to those whose physical condition will permit, as a means of defraying expense. A number of these institutions could be under the control of one or several states jointly, some under federal supervision, and still others directed and maintained by the several benevolent orders and societies. It is for those in more or less financial distress that sanatoria are specially demanded. There is at present no provision for the enormous class of consumptive poor, who, unable to work, and rejected in turn by all the charitable hospitals, appeal despairingly for relief. For these there is now no alternative but death.

In these times of unexampled prosperity, have not our impoverished consumptives, with this preventable and curable disease, a claim upon society that can no longer be ignored. It is not a time for pedantic assertions concerning marriage laws for the pulmonary invalid, the undesirability of tuberculous offspring and the care of the consumptive dead, etc., but a practical application for the benefit of the living of those humanitarian instincts ever ready to respond to the call for help. A determined public effort toward the arrest and amelioration of the disease in those unable to help themselves would also be attended by prophylactic results of a most satisfactory nature.

THE PRESENT secretary of the navy of Portugal, Dr. Tiexura de Sauza, is a physician.

THE SERUMS IN TUBERCULOSIS.*

PAUL PAQUIN, M.D.
ASHEVILLE, N.C.

TOXINS IN THE TREATMENT OF TUBERCULOSIS.

The remedial use of these poisons has practically been abandoned. Inaugurated by Koch, who saw good results in the use of tuberculin in certain cases of lupus, his incomplete investigations were pushed into publicity prematurely by over-sanguine officialism in Germany, and great was the general disappointment and the damage to Koch's well-earned reputation when our hopes vanished.

Later, Klebs preconized another form of tuberculin called "antithesine." Much was claimed for this so-called modified form of Koch's original tuberculin, and it was used for a while as a remedy for tuberculosis. It did not add luster to the already high reputation of this scientist, and to-day it is not in general use.

Then came Dr. Von Ruck's antithesin. Von Ruck has for a few years published great promises about this agent, which he has named "watery extract" of the products of the bacillus of tuberculosis, and of which different varieties are offered. It is urged that this preparation is free from certain poisonous elements existing in other tuberculins, by virtue of which, irritation and fever are produced.

These toxins are each one form or another of tuberculin, the poisonous products of the germs and their culture, and all are modifications of Koch's original agent, repudiated by himself and his followers as a therapeutic measure. Finally, in the last three or four years, Koch recommended still another tuberculin which he termed "tuberculin residuum," T. R. for abbreviation. It consisted of a product including the natural poisonous liquid of a broth culture of the germ of tuberculosis and the toxins of the structure of these parasites, extracted by a process of pulverization, mashing (?), centrifugalization, filtering, etc. The revived hopes it created by the magic of Koch's name passed into oblivion within a few months of the first report.

Such are the toxins of the tubercle bacillus of which we have records as medicinal treatments for the "white plague." Only one remains in evidence, namely, Von Ruck's watery extract, for which he and some of his followers have established seemingly reliable, but in fact dangerously misleading, records, for their chief reports were made at the health resorts of North Carolina and Colorado, where equally good results have been obtained by numerous physicians by good management and climate alone.

The merit of all these products, if indeed they have any, which I do not deny to a certain degree and under proper circumstances, depends wholly on the poisons which they contain. If all the poisons are abstracted or neutralized, the product becomes bland, it becomes as water. If only certain kinds of poisons are abstracted it becomes modified in its toxic properties to that extent; and to that extent also it is depreciated in the power to produce reaction. Now, the toxin of an infectious disease is utilizable as a therapeutic measure only to the degree that it may, by reaction of the system, produce a measure of immunity more or less complete. That means vaccination. Vaccination is not a curative, but a preventive measure, and consequently should be applied before the existence of the disease against which it is desired to vaccinate. We do not vaccinate against smallpox after but before the disease has invaded the system. Hence, the claims of the tuberculin adepts, that any kind of tuberculin is specifically curative, is not sustained by any scientific fact from disinterested sources. Its application must be limited to the very early cases in which the lesions are slight and the activity of the germs localized. Then it may be possible for tuberculin to establish a certain degree of immunity before the localized infection has taken on too serious activity.

---

* Presented in a Symposium on Tuberculosis, to the Section on Hygiene and Sanitary Science, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The peculiarly effective action attributed to watery extract can be of no other character save that depending on a graded degree of blandness, or virulence if you please, affording a gradual exhalation of effects with less irritation, than by the administration of strong toxins at once.

We see from these data that none of the tuberculins have any general established merits as remedial agents against tuberculosis. Nor have we any reliable indications whatever that they may be used safely to advantage as vaccinating agents in human beings in the sense underlying anti-smallpox vaccination. In my judgment their only meritorious sphere so far is the field of diagnosis in cattle, which you kill if you find infected. I must differ from the views that it should be used as a means of diagnosis in human beings suspected of being afflicted with tuberculosis, but showing no sure sign of it. With the light before us, we are not justified in provoking in a human body a fever which may ignite the tubercular spark which nature was in her own way smothering, with 50 per cent. of chances in her favor of success without the physician's interference. It would be better to treat such cases as pretuberculous, and not arouse any inflammatory conditions anywhere, far less in the infectious foci.

SERUM IN TUBERCULOSIS.

The idea of serotherapy in general may be traced back to Maurice Reynaud's observation prior to 1888, when he discovered that the serum of vaccinated heifers at the seventh or eighth day conferred immunity to vaccinia in susceptible subjects. Next came Richet and Hericourt, in 1888, who by their experiments with a pyoseptic germ in animals, pointed to the probability of certain virtues in serum. Afterward, Behring established that serum was not an inert matter, but rather, in some sense, a vehicle carrying a vital principle, to which it was but natural to at once attribute an important rôle in the resistance of individuals to infections. This staggered the Metchnikoff theory of phagocytosis, and for a time lent ammunition to its adversaries. But far from annihilating it, it explained its philosophy much more clearly than its founder and his followers had succeeded in doing before. It pointed to the means by which the leucocytes destroy germs and their poisons in the system. Afterward Behring and Kitasato clearly demonstrated the effect of the immunized blood-serum against tetanus on one hand and diphtheria on the other. These investigations were sustained by Roux, of Paris, and others. Every one is familiar with these discoveries. I only need allude to them as a historical step in serotherapy in general.

Not very long after Koch's failure with tuberculin, Maragliano, of Italy, doubtless stimulated by others in France, notably Richet, who had experimented with serum of the dog and goat in consumption, recommended the natural serum of the ass in the treatment of consumption, on the ground that that animal is comparatively immune to this disease.

All these sera failed to produce permanent or even semi-constant beneficial results. In 1894, the writer experimented, in St. Louis, with horses, which he immunized against tuberculosis by graded and persistent injections of tuberculin, germ structure poisons (long before Koch preconized his tuberculin T. R., which is practically the substance here given), desiccated germs, and finally by the injection of pure virulent cultures of the bacilli administered both into the circulation and connective tissue. This was the first effort made in any country to produce immunized serum to use against consumption. The product was used in 1894 and 1895 in the St. Louis City Hospital in a series of tubercular patients of various kinds and degrees of involvement. The first report about them was made in the spring of 1895.

To comprehend the limits and possibilities and fallacies of serotherapy in tuberculosis, permit me to specify the properties of serum and then to explain them briefly.

1. Serum contains toward some microbes a positive bacterial power, which is destroyed at less than 60 C., whilst against others it does not.

2. It may be rendered capable of acting as a preventive, that is, immunizing agent, by a different element than that responsible for bacterial power, because the immunizing virtue resists a temperature of 70 C., i. e., less than the bactericidal power does.

3. It contains an antitoxic property which was long confounded, and is still in a measure, with the other properties of serum by many, particularly the superficial investigators and biased speculators, and the practitioners who have financial interests in confusing the professional mind by maintaining an error to sell their wares, which are not wanting in variety and incongruity in the therapeutics of tuberculosis. It is here that the advocates of the tuberculin or extracts of tuberculin under any name find a motive for their pleas.

4. Finally, as a therapeutic agent, not of serum itself, but of the figured elements of the blood from which it is obtained, there exists in serum the action of the leucocytes on soluble poisons. Let us understand these properties.

Bactericidal Power of Serum.—It is natural, not acquired. This influence is exerted on the micro-organisms themselves, and not on the system in which they live. This was demonstrated, in 1888, by Behring in natural rat-serum with regard to the anthrax bacillus. Speaking of serum pure and simple, twenty-four hours of contact prevents cultures of mixtures of serum and certain germs. But it is not a preponderant influence. It is not constant. In the white rat, refractory to anthrax, the bactericidal power of the serum may be only coincidental; on the other hand, while we find cases in which immunity exists in connection with a germicidal power of the serum, we find the contrary in other animals. For instance, the serum of rabbit's blood is bactericidal for the germ of anthrax, yet this animal is remarkably susceptible to that disease.

Again, the dog's blood is not germicidal to the anthrax germ, and yet that animal is comparatively immune to anthrax. So we conclude that the germicidal power of serum is not a preponderant factor in producing immunity, nor is it generally to be counted on as a constant or general therapeutic agent. Nor is this virtue of great importance as a resisting power against disease.

Note that this power is destroyed at 55 to 60 C. without injury to the other properties. Consequently this faculty is a biologic one, the nature of which remains undetermined. The theories of Hankin and others that they are alexins, globulins, etc., have not been proved. But it does not resemble the globulicidal power.

Preventive and Curative Faculty of Serum.—First it is produced by the early action of disease elements. However, it may have a natural existence to a certain degree. As stated, this property was and is confounded with the antitoxin effect. Yet it is altogether different. Definite reliable antitoxic powers have been established satisfactorily only in the serum for tetanus and diphtheria. The preventive power is much more general than the antitoxic and far less specific, but it is comprehensive, valuable, and therefore useful in therapeutics. Researches on cholera, pneumonia, typhoid fever, etc., have demonstrated experimentally that in all these afflictions the serum of animals vaccinated against them protects a new organism, but remains without effect on the culture products of the causative germ. Thus, animals become immune, temporarily at least, to these maladies, without the action of antitoxins. How is it done? By cell stimulation, increasing phagocytic power and cellular nutrition. Metchnikoff demonstrated that, in hog cholera for instance, and others have done just the same with pneumonia, vaccinated animals resist the disease; that sick animals are cured by serum and yet no antitoxic power measurable by Behring's law exists. It is here, in this virtue, that we find assistance in the treatment of tuberculosis. It is a strong stimulation of the organic resistance. Metchnikoff and others have seen a stimulation by the preventive faculty sufficient to produce a large increase of leucocytes in the blood or about the locality of local lesions. I have observed this phenomenon locally in tuberculosis in man and beast. Diphtheria antitoxin, on the contrary, may reduce the leucocytes. It is also stated by Srabritchensky that the zymotic action of the leucocytes is augmented.

The Antitoxic Property.—It is artificial, not natural. Büchner thought this faculty the same as the preventive faculty. It is not, for it is not destroyed by heat in twenty-five minutes at say 65 C., which kills the immunizing faculty mentioned before, for pneumonia, cholera, typhoid fever, etc. By experiments, Behring and Kitasato arrived at a means of calculating the ratio of antitoxin necessary per weight of animals injected with diphtheria or tetanus toxins, thus measuring precisely the quantity of antitoxin necessary to neutralize the power of a given quantity of toxins which, without the antitoxin would prove fatal. Hence the idea that the antitoxic power is due to a chemical agent acting directly on the toxin of the germ, which it does not kill. This task remains for other phenomena, chiefly phagocytes. The recent theory of Behring that the antitoxins are due to the so-called "side-chain" atoms of the proteids which are necessary to functional activity, and which are increased by the action of bacterial poisons and then circulate in the blood as antitoxin, is most fascinating and supports the opinion of chemical antagonism. Thus we see that the germicidal, defensive and the antitoxic powers are different faculties. The first is natural and inconstant, but kills some germs; the next influences the organism in which the germs develop and may arrest microbial growth that way; the last or antitoxin power exerts itself on the toxic products only.

Action of Leucocytes on Soluble Poisons.—This tentative theory is not so well established as those first mentioned. It is reasoned from the experiments of Chatendy and Metchnikoff. These show that the poisonous action of germ poisons, vegetable toxalbumins or a serpent venom, are absolutely comparable to the action of infections, i. e., they produce hypoleucocytosis if the animal is sensitive or gravely ill; hypercytosis in cases of resistance. The theory is that the phagocytes by selective affinity absorb the poisons, as the cells absorb stains for instance, and that in those cells these poisons are destroyed by a cellular diastase on the principle that pepsin and trypsin can destroy the toxin of diphtheria and tetanus. Such are the biologic properties of serum.

The physiologic properties consist of influences apart from the infections, and are of utmost importance, though meagerly considered or ignored by the practitioner.

1. There is the globulicidal power of the serum, which consists of the faculty of the blood-serum of one animal to destroy the red blood-cells of another. This occurs as well out of the organism as in the circulation. This property, however dangerous in therapeutics, can be destroyed by the proper laboratory processes too often neglected, but which should be insisted on. It also suggests that we should not introduce therapeutic sera directly into the circulation.

2. The coagulating power of the serum means that the animal-serum introduced in the blood of another may produce coagulation by the precipitation of febrin. Richet pointed out this danger, and I have seen it realized. But this property also may be destroyed by laboratory processes.

3. The toxic power of the serum may produce symptoms of intoxication, with myosis, temperature, dyspnea and eventually convulsions. This property is attributed by Mr. Bosc to albuminoid substances. I am convinced, however, that this is not the only source of this unfortunate faculty. It may come from numerous causes dependent on ill health of, on digestive troubles in, the animal supplying the blood, thus creating soluble poisons which circulate in the plasma. It may come from the poisonous waste of metabolism, when an animal is bled and the blood is loaded with unknown quantities of toxic substances in process of transformation or on their way to excretory channels.

All of these are important questions, which the practitioners should insist must have been properly respected by the producer of the sera of any kind that he uses—a condition that I know some producers wholly neglect.

Is the applicability of serum in tuberculosis warranted by the general facts established of the serum properties? If so, when, how and in what cases? What serum should we use? What may we expect?

To the first question I answer, yes. Serum is applicable as a remedial measure. It has, by virtue of some of the effects mentioned above, curative properties. I point with gratification to the recovery of 29 cases of pulmonary, throat, bone, joint, kidney and testicle tuberculosis that recovered under my observation and with serum treatment exclusively in most of them, from the states of Missouri, Louisiana, Indiana, Illinois, Ohio, Pennsylvania and Iowa. These patients were treated, with few exceptions, in the city of St. Louis, and all of them under climatic influences fatal to consumptives. I have kept track of most of them and they are in the enjoyment of sufficiently good health to-day, four or five years after their treatment, to keep at their various occupations.

When and how to use serum are questions that belong to practice.

What sera should be used? That is a very important point, as I have just stated. As you have seen, serum naturally possesses dangerous properties that must be eliminated. Some sera for various diseases are not thus purified. I have tested many in which the poisonous properties are thus retained.

Can serum be depended on as an agent to produce lasting immunity against tuberculosis? In the first place, I believe that immunity against this disease is probably always relative and limited as to degree and duration. But it is measurable to a degree, and to that extent serum may be useful. But, although I have long experimented with, used and tried to perfect serum, I am still of the opinion from which I have never departed, assertions to the contrary notwithstanding, that serum is not yet to be depended on as an infallible *immunizing agent in the sense attributed to* diphtheria serum. Being in the line of natural law, and having preventive and curative properties, it is often a useful remedial measure in a great many cases. It has its sphere of good influence in the hands of the discriminating practitioner. But in a disease as complex and complicated as tuberculosis usually is, we can not, in justice to our patients or ourselves, afford to neglect any and every other means possible to arrest the disease where it exists, and to prevent the occurrence where it is not. Management, climate, nourishment, serum, everything useful should be resorted to, taking care always, in every single case, to treat the patient according to the conditions existing, according to their merits, in other words, individualizing instead of generalizing.

HOW SHALL WE INDUCE IMMUNITY IN TUBERCULOSIS?*

H. B. WEAVER, M.D.
ASHEVILLE, N. C.

When an organism has been infected with pathogenic germs to such a degree as to produce a disease, and spontaneous recovery occurs, a change has taken place, so that the specific germ which produced that disease can find no longer suitable soil for multiplication and growth, and hence its deleterious effects on the tissue-elements cease to exist. This changed condition we call immunity. Some individuals possess this immunity naturally to a marked degree, while others exhibit only a very feeble resistance to bacterial organisms. It is relative also in degree in different races. For instance, tuberculosis is comparatively rare in the Hebrew race, while in the American Indian we find great susceptibility. Immunity is never general, conferring protection against all contagious or infectious disease, but always special, according to the disease, rendering a person perfectly invulnerable to one and not to another.

Some infectious diseases differ, as diphtheria, while others, like tuberculosis, retain their local character for long periods of time.

Statistics show that in from 25 to 50 per cent. [illegible] sies made on the bodies of those who have died diseases, evidences of former tuberculosis are apparent either in the healed or latent form, and in which nature appears to have accomplished the occurrence of immunity against further advance of the disease. That this is a physiologic process there can be no doubt. It has been proven by experiments on animals that artificial immunity can occur by the use of the tubercle bacillus substance in the form of some one of the pure culture products, as that of Koch's tuberculin or of Von Ruck's Watery Extract. If natural immunity is possible in the human subject and artificial immunity can be produced in animal experiments, may we not inquire why natural recovery so often fails to take place?

"Immunity depending on the products of the specific germs, why do the products formed by the tubercle bacilli, in the infected tissues of tuberculous patients, so often fail to induce it, not only in the local and chronic cases, but also in those in which the disease is disseminated?" On a correct answer to this question depends the basic principle of successful therapeutic measures for the real cure of this disease.

In tuberculosis we have no such intoxication as occurs in diphtheria, and formation of tubercles may occur without any acute symptoms. This points to the absence of specific toxins which Von Ruck claims,[1] and with much apparent reason, to be accounted for by the circumscribed localization of the primary lesion, by its slow extension, by its non-vascularity of tubercle, by its rapid degeneration, but above all, by the resistance of the tubercle bacillus to disintegration, and to giving up its contained proteids to the blood, owing to the presence of large quantities of fat in the non-soluble cell-wall composed largely, if not entirely, of cellulose. As a proof that none, or but extremely small quantities, of specific toxins are liberated, he points to the great similarity of tuberculous patients, especially in the early stages, to the artificial introduction of specific toxins, to which they react with general symptoms to a degree that the toxins are used as means for diagnosis. On the other hand, he points to the fact, that beginning with very minute doses, the specific toxins can be introduced in constantly increasing quantities without any general disturbance or toxic symptoms. If he is right, we can readily see why this immunizing substance is not available at a time most needed by the system.

Victor Vaughan, whose views coincide with Von Ruck's, asserts that: 1, marked artificial immunity to an infectious disease has not been obtained except by the introduction into the animal of the germ substance, either inclosed in the cell-wall or in solution; 2, sterilized cultures contain the germ substance in one of these forms; 3, the same immunizing substances exist in the bodies of the bacteria grown on solid media and killed by chloroform; 4, the same immunizing effects, varying, however, in degree, are obtained with bodies of dead bacteria morphologically intact, or in solution, with the living bacteria modified or reduced in virulency." Analyzing these propositions, we infer that acquired (artificial) immunity may be induced in two ways, 1, by an attack of the diseases ending in recovery, and 2, by inoculation with the specific toxin.

The immunity that results from an attack of the disease is caused by the entrance into the organism of living germs more or less virulent, and to whose stimulating qualities the organism is yet able to respond [illegible] causing the obscure change in [illegible] become antagonistic to the [illegible] vaccination in variola is due to the introduction of germs, living, but modified more or less in virulence. That which is secured by the artificial introduction of specific toxins is produced in like manner, but without the presence of virulent germs, the toxins having been separated outside of the body.

---

* Read before the [illegible], Char[illegible] Feb. 21, 1900.

[1] [illegible] 1. p. 94.

With these facts before us, the conclusion is inevitable that the immunizing substance is contained in the bacterial cell, that each kind of pathogenic germ has its own peculiar toxin, which in small doses confers immunity, and it is that part which gives to the germ its distinctive qualities.

The practical methods of inducing immunity reduce themselves to one and the same principle, that is, the introduction of germ toxins into the body.

The immunizing function which has been induced in an individual organism can, however, not be transmitted to another organism. Leaving, therefore, those principles upon which immunity rests, and viewing the question from a practical standpoint, may we not inquire whether we can, in the treatment of tuberculosis, imitate nature in her method of cure, by supplying artificially the toxin of the tubercle bacillus, and introduce it into the human organism in such a manner that it will safely and effectually arouse the latent energy of the tissue-elements, which will in turn produce immunity? The solution of this question rests on the etiologic principles enunciated, and must lead to the conclusions which are eminently scientific and logical.

Are we actually in possession of the required substance, and what is its nature? Is it a toxin or an antitoxin? Can we safely administer it without undue reaction which would be dangerous to the patient, and at a time when immunity would be of no avail, and before the patient is hopelessly doomed?

Is the blood serum from an animal previously treated with specific toxins such a substance?

A horse is rendered immune to diphtheria by the use of specific products of the Klebs-Loeffler bacillus. As a result, an antitoxin is generated in some organ or organs of the horse and circulates in the blood. When the blood clots, the antitoxin is found in the serum. If this serum is injected into a diphtheric patient, in a sufficient quantity and at the right time, the patient will become immune to the diphtheria poison for the time being. But this immunity does not actually belong to the patient. It is stolen property. It still belongs to the horse. The cells of the horse and not the human cells manufacture the toxin. The horse can not transmute any of its antitoxic functions to the sick person.

In tuberculosis we may find a parallel in this illustration. If it be true that immunity consists in the capacity of the organism to protect itself from the deleterious effects of pathogenic micro-organisms, and the tubercle bacillus substance itself is the essence of the bacterial germ which immunizes the system, there can be no reasonable basis for the claim of the production of immunity by antitoxin serum. The adoption of this theory would abrogate the principles of cellular activity. It contradicts a general biologic law that the necessity for a function creates a function, or, stated conversely, the disuse of a function destroys it (Peavy).

Carl Fisch, an exponent of serotherapy, admits that "the amount of toxin present at any one time in a tubercular organism is not great, and it would be absolutely absurd to think that by neutralizing it the disease could be stopped." "Owing to the slow production of the toxin it is impracticable to charge the organism with a great amount of antitoxin, since it would have disappeared long before being called to act." He says further, that the amount of antitoxin in his serum is comparatively small and that there is no present means of increasing its potency, and that beside the toxin immunization, it is the only treatment which rests on a scientific base, and that the imperfections in serotherapy should not be a contraindication for its employment.

From these views we make the deduction that continued protection from tubercular invasion would necessitate the continued introduction of antitoxin, which is impracticable. If an artificially introduced antitoxin is an intimation of nature's method of cure, it would seem reasonable to suppose that, if in a disease as essentially chronic and local as is tuberculosis, immunity is conferred, it would be necessary to supply the system continuously and indefinitely in order to preserve the immunity and prevent a relapse.

Trudeau and Von Ruck in reporting their experiments for the purpose of proving the value of serum preparations for tuberculosis made by themselves and by others, found that in no instance could they discover any germicidal or immunizing properties in the different serum preparations, and seem to accept the plausible theory of Professor Koch, that a serum that would neutralize the toxic effect of a tuberculin product might not prevent the growth of tubercle bacilli in the tissues, nor their destructive action in the organs of the body.

On the other hand, turning to the direct toxin method of cure, we see greater hopes for success. If the immunizing substance is contained in the specific germ only, and the successful immunization with Tuberculin R and Watery Extract of tubercle bacilli has been obtained in the animal experiments, which facts are attested by various colaborers in all parts of the world, why should we hesitate to adopt this method of treatment? Its safety, especially with the Watery Extract, having been observed by myself in patients of Dr. Von Ruck and my own, in all stages of the disease, leaves in my mind no doubt that the immunization of tubercular patients by the direct or toxin method is about to pass beyond the experimental stage, and become one of the fixed and recognized therapeutic modes of procedure in our battle against this formidable enemy of mankind.

The superiority of the Watery Extract over all prior tuberculin preparations consists in the fact that this is a pure solution of the tubercle bacillus substance, repeatedly filtered through porcelain, and therefore containing no fragments of isolated virulent germs, removing the apprehension that through the use of tuberculin preparations the tubercle bacilli might become transplanted to other healthy portions of the body.

Of course, the earlier the disease is discovered and treated the greater will be the benefits from such specific treatment. Its use can not be expected to heal and repair the destructive lesions caused by the softening and liquefaction of degenerated tubercles. All it can do for such is to fortify the remaining healthy tissues against the primary disease, and prevent the eruption of a new crop of tubercles, and the further such cases have progressed in the degeneration and destructive processes the more will it be necessary to bring to our aid the additional resources of diet, hygiene and climate.

New Method of Vaccination Against Anthrax in Cattle.—Arloing states that the successive or simultaneous injection of anthrax virus and serum from an immunized heifer will successfully vaccinate animals. He has succeeded, by using attenuated cultures, in conferring preventive immunity on cattle with a mixture of virus and serum requiring only .5 c.c. of the latter for one animal.

CASE OF FATAL FETAL ICHTHYOSIS.*

ANNIE STURGIS DANIEL, M.D.
Physician in Charge of Out-Practice, N. Y. Infirmary for Women and Children.
LOUISE CORDES, M.D.
Pathologist to the N. Y. Infirmary and Assistant Pathologist to the Babies' Hospital.
NEW YORK CITY.

Maternal History.—Strong, healthy peasant woman, native of Sicily, 30 years old, has never been ill according to the statement of herself and mother. Neither she nor any member of her family has had any eruption of the skin, and no trace of syphilis, alcoholism or tuberculosis in this woman or her family could be elicited. Menstruation began at 14 years and has been regular and normal. There has been no uterine disease. She has had 6 pregnancies: the first 10 years ago; the second 8 years ago; the third 4 years ago; the fourth an abortion at 40 days, the cause of which is unknown; the fifth pregnancy was 2 years ago, and the sixth the present fetus. All of the pregnancies, except the fourth one and the present, were normal in every respect. In January, 1899, the woman was much distressed over the illness and death of her child, which she was nursing. She menstruated in February, 1899, the exact date of which she has forgotten.

History of the Pregnancy.—The woman was much pleased to find herself pregnant. Nothing unusual was noticed until the last two months, when she seemed larger than in former pregnancies and found it difficult to lean forward; for twenty days before the birth of the child she had had much pain in the back. She had worked, as usual, at her occupation of finishing trousers during her entire pregnancy, working from 6 a.m. to 11 p.m. Although closely questioned no history of a maternal impression could be obtained, even after a suggestion that there might have occurred some impression during the pregnancy. Nothing could be ascertained except her grief for the child which had died. The pregnancy terminated October 17, 1899, about two weeks before the woman had anticipated. In the evening of October 15 the woman was seized with pain in the back and a discharge of water. A midwife, who was called, declared that labor had not begun. During the 16th there was some pain and continual discharge of water. After midnight on the 17th, acute pain began and the child was easily delivered by the midwife at 7 a.m. October 17, the head presenting. The mother's recovery was without incident. On the seventh day she was at work again on the trousers.

Paternal and Family History.—Father, 40 years old, is a day laborer, and a strong, apparently healthy man. He is not alcoholic, has had no eruptive disease of any kind, and was never syphilitic. Of the four children born to the couple, two were boys and two were girls. Two are now living. The first died of an unknown disease in Sicily, the last of bronchopneumonia in January, 1899. One of the two living children is markedly rhachitic, as was the child which died in January. The family presents the usual features of east-side, overcrowded, under-fed, ignorant people, and with another family occupies three small rooms, only one of which is light, a total of eleven persons in the apartment.

History of the Child.—It was seen first at 11 a.m., five hours after birth, during which time it had been lying in a dirty bread-pan, wrapped in a single layer of cloth. It had passed both urine and meconium. The child was admitted at once to the New York Infirmary for Women and Children. It was wrapped in cotton, after having been anointed with oil. The child cried continuously, rather a penetrating cry of distress. Sleep was almost impossible. The child was disturbed only to keep it clean, as any jar of the crib or exposure to the air increased the crying. Respiration was irregular. The whole surface of the body was cold, and it seemed almost impossible even with hot-water bags to make it warm. Urine and meconium were passed at intervals. It was utterly unable to suckle, and swallowed milk from a dropper very imperfectly, with great difficulty, and only when the dropper was placed far back in the open mouth. The child died quite suddenly twenty-seven hours after birth. The temperature taken immediately after death was 103 F. The apparently increased distress, at the slightest movement during life, prohibited the making of any ante-mortem examination. The body during life, was at all times rigid and cold, and the extremities remained in the fetal position. The most marked symptoms were the incessant crying and the limited ability to sleep or swallow. So distressing were the symptoms that it was a great relief to the attendants when the child died.

Description of the Child.—The most striking feature is the absence of any resemblance between the child and a human being or any other living thing. The only part of the body that seemed capable of motion was the tongue. The body presents the appearance of having been incased in an integument much too small for the skeleton, and nature in an attempt to make it fit had so stretched the skin that it had been torn in some places completely through, and in others partly through. Where it was torn through, a purple-colored slit appeared; when torn partly through, a yellowish-colored fissure remained. There is no uniformity of arrangement of the fissures. Fewer are found on the back, and those on the extremities are more shallow. Neither is there any uniformity in their length or depth. The color of the fissure, a purplish-red, is in marked contrast to the color of the skin. In a few places bright blood is found, as if the break were of recent origin. The integument gives the same sensation as sole leather, namely, inelastic. The whole body is cold and rigid.

The scalp is divided into fissures and very numerous irregular conical projections, varying in size. A few thin hairs are found on the lateral surface of the scalp. The external ears are replaced by a collection of the conical projections. The external auditory meatus is found with difficulty.

The palpebral fissures are filled with purplish-red masses; deep down in the sockets eye-balls can be distinguished. Neither eyebrows nor eyelashes are numerous, only a few of each being present. The nose is flattened and is identified by the widely-opened nostrils.

The mouth is widely open, showing a non-hypertrophied tongue. The lips are of a purplish-red color and everted. Fissures and conical projections are present on the face. The mouth measures 5 cm. in length and 3 cm. in breadth; circumference of head, 31.5 cm.; glabella to occiput, 18.5 cm.; ear to ear, 15.5 cm.

The neck is short. Anteriorly a fissure extends from the neck to the umbilicus, 2 cm. in width. From this fissure ridges of yellow skin and purple fissures extend toward the axillæ; they are of irregular size and depth. There are eleven distinct fissures on the right side, and thirteen on the left. The circumference of the chest is 28 cm.; of the abdomen at the umbilicus, 28 cm.

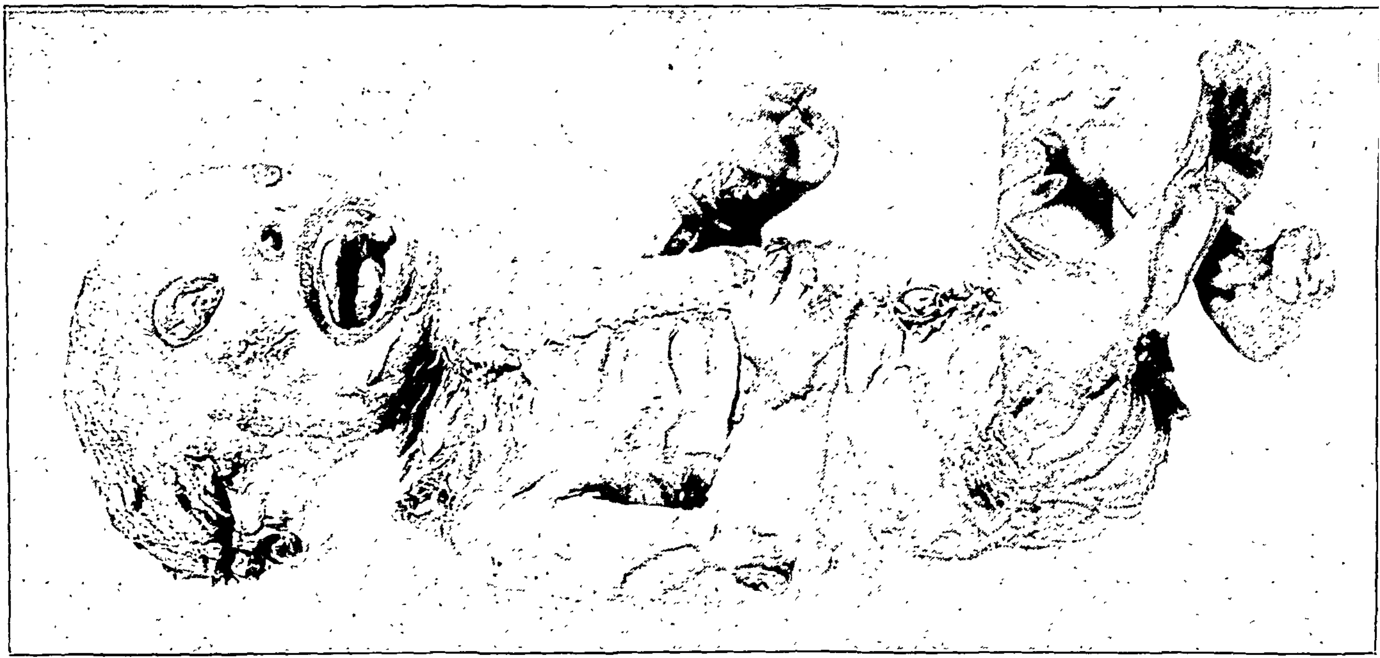
---

*Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The extremities are rigid and in the fetal position. The arms can be raised only at right angles with the body. They can not be extended at the elbow. The hands are thickened and the fingers are rudimentary. The legs are crossed, the right one over the left. The motion at the hip and knee joints is very imperfect. The toes are rudimentary.

The median raphe in the scrotum is faintly marked; testicles are not descended. The penis is ½ cm. in length, and the anus open. The length of the fetus is 42 cm., and its weight is 4 pounds 13 ounces. The placenta was destroyed immediately after birth by the midwife.

Dr. J. W. Ballantyne, of Edinburgh, collected and published in 1895 an exhaustive summary of the cases at that time known. The first case published was by Richter, in 1792. Ballantyne found 42 reported cases. Since then I have found 3 cases, one by Drs. Manning and Southworth, of New York, one by Dr. A. Wassmuth, and one by Dr. Gaetano Finizio, Naples, in *La Pedriata.*



Fatal Fetal Ichthyosis.

Of the cause of fetal ichthyosis practically nothing is known. That it is not a fatal disease *in utero* is demonstrated by the fact that only one case has been stillborn. In my case it was impossible to find any clinical cause for the disease.

An autopsy was performed on October 18, three and a half hours' post-mortem, the body having been kept on ice. A description of the general appearance of this eight-months' fetus has been given by Dr. Daniel.

The upper and lower eyelids are strongly everted, presenting two pouting masses of mucous membrane, which are firmly united throughout their entire extent. Eyeballs are found lying deep in the orbits. Over the right parietal region the scalp is boggy and is raised from the bone by a large amount of blood, which escapes on incision. A hemorrhage covers the superior surface of the cerebellum and medulla, the posterior two-thirds of the left temporosphenoidal lobe, as well as the lower half of the left parietal and occipital regions.

On incision, the skin of the thorax is found to be of leathery consistency and firmly adherent to the muscles beneath; a panniculus adiposus is absent.

The apex of the heart is found in the fifth interspace between the midclavicular and anterior axillary lines. The left ventricle and both auricles contain soft, dark-red clot. The heart muscle is apparently normal. The valves are normal, the foramen ovale showing a slit-like opening.

No pleurisy is present. Both lungs are mottled, bluish-red and pink, showing on section areas of atelectasis together with small areas of well-aerated tissue. Anteriorly there are small areas of emphysema. The middle lobe shows anteriorly a spot of emphysema about three-fourth of an inch in diameter; the remainder of the lobe is well aerated.

The bronchial lymph nodes, thymus and thyroid bodies, spleen, pancreas and adrenals are normal. The liver is congested.

In the stomach the blood-vessels of the mucosa are congested; the organ contains curds and a considerable amount of mucus. The rectum and lower colon are filled with meconium; the mucous membrane and walls of both are normal. The vermiform appendix is normal, containing meconium. The small intestine is normal throughout, the upper portion containing yellow pasty material. The mesenteric lymph nodes are dark-red and normal in size. The kidneys are lobulated and grayish-red; the capsule strips readily and the surface is smooth. On section the cortex is not thickened; the pyramids are pale; the markings are blurred. The bladder is contracted and normal.

Anatomical diagnosis: Fetal ichthyosis, cephalhematoma, meningeal hemorrhage, and atelectasis, with congestion of all the organs.

Material was taken from all the organs and preserved in formalin solution followed by alcohol. Cultures were made on glycerine-agar from the skin, lungs, heart's blood, thymus and thyroid bodies, liver, spleen, and kidneys. A bacillus in pure culture was found in all these organs. This bacillus was grown on the following media: Lactose-litmus-agar, glucose-agar, glycerin-agar, plain-agar, gelatin, potato, glucose, saccharose, lactose and neutral bouillon, litmus-milk and dextrose-free broth.

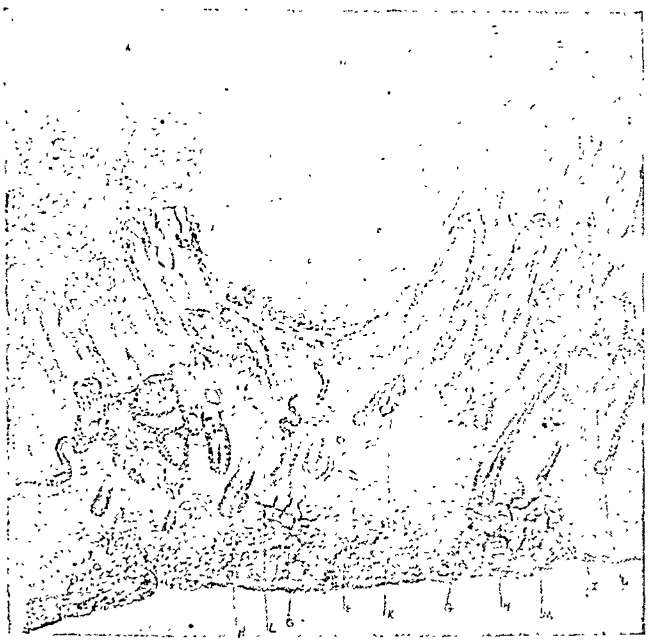
It was also tested by animal experiment, and showed morphologically and biologically all the characteristics of the colon group.

Bacteriological diagnosis: general infection with a member of the colon group.

Microscopic examination: In the skin of an imperfectly developed finger the layers of the epidermis are found less broad than normal. The corium is edematous, but the sweat-glands are normal. Intense congestion of the blood-vessels exists, the capillaries in the papillæ of the corium being widely distended with blood. A few small lobules of fat are found in the subcutaneous tissue.

The layers of the palmar epidermis, with the exception of the stratum granulosum, which consists of three layers of cells, show thickening, which is less marked however than in the skin of the back and chest. The papillæ of the corium are hypertrophied. The sweat-glands are very much increased in number resembling test-tubes in a rack, but are apparently normal in structure.

Sections were made through a portion of the skin of the chest, showing a deep fissure in the epidermis. Considerable hypertrophy of the papillæ of the corium exists. The elastic tissue is diminished in amount, and there is an edematous condition of the corium. The stratum Malpighii is thicker than normal; the stratum granulosum does not appear to be thickened. Both the stratum lucidum and the stratum corneum are much broader than normal, especially the latter, which is enormously increased in thickness . The rupture of the epidermis is in places seen to involve all the layers. The deepest cells of the stratum Malpighii are intact in places, but here and there the fissure extends beyond these, extensive hemorrhage due to rupture of the capillaries in the papillæ having resulted. The skin of the chest contains numerous hairs, whose structure appears to be normal. The sebaceous glands are normal in number, the nuclei of the epithelial cells within their ducts are markedly degenerated in some cases, and a horny layer is found lining the upper portion of the duct. The arrectores pilorum muscles are normal. The blood-vessels of the corium are markedly congested. The panniculus adiposus is poorly developed.



Section of Skin from the Thorax, Showing Fissure.
A. Stratum corneum. B. Stratum lucidum. C. Stratum granulosum. D. Stratum Malpighii. E. Hemorrhage. F. Dilated blood-vessels. G. Sweat-glands. H. Hairs. I. Sebaceous gland. K. Degenerated sebaceous gland. L. Arrectores pilorum. M. Panniculus adiposis. N. Fissure.

As in the sections described above, the papillæ of the corium of the scalp and all the layers of its epidermis are thickened, save the stratum granulosum. The hair follicles are very numerous and most of them are empty. Hairs when found are normal. The sweat-glands are increased in number. The sebaceous glands are numerically proportionate to the hair follicles and are normal in structure.

For purposes of comparison sections were made of skin from different portions of the body of a fetus of six and a half months, as well as of an infant at term.

The umbilical cord is normal. The aorta and the heart muscle of both auricles and ventricles are normal. The blood-vessels of the heart, as well as of all the other organs, are much congested. In the lungs large areas of atelectasis are shown. The thymus and thyroid bodies are normal.

The liver cells show cloudy swelling; the epithelium lining the gall-ducts is normal. The pancreas and adrenals are normal. Kidneys: general connective tissue normal; the epithelium of the secreting tubes shows granular degeneration, groups of tubules containing exudate; the epithelial lining of the loops is normal and the latter contain no exudate; the same may be said of the collecting tubes. All the blood-vessels are congested. The epithelium lining Bowman's capsules is slightly swollen in places; the Malpighian tufts do not all fill their capsules, the space between tuft and capsule occasionally containing exudate.

The intestine is normal but the peritoneum is edematous.

The mesenteric lymph nodes are normal, save for marked congestion of the blood-vessels.

Sections from the cerebral motor cortex, ascending frontal and occipital convolutions, as well as from the paracentral lobule, show edema of the pia and hemorrhage into its tissues. The brain substance appears to be normal.

The blood-vessels and nerves studied in numerous sections from the different organs are quite normal.

Sections stained for bacteria show rods scattered and in groups in the blood-vessels as well as between the tissue elements. In the skin, bacilli are found between the cells of the epidermis, having penetrated as far as the cells of the stratum corneum. The organism found was probably the result of a terminal infection, and not an etiological factor in the production of the disease.

Microscopic diagnosis: Ichthyosis, atelectasis, acute exudative nephritis and congestion of all the organs.

SUMMARY.

1. All the layers of the epidermis, save the stratum granulosum, are thickened, notably the stratum lucidum and the stratum corneum; the latter is enormously hypertrophied.
2. The corium is edematous and contains less elastic tissue than normal. The papillæ of the corium are hypertrophied and their blood-vessels are widely distended with blood.
3. The sweat glands are in some places markedly increased in number, but are normal in structure.
4. The sebaceous glands are normal in number, but their ducts in some cases, and occasionally their secreting portions, show degenerative changes. The arrectores pilorum muscles are well developed.
5. The panniculus adiposus is everywhere poorly developed, being almost absent in places.
6. The kidneys show the lesion of acute exudative nephritis. In the liver there is granular degeneration of the hepatic cells and the meninges of the brain show extensive hemorrhage. The other organs present no pathological changes save intense congestion.

Congenital ichthyosis has been studied by numerous observers. Ballantyne[1] made a very thorough study of the disease. He regards the descriptions of the microscopical appearances of the integument given by Kyber[2] and Carbone[3] as the best. The latter considered that the thickening of the epidermis was due entirely to hypertrophy of the stratum corneum. The rete Malpighii, with the exception of the interpapillary prolongations, he described as not only not thickened but in places actually diminished in breadth. He denies the existence of a stratum lucidum. The external root sheath of the hairs he finds greatly thickened and the hairs abnormally thin. According to Carbone's description, the sebaceous glands are usually atrophic. Occasionally the horny layer extends into the sebaceous ducts, the entire gland being at times converted into a cavity surrounded by horny walls. He finds no hypertrophy of the sudoriparous glands, noting only that that they are well developed. Kyber differed from Carbone with regard to the stratum Malpighii, describing it as increased in thickness and possessed of greater proliferating activity. He finds the sudoriparous glands hypertrophied. Ballantyne states that the corium does not show in fetal ichthyosis any marked departure from the normal.

[2] Eine Unte rsale
Keratom der mens
[3] Un Caso di It le
1891. xv, p. 349.

The discrepancies seen in the pathological findings of Carbone and Kyber, Ballantyne explains by assuming that the case of Kyber was a more marked one than that of Carbone.

A. Wassmuth[4] in 1899 described the microscopic appearances in the skin of a case of congenital ichthyosis born at term. He notes thickening of the layers of the epidermis; in places he finds nucleated cells containing granules of keratohyalin, but he accentuates the fact that a proper stratum granulosum was not demonstrated anywhere save in sections of the scalp. The stratum corneum he found to be thickest in the scalp, palms and soles, and thinnest in the skin of the chest and abdomen.

Wassmuth found that different lamellæ of the stratum corneum respond variously to stains; he employed Gram's stain, recommended by Paul Ernst, for the detection of keratin, staining sections of the skin of fetuses of various ages as a control. He reached the conclusion that a differentiation of a stratum granulosum, stratum lucidum and stratum corneum in the integument in congenital ichthyosis is not possible, the early stages of keratinization occurring throughout the entire epidermis. Wassmuth emphasizes the fact that a fully developed stratum corneum does not exist, explaining in this way the abnormal breadth of the epidermis.

The stratum corneum is relatively thin in embryos as a result of maceration, which causes desquamation of the superficial layers. In cases of fetal ichthyosis exfoliation occurs only in moderate degree or not at all, and Wassmuth believes imperfect keratinization to be the cause.

Thickening of the stratum Malpighii, he thinks, accounts in part for the hyperplasia of the horny layer; furthermore the enlarged and numerically increased papillæ with their proportionately more complex capillary networks aid the increased development of the epidermis. He describes the papillæ of the corium as very high and numerous, "enormously increased in all parts of the body" and containing rich networks of distended capillaries. The sweat glands are described as everywhere increased in number and normal in structure. The sebaceous glands are increased in number everywhere save in the scalp; they are frequently somewhat enlarged and their ducts are at times distorted, being dilated and lined with a horny layer. The elastic tissue of the corium is diminished in amount and the panniculus adiposus he describes as well developed in skin removal from the back of the neck.

Recently G. Finizio[5] reported a case of fatal fetal ichthyosis.

A microscopical examination of the the skin of this fetus showed the stratum Malpighii to be of variable depth; in some places thicker, in others, especially on the plantar surfaces, thinner than normal. Mitotic figures are not more numerous than in the skin of a normal fetus of the same age.

Finizio questions the presence of a true stratum granulosum, but finds numerous cells with protoplasm containing deeply staining basophilic granules.

A well-defined stratum lucidum was not found; the layers of the stratum corneum are wavy in outline and have a reticular appearance. The connective tissue of the corium is infiltrated with lymphoid cells, the elastic tissue being normal.

The papillæ are numerous, large and richly vascular.

The sebaceous glands are well developed, some acini showing dilatation and degenerative changes. The sudoriparous glands and the arrectores pilorum muscles are well developed, the former especially on the plantar and palmar surfaces.

It will be seen that the microscopic appearances of the case described in this paper resemble in many respects those noted by Kyber and Wassmuth.

As a result of some influence not understood, the epithelial elements of the skin in this disease are apparently stimulated to active growth, the rete Malpighii sharing the general tendency to cell proliferation. Consequent upon this proliferation, the glands which are offshoots from the stratum Malpighii are increased in number. To meet the increased nutritional needs of the rapidly-growing epidermis the papillæ of the corium enlarge and multiply.

Discussion will appear next week.

GASTROINTESTINAL HEMORRHAGE IN THE NEW-BORN.*

EDWARD H. SMALL, A.M., M.D.
PITTSBURG, PA.

On Sept. 18, 1899, a fine, plump baby girl, eight pounds in weight, was born. The mother was a primipara, and her period of gestation 290 days. The family history on both sides was good.

Labor pains came on strong at 12 a. m., and as they continued, but with little advance of the child, forceps were applied at 5 p. m., delivery being quite difficult. The cord was cut in about five minutes after birth. The child was somewhat asphyxiated, but in a few minutes was breathing nicely. She was put to the breast in about one-half hour, when she sucked finely. All the next day she nursed well, as all healthy babies should do. Her bowels were moved and she passed water freely.

On September 20, at midnight, when the baby was 31 hours old, she vomited and passed by the rectum some material which looked much like meconium. I saw the child in twenty minutes, when she seemed all right, but the nurse said that she had been cold and somewhat collapsed just after the hemorrhage. The material she had passed both by the mouth and rectum, looked like meconium mixed with blood. At 2:15 a. m. she passed some more material by the rectum, but none by the mouth. This was almost pure blood and quite profuse. It looked like the hemorrhage of typhoid fever. At 4 a. m. she had another hemorrhage per rectum. This was of pure blood, very profuse, saturating the napkin. She was in a state of great collapse, extremities cold, pulse scarcely perceptible, and I gave her 1/150 gr. of the sulphate of morphia and 1/5000 gr. of atropia hypodermically, applying warmth to the extremities. Albumin water and brandy were given by the mouth, and the child was enveloped in absorbent cotton, especially about the pelvis.

At 8 a. m. still another abdominal hemorrhage of pure blood occurred, and saturated the cotton; this left the baby practically bloodless, and the pulse imperceptible. She seemed to have lost all her fat, was all shriveled up, and looked like a child after an attack of cholera infantum. At 2 p. m. she passed a few dark clots. Her condition was now desperate, and she was very restless and irritable, with temperature 104 F. An ice-cap was put to the abdomen, hot-water bottles to the extremities, and albumin water and brandy given as before. One minim of aseptic ergot was given hypodermically. At 7:30 p. m. she was quieter, her pulse perceptible, temperature 99 F., and at 11 p. m. she was resting fairly well.

On September 21 she was crying, had slept some during the night, and had passed a normal stool. At 8 a. m. her temperature was 99F., and pulse stronger. At noon it was still stronger, and she took nourishment better. At 5 p. m. I ordered milk from the Walker-Gordon laboratory, as she would not nurse.

September 22, at 8 a. m., reports showed she did not rest well during the night, and refused all nourishment. At 4 p. m. she nursed for the first time since she had the hemorrhage.

On September 23 reports showed that she slept well during the night and was nursing well.

From this time on the baby continued to improve, though very weak and thin for several weeks. In about one month she was doing as well as though nothing had happened, and is now healthy. The umbilical cord did not separate until October 6, eighteen days after birth.

A great many causes have been given for this affection: infection; sepsis; hereditary syphilis; tuberculosis; hemophilia; purpura hemorrhagica; fatty degeneration of the fetus; plethora; general feeble state; atelectasis; cyanosis; asphyxia; tardy establishment of the respiratory and circulatory functions; congenital malformations of the heart; enlargement of liver and spleen; acute infectious disease, as smallpox, measles, etc.; change in the blood or blood-vessels; too speedy ligature of the cord; slow and difficult labor; external violence; irritant matter in the gastrointestinal canal, as worms or retained meconium; ulcers on the gastrointestinal surface, and hyperemia of the mucous membrane of the alimentary tract. Of all these causes but few were present in my case: asphyxia, tardy establishment of the respiratory and circulatory functions, and slow and difficult labor.

*Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

It is probable that one or more of the above etiologic factors are present in most of the cases and may possibly act as exciting causes, but these are so often present in thousands of births, in which no hemorrhage is seen, that it is difficult to assign one cause for many cases.

The fact that so many more of these cases occur in institutions than in private practice would point to an infectious nature. Drs. Kilham and Marcelis[1] report ten cases of hemorrhagic disease in the new-born as occurring in 54 births between Feb. 19 and May 11, 1897, in a New York Maternity, or 18 per cent., of which 5 had hemorrhage from the bowels and 2 from the mouth. The ward was entirely free from sepsis, there was no apparent cause for the hemorrhage, and the cases followed one another in quick succession, often overlapping, and ceased when proper measures were taken for isolation. Dr. Townsend[2] reports, in 6700 births in the Boston Lying-in-Hospital, 45 cases, or .67 per cent.; while in the out-patient department there were but 4 cases, or .1 per cent. This comparative prevalence in the hospital has no connection with septicemia, as the disease is practically eradicated from that institution, but occurs independently of it, just as thrush may get a foothold and flourish in a hospital, although it is not common in private practice.

Drs. Kilham and Marcelis made bacteriologic examinations in two of their cases and found an organism suggesting the diplococcus of pneumonia and probably belonging to the pneumococcus group. Gaertner found, in two cases, a short bacillus much like the bacterium coli commune. This bacillus, injected into the peritoneal cavity of young animals, chiefly dogs a few days old, produced a disease accompanied by hemorrhages resembling that seen in the newly born. (Holt.) Other observers have found various organisms: the streptococcus alone or associated with an organism having all the characters of the diplococcus of pneumonia; bacillus pyocyaneus alone or associated with the staphylococcus; bacillus lactis aerogenes; an organism with the characters of Friedlaender's bacillus. At present the results of bacteriologic examinations are very much confused, but they all seem to point to a specific cause.

The very definite course of this disease, soon ending in death or complete recovery; its self-limited nature; its greater prevalence in institutions; the elevated temperature, as in my case; the fact that it is in most cases a general and not a local disease, not limited to one spot, and the bacteriologic findings, all point to its infectious nature and suggest its relationship to the acute infectious diseases.

Hereditary syphilis is present in a small proportion of cases. Sepsis seems to be associated with a large number. Hemophilia is a different disease from this. It is an inherited one whose hemorrhagic tendency continues as long as the patient lives. Bleeding in hemophilia rarely occurs before the end of the first year of life. In hemorrhagic disease the sexes are about equally represented; while in hemophilia the proportion of females is 13 to 1. Circumcision has been done within a few days after recovery from the bleeding of gastrointestinal disease without any unusual hemorrhage.

Holt says that there is a class of cases in which the hemorrhages are not associated with any known process. These are characterized by the fact that they are spontaneous in origin, having no connection with delivery. They are most often from the umbilicus, the mucous membrane of the stomach and intestines, or beneath the skin, but they may be from almost any mucous surface or into any organ of the body. These hemorrhages probably arise from changes in the blood or in the blood-vessels, or in both, whereby the vessels are no longer able to hold their contents. The predisposing causes of bleeding in early life must be emphasized, viz: the fragile condition of the blood-vessels and the great changes taking place soon after birth in the circulation and in the blood itself.

Jacobi[3] says that the round perforating ulcer in children is more frequently met with in the newly-born and quite young than in advanced childhood. The causes of gastric and duodenal ulcers are very numerous. Some enumerate among these arterial anemia, others venous hyperemia or stasis in the hepatic vessels; or circumscribed hemorrhages into the tissue. Others assign thrombosis as the cause; others emboli, or lessened alkalinity of the blood, or hemoglobinuria. In this way hemorrhages and ulcers frequently go hand in hand, and often are the cause of each other. In the newly born, hemorrhages from the digestive tract are known by the name of melena. In the majority of cases melena occurs from localized and circumscribed ulcers, or from rupture of blood-vessels between the first and third day of life, rarely after the first week. It is caused by the sudden changes in the circulation occurring at and after birth. At that time, and from the same causes, is hyperemia of the mucous membrane found extensively, even in healthy babies. Hyperemia results in hemorrhage very much more frequently in the newly-born and in infants, because of the thinness and permeability of the walls of the blood-vessels.

This is a very serious disease. Probably one-half of the patients die. The mortality, acording to a number of writers, varies from 35 to 79 per cent. Townsend collected 709 cases showing a mortality of the latter figure. The prognosis in an individual case depends on the physical condition of the child, on its ability to take nourishment, and on the amount of blood lost. That the most desperate cases may recover is shown by mine, seen by several medical friends, none of whom would venture a favorable prognosis.

Townsend says: As regards treatment, if we have in mind that the disease is self-limited, we will not give up the case as hopeless, but will do everything to tide it over the critical period. Perfect quiet, most careful and persistent feeding from spoon or dropper, with milk drawn from the mother or wet-nurse, or careful artificial diet, may be all that is necessary to prevent a fatal issue. Warmth in the stage of collapse and alcoholic stimulants even in the stage of bleeding seem to be beneficial.

Holt says that the administration of drugs internally for the control of hemorrhage is entirely without influence on the disease.

Others recommend cold drinks, ice, ergotin, gallic acid, perchlorid of iron. If collapse is present, inhalations of oxygen, counterirritation, [illegible] normal salt solution are of use. [illegible] re[illegible] injections of astringent solutions, with the idea of reaching the site of the bleeding. This, however, is scarcely practicable.

[3] Intestinal Diseases of Infa

The most recent mode of treatment is the use of a solution of gelatin, both by the mouth and by the rectum, with a favorable result in one case. My use of morphia hypodermically seemed to do more good than anything else. I looked upon this case as somewhat akin to the abdominal hemorrhage of typhoid fever, in which I use morphia similarly.

Discussion will appear next week.

CHRONIC INFLAMMATION OF THE TEAR PASSAGES.*

WILLIS O. NANCE, M.D.

Assistant Surgeon Illinois Charitable Eye and Ear Infirmary; Professor of Ophthalmology, Chicago Clinical School.

CHICAGO.

Lachrymal disease constitutes from 2 to 3 per cent. of all eye cases. Of 95,596 patients treated in the eye department of the Illinois Charitable Eye and Ear Infirmary between the years 1859 and 1898, 2147, or about 2.25 per cent., suffered from disturbance of the tear-conducting apparatus. Females seem more liable to be affected than do males, in the proportion of at least 2 to 1. This statement seems somewhat strange from the fact that the latter suffer much more from atmospheric exposure, undoubtedly an indirect etiological factor of considerable importance. Fuchs explains this predisposition on the part of women to the "zealous use which the female makes of the lachrymal apparatus." We find the disease occurring in all ages. C. W. Hawley[1] has recently reported five cases of mucocele in the new-born, and clinical experience demonstrates that infants are frequently sufferers from lachrymal disease.

Any obstacle to the performance of the physiological function of the ocular drainage apparatus may bring about the condition commonly known as "watery eye." The normal overflow of tears may be impeded by malposition of the lids, stenosis or occlusion of the punctum, canaliculus, or nasal duct.

In order to thoroughly appreciate the pathologic conditions present, some knowledge of the anatomy and physiology of the parts is necessary. The conducting apparatus begins with two minute orifices, the puncta lachrymalia, situated on the free borders of the lids, and lying in contact with the eyeball, about two lines from the inner canthus. These openings lead into minute canals, the canaliculi, which pass inward and empty into a reservoir, ovoid in shape, the lachrymal sac. The dilated lower extremity of this sac forms the upper part of the nasal duct, which extends downward to its exit in the inferior meatus of the nose, the membranous walls forming valve-like folds at close intervals. Anatomically, there exists an intimate relationship between the lining membrane of the nasal duct and that of the turbinate bodies of the nose, this condition being of importance in view of the statement to be made later on concerning the etiology of dacryocystitis.

The normal function of lachrymal conduction is vested in a delicate mechanism in which the act of winking, capillary attraction of the canaliculi, muscular contraction of the sac, and valvular suction of the nasal duct undoubtedly play important parts.

The lachrymal sac is subject to both acute and chronic inflammatory attacks; the one occurring with all the usual symptoms of suppurative disorganization, the other, a sequel of an acute attack of severe inflammation, or often a quiescent inflammatory condition without previous subjective manifestations. The patient complains of a flowing of tears over the cheek. The eye is said to be "watery," and at the least exposure to wind or dust, fairly "swims" in tears. The vision is more or less interfered with, a frequent wiping of the eye is necessary to bring about a clear image. There may be present a blepharitis or an eczematous excoriation on the cheek in the region of the inner canthus, the result of irritation from the continuous overflow. There is generally present a distension of the tissue over the lachrymal sac, which may or may not have received the notice of the patient. The more observant will have discovered that pressure in this locality has caused a flow of viscid matter to enter the eye, or in exceptional cases to flow into the nostril. In a minority of cases, where there has not been sufficient retention of fluid in the lachrymal sac to distend the walls, mucocele may not be present.

The question often arises in a case presenting manifestations of epiphora, whether the excess of tears does not arise from some other cause than that of interference with the normal outflow. We all know that exposure, at times, to the elements, offending particles of dust, obnoxious gases, refractive asthenopia, photophobia from inflammatory conditions of the eye, atony of the muscles of the lower lid without noticeable malposition of the punctum, senility, violent outbursts of emotion, sneezing and vomiting, may cause an overflow of lachrymal secretion. In a suspected case, then, we have two methods to aid us in a clear determination of the case: 1. In a case of lachrymal blennorrhea, on making direct pressure over the lachrymal sac, the swelling will be felt to give way under the manipulation, and in most cases the viscous discharge already spoken of will be seen to exude from one or both the puncta on the margins of the lids. 2. The forcing of fluid through the passages into the nose will be found to be exceedingly difficult in chronic inflammation of the tear sac, the swollen and thickened walls or strictured lumen of the duct preventing free patency. Besides, a careful examination of the lids and eyeball for inflammatory manifestations and a thorough research into the refractive condition of the eye will, in many cases, tend to clear up any doubt concerning this symptom.

Inflammation of the lachrymal sac is, in most cases, undoubtedly an extension of a similar process from the nasal mucous membrane. The similarity of anatomical construction between the lining membrane of the nose and the nasolachrymal duct renders this extension easy of consummation. One would naturally expect, also, an extension of inflammatory process from the other end of the lachrymal tube, from the conjunctival surface as well, but it seems that this source of infection does not play an important part. In proof of this statement, it may be said that we very rarely encounter dacryocystitis as a complication of gonorrheal conjunctivitis or other severe ocular inflammation. On the other hand, it must not be forgotten that the conjunctiva and cornea are extremely susceptible to infection from perverse lachrymal discharge, especially if there be present an abrasion of the tissues. This matter is of extreme import to the surgeon, who should undertake no operative procedure on an eye thus exposed without at first removing or modifying the conditions present, and to the patient, whose chief danger from dacryocystitis lies in the extreme susceptibility of the wounded ocular tissues to infection.

---

* Read before the Illinois State Medical Society, held at Springfield May 15–17, 1900.

[1] The Journal, 1900, Vol. xxxiv, p. 401.

Patients suffering from lachrymal disease have been, as a rule, subject to frequent attacks of coryza, and on examination will be found to present abnormal nasal processes. The extension of the inflammation has, by swelling and infiltration, narrowed the normal lumen of the duct, and in this way has formed an obstacle to the normal outflow of the secretion. The tears, conveying the micro-organisms which exist more or less constantly in the conjunctival folds, and which under physiological conditions are carried away to the nasal fossæ, are retained in the lachrymal sac, where exists an excellent chamber for the culture of bacterial organisms. The impediment to the outflow of retained secretion varies, in different cases, from a simple occlusion from swollen membrane and inspissated mucus to a true stricture of cicatricial formation. The latter condition, I contend, exists in not more than one-fourth of all cases, and where it is present is, in many instances, the result of faulty technique on the part of the surgeon in the passing of probes.

Chronic inflammation of the lachrymal sac sometimes occurs as a sequel of smallpox, measles and scarlet fever, exanthemata which present symptoms of nasal inflammation and irritation. Syphilis, by its necrotic inroads of the bony canal, may bring about an attack of dacryocystitis by mechanical obstruction of the passages.

The treatment of chronic inflammation of the lachrymal sac and nasal duct should be directed, 1, toward the removal of pathological processes and malformations of the nasal chamber, instrumental in the causation of the trouble in the vast majority of cases; 2, toward the restoration of the patency of the passages, with as little damage as is possible to the normal anatomical relations; 3, toward the alleviation of all factors conducive to the production of ocular irritation, reflex or otherwise, and 4, toward the proper correction of any existent dyscrasia.

The nasal fossæ should in all cases receive careful attention. Any abnormalities of the turbinate bodies should be remedied, especial consideration being paid to the immediate locality of the nasal duct outlet. The character of the nasal discharge should be modified by the frequent and thorough application of some alkaline spray, of which Dobell's solution is probably as efficacious as any.

The restoration of the normal caliber of the passages is a matter of the greatest importance, and the method in which this may be accomplished and drainage apparatus once more be made to perform its physiological function, is a problem on which ophthalmologists hold widely different opinions. Some surgeons slit one of the canaliculi and pass probes in every case, as soon as the diagnosis of tear-duct inflammation is made. Some incise the lower canaliculus exclusively, others the upper, and some, again, both. Some advise rapid dilatation by probes; others gradual dilatation. Some use probes of the minimum caliber, and increase only to a very moderate size; others use nothing smaller than a No. 8 Bowman, and frequently pass a No. 16 Theobald. Some, after slitting the canaliculus, insert a style; others, a canula. The passage of a probe is supplemented by some by a current of electricity; others have suggested the use of a medicated gelatine bougie as a substitute for the metal probe.

This wide variance of opinion regarding the management of these cases only tends to show with what degree of nebulosity we recognize the pathological conditions as they exist, and how empirical, to say the least, is our accepted mode of treatment.

In the first place, let us carefully examine and study each case as it presents itself, and determine as to the pathological conditions present. The dilatation of the punctum and the injection of a simple antiseptic, accompanied by scrupulous attention to the nasal chamber as before suggested, will in a certain number of cases suffice to relieve the constricted lumen of the passages and restore physiological patency. In those cases in which pressure on the sac causes a purulent discharge to exude, or the method just mentioned persistently carried out for several weeks, does not bring about an amelioration of the symptoms, one of the canaliculi should be slit up and a probe passed. The probes devised by Bowman are in general use. The question as to which canaliculus, the upper or lower, should be operated on does not seem to me to be a matter of much importance. Two points, however, should be borne in mind in performing this little operation: 1, make the incision entirely on the conjunctival surface of the lid by inclining the cutting edge of the knife slightly toward the eyeball; 2, slit up as little of the canal as is possible to allow of the passage of the probe. One-third of the length of the canaliculus is generally sufficient. By observing these simple rules the normal capillary or suction function of the canal, so necessary to retain, will be maintained.

One of the smallest probes should be immediately passed and repassed daily for two or three days, in order that the edges of the wound may not heal; after this short period, the intervals may be lengthened from two to three times a week to once a week, or even longer. The introduction of probes larger than a No. 8 Bowman in cases where there exists no true stricture of the duct seems to me to be wholly unnecessary in the average case, and to be extremely liable to injure the membranous walls of the passages, produce further thickening and cicatricial formation, and destroy the delicate valve-like folds of the nasal duct, even when exceptional care has been displayed in their use. In this connection it may be well to emphasize the importance of gentleness and precision in the passing of probes. One can not exercise too much care in their manipulation lest he aggravate the conditions already existing. A little patience and perseverence will oftentimes prevent harmful sequelæ. Another point to bear in mind is the importance of passing the probe the entire length of the nasal duct, for, as is well known, a common location of occlusion or stricture is at or near the duct exit in the inferior meatus. It is well, when in doubt, to examine the nasal chamber by reflected light, and with a fine applicator feel for the probe in position. The introduction of a No. 6 Bowman probe—having a caliber of 1.5 millimeters—will often give some idea as to the nature of the constriction present. If such a probe is evenly gripped and the impression conveyed that the walls are smooth, even though considerable steady pressure be required for introduction, we may conclude that there exists no true cicatricial stricture. Where the diagnosis of cicatricial stricture is made, the larger probes, or those of Theobald, may be employed. As before stated, however, true stricture of the nasal duct occurs in but comparatively few cases, consequently the passage of the Bowman series will, in most cases, suffice.

Probes sh [illegible] ition for [illegible] nutes, withdrawn [illegible] ed wit [illegible] tic or astringent solution by means of Anel's syringe. The saturated solution of boric acid is commonly used for this purpose. During the past year I have employed a 5 per cent. solution of argonin as an injection, and am led to believe it to be more efficacious than the boric or other solutions formerly used.

The home treatment of these cases forms a valuable adjunct to their successful management. The patient, or preferably an intimate associate, should be instructed in the method suggested by Gould, of alternate pressure and relaxation of the lachrymal sac, the patient reclining, the eye immersed in some antiseptic solution. This manipulation should be performed several times a day, with the end in view of emptying the sac of its effete contents and forcing the solution into the passages.

Refractive errors should be carefully corrected and constitutional disturbances remedied. Exercise in the open air and cold baths are indicated in the majority of cases. In cases unable to undergo a protracted course of treatment, the lachrymal canula or style may be employed. My experience in this connection, though somewhat limited, has been disappointing, and I seldom make use of them.

The instruction of the patient, or some member of his family, in the passing of probes, has been suggested by some surgeons for those unable to continue office treatment. This procedure I cannot approve of, for the reason that the maneuver, as already stated, is an exceedingly delicate one and should not be entrusted to the inexperienced. If the sufferer be unable to carry on the combined office and home treatment for a reasonable length of time—say three or four months—the canula may be made use of until satisfactory arrangements may be made to attend regularly.

The ancient practice of sac extirpation in obstinate cases has recently been revived. It seems to me to be justifiable as a last resort in intractable cases, although one must not overlook the fact that complete obliteration precludes the possibility of natural drainage, which sometimes comes about in seemingly incurable cases when the inflammatory trouble has subsided. Preliminary to operations on the globe in lachrymal cases, obliteration is, of course, justifiable and obligatory.

100 State Street.

A FEW POINTS ON APPENDICITIS.

J. HENRY BARBAT, M.D.
SAN FRANCISCO.

Probably no other disease has brought forth such an array of literature as has been published within the past ten years on appendicitis. All classes of practitioners took a hand, and the result is an indescribable melange, which we are slowly untangling, but we are beginning to get order out of chaos. The medical man is slowly recognizing that appendicitis is a surgical disease, and no longer delays calling in the surgeon until the patient is beyond hope. Surgeons who a few years ago advocated waiting so many days in most cases are now advising operation as soon as the diagnosis is made.

The question of diagnosis is the key to the peculiar statistics which we sometimes see published by men who claim to cure all their cases without operation. All belly-aches are appendicitis; and when a patient dies from a neglected case of the true disease it is laid to the door of inflammation of the bowels, obstruction of the bowels, or idiopathic peritonitis. While we are all liable to err in our diagnoses, it is better to err on the safe side, and remove an appendix which is not diseased than to leave one in which is going to cause the death of its owner.

As our experience increases we are able to eliminate practically all the conditions which simulate appendicitis, but that is as far as we can go. It is absolutely impossible to differentiate the varieties of this disease by the symptoms present; we can occasionally, under favorable conditions, palpate the appendix with sufficient thoroughness to say positively whether it is distended or contains a calculus; but as a rule either the tenderness is too great or the abdominal wall too thick to determine with any degree of accuracy the condition of the appendix.

What then have we to rely on to make our diagnosis, and how shall we do it? The first and one of the most important diagnostic features, is the suddenness of the attack; the pain coming on with little warning and increasing rapidly, in a person otherwise apparently healthy. The locality of the pain is not diagnostic; it may be, and usually is, near the umbilicus, or it may be in the epigastrium. The next point is the nausea or vomiting; we find either one or the other present in about 90 per cent. of all cases. Constipation is the rule. Localized tenderness is found within the first few hours in practically all cases, and in 90 per cent. it is at or near McBurney's point. The diagnostic tripod consists therefore of sudden pain in the abdomen, nausea or vomiting, and localized tenderness.

The majority of mistakes are made by failing to obtain an exact history of the first few hours of the attack. If the physician is not called in until twenty-four or more hours have elapsed after the onset of the disease, and relies for a diagnosis on the symptoms which are found at that time, he will often be led astray, because it often happens that the pain and tenderness have either subsided or disappeared, and the condition does not look serious. This is very deceptive, as we often find in these cases that either perforation or gangrene has taken place, and nothing but an immediate operation will save life.

We meet with a number of cases in people otherwise healthy, in which deep pressure over the appendix causes pain, indicating either a slight catarrhal condition or the existence of adhesions. The patients will have occasional attacks of increased pain and tenderness, especially if they become constipated. Operation is indicated if the pain and tenderness are sufficient to prevent the individual from working, or prevent him from enjoying life comfortably. We can differentiate these cases from most of the other varieties by the fact that we do not find the exacerbations coming on suddenly, but rather a progressive increase of pain beginning indefinitely.

One very important consideration is the fact that the temperature and pulse at the beginning of an attack must not be taken into consideration in determining the question of operation. I mention this because several have stated that they depended to a certain extent on the temperature and pulse in guiding them. The fallacy of this is shown by the following cases:

Case 1.—W. B.; history of probable attack six months previously. He was awakened one morning at 3 a. m. with severe pain in abdomen, and vomited. I saw the patient an hour later and found extreme tenderness over McBurney's point, temperature and pulse normal. Operation ten hours later; appendix four inches long, with distal three inches filled with pus and becoming gangrenous; a complete obstruction prevented the pus from getting into the cecum.

Case 2.—H. B., had attack eight and a half years previously with formation of subphrenic abscess. Sudden pain at 4 p. m. with slight nausea, no increase in pulse or temperature. Pain and tenderness increasing; patient was operated on at 8 p. m. Appendix distended and contained five appendoliths; the tip was imbedded for three-fourth of an inch in tough cicatricial tissue, the result of the previous attack.

Case 3.—Patient came to office forty-eight hours after the first pain; had had nausea and vomiting and felt very sick. When I saw him the pulse and temperature were normal and the tenderness was not very great; but I was able to find some thickening at the site of the appendix, and advised operation. Next day the patient stated that he was entirely free from pain and tenderness and felt all right, but I still advised operation on account of the initial symptoms and the fact that I could feel something hard at the site of the appendix. Operated seventy-two hours after the beginning of the attack, and found the appendix extremely large and containing a very large appendolith. The mucosa and submucosa were sloughed at the point of the junction of the appendix and cecum, leaving nothing but the peritoneum to hold the appendix in place.

These cases show clearly that we can not in any case determine the pathology by the physical signs, or the subjective symptoms; for we find the most desperate pathologic conditions with the mildest symptoms, and vice versa; the classical symptoms well marked with but slight pathology. This can be easily understood, when we consider the cause of the various manifestations. Pain is produced by pressure on the sensory nerves, and therefore a congestion will produce more pain than a complete gangrene, and the bursting of an appendix will relieve the pain that was caused by its distension. The moment the pressure ceases, or the nerves are destroyed the pain and tenderness disappear.

The nausea is reflex and may be marked in the mildest and almost absent in the worst case. The rise of temperature and increased pulse-rate depend on the absorption of ptomains by the system, and it is possible to have a complete gangrene of the appendix without having sufficient poison absorbed to cause a rise of temperature; again we may have a slight erosion of the mucosa allowing a free absorption of the products of decomposition of the bowel, running the temperature up as high as 104 F. The pulse varies with the nervous system of the individual and therefore can not be taken as a guide in determining the question of operation.

We are left, therefore, without any reliable means of determining the condition of the appendix in any given case without opening the abdomen, and we consider that the mortality after operations which have been performed within the first forty-eight hours is practically nil. We are certainly justified in advising immediate operation in all cases in which the classical signs were manifested within the first few hours.

Much depends on the method of operating. Except when pus is undoubtedly present, our primary incision should be small, just sufficient to admit one or two fingers, and the conditions ascertained by careful exploration. If recent adhesions are found, the incision had better be enlarged sufficiently to be able to see every step of the operation, as these cases are the ones in which the operation may prove dangerous in inexperienced hands. From a comparatively trivial operation, which is necessary in perfectly clean cases, we come to an operation which taxes the skill of the most expert abdominal surgeon, and which may require the resection of a portion of the bowel.

My conclusions are as follows:

1. That over 90 per cent. of cases of true appendicitis which are not operated on have recurrences.
2. That we should operate on all cases of chronic recurrent appendicitis, if possible between attacks.
3. That in practically all cases which die after operation we find at least forty-eight hours between the onset of the attack and the time of operation, therefore it is reasonable to assume that if these cases had been operated upon inside of the forty-eight hours the patients would have been cured.
4. That as soon as a diagnosis of acute appendicitis is made, operate immediately.
5. Pulse and temperature are not to be taken into consideration in making a diagnosis of appendicitis.
6. In acute cases the diagnosis must be based on the symptoms which were manifested during the first three or four hours.

803 Sutter Street.

Tearing Down Untimely Board of Health Placard.—In the case of the City of Memphis vs. Smythe, which was commenced by the issuance of a warrant for the arrest of the defendant for a violation of a health ordinance, the Supreme Court of Tennessee holds, to begin with, that a warrant for a fine or penalty imposed for a violation of a town ordinance is civil in character, being in the nature of an action of debt, and that consequently an appeal, after a finding of not guilty, will not be dismissed on the ground that the defendant has been once in jeopardy. The defendant in this case was a physician. The ordinance which he was charged with violating provided, under penalty by fine, that every physician should immediately report any person he might attend within the city limits sick with, or who he had reason to suspect had, diphtheria; that thereupon it should be the duty of the health officer to placard the house, with a card designating the character of the disease, and that such card should not be removed by any other than a health officer or sanitary policeman. The record in the case disclosed that, one Tuesday night, at the defendant's residence, his child was taken ill with what the defendant feared was diphtheria. The next morning he called in another physician, who, upon examination was unable to discover any symptoms of this disease, and so told the family. But notwithstanding this assurance, the defendant, still suspicious or apprehensive, after the departure of that other physician, made a telephone report to the city board of health that the child was sick with what he feared was diphtheria, adding that the other physician, who was attending the patient, did not so regard it. That (Wednesday) afternoon, that other physician called again, and repeated what he said before. Thursday afternoon, he made his last visit, when, finding the child well, or practically so, he dismissed the case. The board took no action until Friday morning, when one of its employes telephoned to the defendant that a report of the case of diphtheria at his house was required. To this the defendant replied that there was not, nor had there been, a case of that disease at his home; that his infant child had been sick, but was then entirely well. Thereafter, by order of the board, the house was placarded for diphtheria, upon discovering which the defendant tore down the placard. Then followed this action. The ordinance itself, the supreme court characterizes as a salutary one, the strict enforcement of which was essential to prevent the spread of contagious diseases. But, on the facts stated, it holds that the action of the defendant was warranted, and that he had not violated the ordinance. It says that if, on the receipt of his report on Wednesday morning, the sanitary authorities had acted by placarding the house, the ordinance would have applied. But, waiting as they did until it had been ascertained that it was not such a disease as the defendant had suspected, and the child was entirely recovered, their action, it holds, came too late. And this being so, there was no reason, the court [illegible] defendant [illegible]ould permit the placard to [illegible] se, as [illegible] if not necessary, effect [illegible] ls alike against entry [illegible]

DIFFERENTIATION IN DIABETES.

There are few diseases that have been more thoroughly studied than diabetes, and, while there has been a gradual and progressive expansion of our knowledge on this subject, the condition is still surrounded with not a little obscurity and the exact mechanism of its occurrence is not yet understood. That it is a morbid perversion of metabolism is generally agreed, as it is also that the most powerful therapeutic influence is dietetic; but we can not for the present go further than the statement that the disorder represents a defect in carbohydrate-assimilation. In a recent thoughtful paper, F. W. Pavy,[1] who has made important contributions to our knowledge on this subject, discusses some phases of differentiation in diabetes. To cases in which the sugar eliminated with the urine is derived solely from the food, he applies the designation alimentary diabetes. The carbohydrate matter of the food fails to be dealt with in the system in such a way as to be placed in a proper position for utilization, so that it appears in the blood as sugar and is thence discharged as waste material with the urine. Under normal circumstances, neither the urine nor the blood is sensibly influenced by the carbohydrate elements of the food, although the blood, like other tissues, uniformly contains a small amount of sugar.

Alimentary diabetes is attended purely and simply with the abnormal presence of dextrose in the urine, and this secretion further does not yield a color-reaction with ferric chlorid. Under other circumstances dextrose may appear in the urine, as a result not alone of defective carbohydrate assimilation, but also of abnormal proteid disintegration. In consequence of faulty metabolism, tissue-disintegration takes place, with the production of sugar, in association with other abnormal degradation products. For this latter condition Pavy proposes the designation composite diabetes. As a result of the faulty metabolism a series of products not normal to the urine appears in it, namely, beta-oxybutyric acid, diacetic acid and acetone, and the amount of these may be looked on as furnishing a measure of the extent of abnormal proteid destruction. Oxybutyric acid is, under these circumstances, found only in association with diacetic acid and acetone; and diacetic acid only in association with acetone. The beta-oxybutyric acid deflects the ray of polarized light to the left, so that the effect of its presence is to neutralize, in proportion to its amount, the deflection to the right due to dextrose. The difference between the quantitative results obtained by reduction with cupric oxid and those yielded by the polarimeter will therefore indicate the extent to which abnormal proteid disintegration is taking place. If the dextrose be fermented away by means of yeast, the levorotatory deflection noticed in the polarimeter will give the same information. The presence of diacetic acid will be indicated by the appearance of a wine-red color on addition of ferric chlorid to the urine.

The essential condition of alimentary diabetes consists in a faulty power connected with the application of the carbohydrates of the food within the system. Normally these are so utilized that no evidence of their ingestion is found in the blood or in the urine. In the presence of diabetes, however, the carbohydrates are not properly assimilated and find their way into the blood and the urine in the form of sugar. The power of assimilating carbohydrates is limited even in health, and the ingestion of an amount beyond that will be followed by glycosuria, so that the diet must be adjusted accordingly. The characteristics of alimentary diabetes consist in the control of the glycosuria by the exclusion of carbohydrates from the food and the absence of beta-oxybutyric acid and diacetic acid from the urine. To ascertain the degree of severity the assimilative power must be estimated by determining the largest amount of carbohydrates that can be taken without inducing glycosuria. Under favorable conditions it will be found that gradually increasing amounts of carbohydrate will be tolerated, and this will be indicated by continued absence of sugar from the urine, and also by loss in weight; and increase in the amount of carbohydrates to a point yet within the assimilative capacity of the organism will now neutralize the loss of weight. Alimentary diabetes is unattended with any liability to the supervention of the fatal coma that occurs in cases of composite diabetes as a result of the activity of toxic products resulting from tissue-disintegration. The intensity of the symptoms is proportionate to the amount of sugar in the system, as indicated by the quantity appearing in the urine. This will be shown by amelioration and gradual disappearance of the symptoms with the subsidence of the glycosuria when the carbohydrates are diminished or withdrawn.

The case acquires a serious aspect when the alimentary is converted into composite glycosuria. This takes place more readily in early than in late life, and in neurotic individuals, and as the result of hereditary tendencies. Under the morbid influence in operation the tissues melt down into the unexhausted products that escape as waste matter with the urine. The degree of emaciation may become extreme. The coma by which life often is terminated is the result of a true autointoxication. The nature of the intoxicant has not yet been determined with certainty, although it has been thought to be beta-amido-butyric acid.

PRIMARY ENDOTHELIAL HYPERPLASIA OF THE SPLEEN—A DEFINITE AND DISTINCT DISEASE.

Many of the diseases of the spleen and of the lymph-glands are exceedingly obscure in their nature. There are leukemia and pseudoleukemia, whose clinical picture and anatomical changes are familiar enough, but of the real nature of these processes we are wholly in the dark. The recent report by Crowder[1] of a peculiar form of chronic hyperplastic glandular tuberculosis simulating pseudoleukemia to perfection, indicates that chronic glandular hyperplasias of a pseudoleukemic type may be of a tubercular character perhaps oftener than now expected. The conditions that determine the peculiarities of this form of glandular tuberculosis, whether connected with the bacillus or with the soil, baffle all explanation at this time. The affection variously described as splenic anemia, Banti's disease or splenic pseudoleukemia is characterized by considerable enlargement of the spleen, the changes being essentially of a chronic interstitial character. That this disease is intimately connected with splenic lesions would seem to be demonstrated by the cures reported by Italian physicians to follow splenectomy; but of the essential nature and the cause of the malady nothing is known.

And now comes Bovaird[2] with the description of two remarkable instances in children of a primary enlargement of the spleen dependent on an extensive endothelial hyperplasia, judging from the histologic study of the spleen in the fatal case. The patients were sisters, the first signs of the disease appearing at the ages of 2 and 3 years, the latter dying at 13 from splenectomy. Bovaird sums up the symptomatology as follows, based on his own cases and on the reports of similar cases—mostly females—by Gaucher, Collier and others: Slow and progressive enlargement of the spleen, beginning in childhood—2d to 7th year—with a secondary enlargement of the liver and simple anemia. Softening of the gums, with oozing of the blood, epistaxis, cutaneous hemorrhages and icterus have been observed, the first being quite constant. The mechanical effects of the splenic enlargement may be the cause of pain, gastro-intestinal disturbances, dyspnea, dysuria and cramps in the legs. In Bovaird's fatal case the spleen weighed 12½ pounds, the total weight of the child being 75 pounds. The form of the spleen in general was that of the normal organ.

The clinical differentiation of cases of the type described by Bovaird from splenic anemia—Banti's disease—seems at present impossible, but the anatomic lesions of the two diseases differ. As already indicated, the splenomegaly of Gaucher and Bovaird is dependent on a marked endothelial hyperplasia which may be associated with like changes in the retroperitoneal and mesenteric lymph-nodes and the connective tissue of the liver. These alterations are well illustrated in Bovaird's drawings. On the cut surface the spleen and certain parts of the liver showed numerous firm white or yellowish-white areas corresponding to large irregular spaces filled with large cells. The areas in the liver are regarded as developing from the endothelium of the lymph-spaces and not as metastases. Iron pigment was present in large quantities in the lymph nodes and the liver. Bovaird's view that the process is not an endothelioma—Gaucher speaks of his case as an epithelioma—is supported by such authorities as Cornil and Birch-Hirschfeld. The nature of the affection—the entity of which seems established—is beyond our present ken. As yet bacteriologic studies do not seem to have been made. They are indicated whatever the results therefrom might be. The reports of cases like these are inducive to careful study of that enigmatic organ, the spleen.

CHANGES IN THE MOTOR GANGLION-CELLS ASSOCIATED WITH PERIPHERAL NEURITIS.

Whether or not the conception of the neuron as applied to the nervous system can be accepted without qualification in its present form, there is no doubt that it has been a great help in clarifying our physiologic and pathologic notions in this field of observation. Viewing the nerve-cell and its processes as one continuous whole, it can be readily understood how a lesion in any part of it will give rise to similar clinical manifestations. Further, as the nutrition of the cell is dependent on the integrity of the body, through its nucleus, it must be evident that the most remote part will be the most susceptible to degenerative changes. Disease of the cell will necessarily be followed by disease in its processes, but it has not been sufficiently appreciated that disease in the latter may be attended with changes in the former. It has been observed that sometimes perfect recovery takes place, while at other times cells undergo atrophy and disappear.

Evidence in confirmation of this latter fact is afforded by the results of a microscopic study lately made by Hunter[1] of the motor ganglion-cells, in addition to the peripheral nerves, in five cases of peripheral neuritis, four of alcoholic origin. It was found in three of the cases that, although there was but slight loss of power in some of the muscles, there was marked inflammation of the corresponding nerve. This disparity may be explained on the supposition that changes in structure precede alteration in function. In three of the cases also the motor ganglion-cells exhibited chromatolytic changes corresponding more or less closely to those found in animals following injury to peripheral nerves. In [illegible] case the appearances, while presenting a [illegible] the normal, could not be decided to be [illegible]tive or regenerative. The changes [illegible] situated about the nucleus, while [illegible] periphery itself seemed [illegible]

---

1. New York Med. Jour., Sept. 15, 1900.
2. Am. Jour. of Med. Science, October, 1900.

1. Lancet, Aug. 25.

In all the medial group of cells in the anterior horns were practically unaltered. In the dorsal region, where the lateral cells were fused with the medial groups, the former were quite normal, but in the cervical and lumbar enlargements the degenerative changes were most marked in the postero-lateral subgroup. In two cases the number of ganglion-cells appeared diminished. A deposition of yellow pigment was found to some extent in nearly all of the ganglion-cells, as well in those that appeared to be healthy as in those undergoing chromatolytic change, completely filling some and occupying half of the cell-plasma in the majority. This pigmentation takes place at the expense of the Nissl bodies, causing fragmentation of the chromatic granules. It is thus a variety of chromatolysis, and if the chromatin-granules represent the functional potentiality of the cell, either in form of nutrition or as energy, or both, the destruction of the granules must be looked on as a degenerative change. This is attended with a corresponding alteration in the vessels, in the walls of the smaller of which colloid degeneration was found throughout the nervous system in all of the five cases examined.

As a result of the foregoing observations, it may be concluded that the presence in the blood of toxic substances capable of exerting a deleterious influence on the peripheral nerves affects not alone the neuraxon, but all parts of the neuron.

MEDICAL INSPECTION OF SCHOOLS.

Last January the medical inspection of school children was put in operation by the school board of Chicago. While it proved satisfactory, certain politicians conceived the idea that the few thousand dollars annually expended in this direction could be used for a better purpose—better for the politician. Accordingly, a feeling was created against the employment of physicians as inspectors, and for a time it seemed as if the efforts of these would-be economists would succeed. But recently most definite results have been seen, and several instances have occurred wherein timely discovery of contagious disease in the schools and quick isolation prevented an epidemic. Most of the newspapers have favored the work from the first and have defended the medical inspectors in the efforts to prevent epidemics among the school children. The Chicago *Times-Herald* of October 22 editorially says:

> The record of the work accomplished by the medical inspectors in preventing the spread of contagious diseases in the Chicago public schools should have greater weight in determining the action of the board with reference to continuance of the system than any arguments that may be advanced along the line of retrenchment or economy. The value of the work to the whole community should also overweigh any objections from parents who may have suffered some personal inconvenience from the inspection. A statement of the work accomplished by the medical inspectors shows that during three and a half months of the last school year 76,000 examinations were made and 4539 cases of contagious disease were discovered and excluded from the schools. Since September 17 of the present year 7249 examinations have been made and 510 contagious cases have been excluded. The argument of economy can not have much force against such a showing of preventive efficiency as this. If the medical inspection system has kept the schools from spreading epidemics it is worth many hundred times the cost of its maintenance. Indeed it would be difficult to calculate the money value of such a service. The fact is the medical inspection system should not be disturbed under any pretext whatever. Its cost is trifling compared to the benefits that accrue to the community through the inspection. It would be a very short-sighted policy to cut off this safeguard against epidemics in the schools on the score of economy, while large sums are being expended for the non-essentials of a common school education. Medical inspection in the public schools of a city of this size is absolutely essential as a measure of public safety.

There can be no doubt whatever that, as at present managed, the close intelligent watching of the physical condition of children in the crowded school-buildings of a large city will be a power in preventing epidemics. It is shutting the door before, not after, the horse has escaped; the ounce of prevention rather than the pound of cure.

PHYSICIANS NOT LIABLE WHEN THEY ACT IN GOOD FAITH.

The Supreme Court of Massachusetts, in full bench, has given out a decision that is of interest to medical men. It holds that physicians under the Massachusetts statutes are not liable for negligence in erroneously certifying a person insane or inebriate, provided they do so in good faith and without malice. Even if their examination was a careless one their action was not the proximate cause of the commitment, as a judge must, under the statutes, determine that; and, secondly, they should, in accordance with public policy, be like other witnesses, considered privileged and protected against liability as long as they act in good faith and without malice. The opinion was a majority one, but, while not unanimous, it is sufficient to protect Massachusetts physicians from vindictive damage-suits and may be a valuable legal precedent elsewhere.

PHYSICIANS AND THE HALL OF FAME.

In our last issue, notice was taken of the omission of any medical names in the list of those selected for the so-called Hall of Fame. As there are but two medical men on the jury of award, it is quite possible our profession, commanding thus only 2 per cent. of votes, will scarcely have a fair show even in a future election. It has been suggested that an expression of the general consensus of opinion of the medical profession might have some influence, and it appears to be a good one. If for example the AMERICAN MEDICAL ASSOCIATION would pass a resolution naming certain ones, in its opinion, worthy of the honor, its action might have weight, even with the laymen on the jury. The suggestion is a practical one and worthy of consideration. It would be no honor to the Hall of Fame if worthy members of a profession which has done much for humanity, were willfully or even ignorantly omitted from its rolls.

JUDICIAL ARROGANCE AND IGNORANCE.

The judge, in a recent noted trial in which the accused was reported ill, is said to have given out, among other remarkable utterances, the following: "I could tell nothing by going to see the defendant as to his condition, but I do not want his physician or any other physician to fill him full of opiates and keep him in that condition, and that is a matter which must be looked after." This is an expression of opinion after an admission of ignorance, and a very injudicial slur as to the integrity of members of our profession. One thing is certain, no honorable and self-respecting physician would let a judge dictate to him in matters altogether out of the judicial sphere; prescriptions and treatment of the sick are not within the jurisdiction of the court. "In the sick room," as the Louisville *Post* remarks, "the physician is supreme," and if not he should be, judges to the contrary notwithstanding. Even a man accused of crime has rights as a patient and a human being beyond the jurisdiction of the court.

DR. JOHN CONTEE FAIRFAX.

In a recent issue we gave a three-line notice of the death of a member of the medical profession whose decease has been made the subject of half-column editorial notices in our two leading British contemporaries. Dr. John Contée Fairfax was in this country simply an American citizen, than which there is no higher rank; though not a British subject, in Great Britain he was officially recognized as sharing alone with Lord Lister the honor of membership both in the medical profession and the British peerage. This fact is noteworthy, as well as that of his descent from the parliamentary General Fairfax of that epoch of English history most familiarly known to us as "Cromwell's times," and from the Lord Fairfax who was Washington's friend and early patron. Dr. Fairfax appears to have been a very estimable gentleman, and while more of a landed proprietor than an active medical practitioner, the only title he cared to go by was that of Doctor, acquired as a graduate of the University of Pennsylvania. It is worth noting also in this connection that the history of the Fairfax family is said to be the foundation on which Thackeray built his celebrated novel of "The Virginians."

OBJECTIONABLE DRUGGISTS' CIRCULARS ABROAD.

The *British Medical Journal* states that English practitioners are seriously annoyed by objectionable pamphlets mailed to them by American drug firms, and that in the case of one particularly disgusting instance the postal authorities of the two countries have been called on to intervene. It very properly requests, however, that any of its readers sending these objectionable pamphlets with their complaints should do so in the original wrappers, as it has a suspicion that some of the pamphlets are really posted in London. It is not pleasant to hear that American druggists send disreputable literature abroad, and we trust that what they send is bad only in a medico-ethical point of view. The American postal laws are rigid as to the transmission of immoral publications through the mail; it would be a simple matter to call the attention of the authorities to any such emanating from this side of the Atlantic and would speedily put an end to their circulation. It will possibly be found that the majority of such received in Great Britain also originated there; the fact that they contained testimonials from persons holding British qualifications suggests that this probably is the case. We have British-labeled frauds in this country; it is quite likely they have their counterparts there.

AN UNAPPRECIATED JOKE.

Some time ago a Denver daily paper made some comments on what was either an abnormal temporary condition or a gross error of statistics in regard to masculine mortality in the state of Colorado. The Journal editorially noticed them, in what was intended as a semi-facetious way, remarking on the possibility of the Centennial state becoming in the future an "Adamless Eden" and suggesting as the only possible explanation the contiguity of Utah with its polygamous traditions of the past. It scarcely seemed probable at the time that the tone of the article would permit of its being taken seriously, but such seems to be the case. It has traveled over two continents, and though slightly disfigured is still in the ring. The Journal has in this repeated the experience of Mark Twain, who found that he could not in the most innocent and transparent way play hob with the probabilities and possibilities without some one accepting it all as gospel truth. The safest course is in all such cases to follow the example of another noted humorist, who early recognized this weakness of human intelligence and often ended his lucubrations with the commentary: "This is a goak." For the benefit of all such literally-minded individuals The Journal here expresses its opinion that there is no immediate danger of Colorado losing its male population, or reverting to conditions where, as an English contemporary naively remarks, "social conventions may have to be modified." It will endeavor to be more careful in the future, and, if necessary, will label its jokes.

NEW POINTS ON COLOR-BLINDNESS.

It has usually been held that all except about 3 or 4 per cent. of mankind possess normal color perception, that is, that they agree in seeing colors alike in the way we consider them to normally exist. It has been admitted that very slight variations might exist beyond these limits, but that they are too insignificant to require consideration. Unlike other peculiarities of vision, color-vision is esteemed as practically uniform in the mass of mankind. According to recent studies by Prof. Ogden H. Rood, whose former work on colors is well known, there is really no such uniformity, and individuals vary as much in this as they do in the other niceties of visual perception. From an editorial abstract of his work in the *Post-Graduate* for October, we learn that with the use of the Flicker photometer, a new instrument for measuring color-perception, Rood finds that no two agree in this respect, and that the variations are quite striking even in persons ordinarily considered as normal in their color-vision. Taking the average of eleven individuals selected for the experiments as the normal figure and reckoning it as 100, he found only three of them whose perception reached the average standard for red, three for violet-blue and five for green, and that the defects varied for these respective colors from 1 to nearly 20 per cent. The females varied from the standard as much as the males as regards green perception, though exceeding them as regards the other two colors. The number of cases examined in this study is small, but they were carefully selected and observed, and justify the claim of Professor Rood that no man or woman is thoroughly qualified to do color work until his or her color-vision has been tested, and apparently this will have to be done by such an apparatus as the Flicker photometer, with which he detected these variations. The question of color-blindness is one that calls for considerable study even yet, not merely for its scientific interest, but also on account of the practical points involved. Professor Rood's results will suggest some further investigation of the problems of color defect, with special reference to railway and steamship service, and may possibly lead to more perfect and satisfactory methods and standards than those now in use.

Medical News.

CALIFORNIA.

Sacramento reports a death-rate for September of 16 per 1000 per annum.

Los Angeles reports 117 deaths during September, 25 of which were due to tuberculosis.

Dr. Asa Clark has been reappointed medical superintendent of the State Hospital for the Insane at Stockton.

Dr. Samuel O. L. Potter has resigned from the board of trustees and from the chair of theory and practice of medicine and clinical medicine in the College of Physicians and Surgeons of San Francisco.

The Merritt Hospital, Oakland, will now be built. The Supreme Court of the United States has sustained the decision of the lower court and the $500,000 devised by Mrs. Catherine M. Garcelon for this purpose is thus made available.

The Student Guild of Stanford University has funds in hand and will build a hospital for the use of students of the institution. The authorities of the university will provide for the maintenance of the hospital.

DISTRICT OF COLUMBIA.

The commissioners of the District have appointed a commission, of which Health Officer Woodward is a member, to consider all proposals for the sale of land for the proposed municipal hospital.

Major John Van R. Hoff, who was recently ordered to China as chief medical officer of the United States forces there, has been relieved from duty and ordered to San Francisco.

The Freedmen's Hospital, during the fiscal year, treated 8744 patients in the wards and dispensary. The percentage of mortality was 6.37. During the year 634 operations were performed, with a death-rate of 1.1 per cent.

The board of medical examiners of the District reports that during the year ended June 30, 1900, 95 applications for license to practice were received. Of these, 22.92 per cent. failed. Licenses for midwives were applied for in nine cases and a certificate issued in each case. It asks for a suitable compensation for its members, stating that the average amount received by members of the board has been only $22.84 for the regulars, $1.76 for the homeopaths and nothing for the eclectics.

ILLINOIS.

The Springfield Board of Health has decided to ask the city council to allow an appropriation sufficient for the erection of an isolation hospital, for which there is urgent need in the city.

ORGANIZATION IN ILLINOIS.

The committee on medical legislation appointed by the Illinois State Medical Society has issued a circular-letter, from which we quote a part: From our correspondence with similar committees in other states and from action taken at the last meeting of the American Medical Association, we believe that there is a general awakening of the profession to the necessity for more active and harmonious work. The New York State Medical Association has been recently entirely reorganized on what is known as the Connecticut plan. This plan, in brief, makes membership in the local society include membership in the state society. The fees are all paid to the local society, thus the local society is made the basis of the whole organization of the state. We believe this to be the correct principle of organization. Your committee is thoroughly convinced that if Illinois is to maintain its place in the first rank we must immediately improve our medical organization. Instead of having a state society which only embraces a part of the local societies of the state and only a few hundred of the many thousand regular practitioners, we must effect an organization which will practically embrace all our regular practitioners. We are now addressing every member of the state society on this point and asking them for suggestions and assistance in changing the present conditions. Why is it that the majority of the regular practitioners in the state have not allied themselves with the state society? The committee sees plainly that they will be unable to secure or maintain the most desirable legislative measures without a more complete organization behind them. Among the questions which are demanding solution in our state we would suggest the following: A thorough organization of city, county and state boards of health with proper relations to each other; more adequate sanitary laws, especially those relating to schools, manufactories and quarantine; to secure legislation to protect against tuberculosis and other preventable diseases; to protect against vicious legislation, for example, antivivisection and antivaccination; to protect from blackmailing, and to protect against unjust malpractice suits; to secure proper recognition of expert testimony; to protect the sick from quacks and charlatans; to protect and improve the medical-practice act and to secure a special board of medical examiners, aside from the board of health; to secure proper regulations for the protection of drinking-waters, and in fact to aid in securing just and impartial legislation whenever and wherever needed; to secure equitable medical laws throughout the United States, with some practical form of reciprocity between states; to secure the appointment of reputable and honorable medical men wherever public services of physicians are required throughout the state. These and many other questions are demanding the attention of the profession. We should be thoroughly alive to their importance and realize that the only way to secure any needed enactments or suitable appointments is through harmonious organization of our profession. We must all be willing to submit to the will of the majority. We have all, no doubt, been chagrined to hear members of the legislature say that the only thing which stands in the way of securing desirable medical legislation is lack of harmony in the profession. We should remove the cause for this now just criticism. . . . We are directed by the state society to organize the profession along these lines, and hope to have your assistance in getting in touch with the public-spirited physicians of your locality. The profession must be organized to protect the interests of the sick as well as its own interests.

Chicago.

Dr. S. C. Plummer returned, October 23, from his summer in Europe.

The medical inspectors, on October 22, closed four rooms at the D. S. Wentworth School on account of diphtheria discovered among the scholars, and one room at the McCosh School on account of scarlet-fever.

The Illinois Home for Epileptics has moved to its permanent location, 3240 Lake Park avenue. The home is a charitable institution and is open at all times for the reception of emergency cases.

Dr. M. N. Regent, now awaiting sentence for conspiracy to defraud, was refused a new trial by Judge Brentano, October 17.

An epidemic of matrimony is raging among Chicago physicians. Dr. A. N. J. Dolan was married to Miss Georgiana Sexton, on October 10; Dr. Charles Heller to Miss Rosie Greenhoot, October 16; Dr. Charles F. Weir to Miss Eleanor Reeves, October 18, and Dr. Louis A. Mueller to Miss Louise Wilke, October 19.

The Senn Memorial Room at St. Joseph's Hospital, which has been completely furnished by Dr. Nicholas Senn, and in addition endowed for $10,000, was formally opened October 16. During the life of the donor he will have the privilege of designating patients to occupy the room.

The banquet to be given in honor of Dr. Christian Fenger on Nov. 3, at the Auditorium Hotel, promises to be an interesting affair. Dr. C. A. L. Reed, president of the American Medical Association, will be toastmaster; Dr. W. W. Keen, Philadelphia, will make the speech, presenting the loving cup. Speeches are expected from Dr. Charles A. Wheaton, St. Paul; Dr. Charles B. Nancrede, Ann Arbor; Dr. E. S. Rickets, Cincinnati; Dr. W. H. Earles, Milwaukee; Drs. Nicholas Senn and William E. Quine, Chicago, and others. As the attendance from Milwaukee, St. Paul, Minneapolis and other nearby cities is expected to be large, the committee would like to know as nearly as possible the number that may be present. Dr. W. A. Evans, Chicago, is Chairman.

HEALTH DEPARTMENT.

Only 385 deaths were recorded in the bureau of vital statistics during the week ended October 20. *This total furnishes an* annual death-rate of 11.81 per 1000 of the United States census figures of population, 1,698,575—the lowest October weekly mortality-rate ever recorded in Chicago, and with one exception the lowest mortality of any week of 1900. As compared with the previous week, only deaths from pneumonia show an increase; deaths from convulsions and from violence were stationary; while deaths from the impure-water diseases, including typhoid fever, from bronchitis, heart disease, nervous diseases, cancer, diphtheria and scarlet fever show the greatest numerical reduction in the order given. During the first twenty days of the month *the daily deaths averaged 58*—a figure which, if maintained during the remainder of the month, would make the total October mortality only 1793, and an annual rate of less than twelve and one-half per 1000. During the twenty-five school days since September 7 the inspectors have examined 9770 ailing children in the public schools, and 694 of these were found to be suffering from diseases liable to spread to other pupils with whom they were in contact. Among these were 16 cases of diphtheria, 17 of scarlet fever, 17 of measles, 30 of whooping-cough, 36 of chicken-pox, 126 of tonsillitis, 13 of purulent sore eyes, 123 of impetigo contagiosa, 145 of *pediculosis*, 25 of *ring-worm*, 24 of eczema and 47 of other "catching" diseases. With the lowering temperature of the autumn days—necessitating the closing of doors and windows and consequent exclusion of fresh air—the number of ailing children increases, as will be seen by these figures of examinations and *exclusions:* Week ended September 21, ailing pupils examined, 801, excluded, 97; September 26, examined, 1939, excluded, 112; October 5, examined, 1998, excluded 168; October 19, examined, 2521, excluded, 184. Another and very potent cause of this increase is the association of the children themselves in the too-often badly ventilated class-rooms and assembly-halls of the average schoolhouse. What is known as the "school diffusion" of contagious diseases, especially diphtheria, scarlet fever, measles and whooping-cough, is now well understood and it is this that makes school inspection of so much importance and utility in the prevention of the spread of the communicable diseases of childhood. The total deaths from all causes were 385; for the corresponding week of 1899, 495. Of males, 196, and of females, 179, died. Under 1 year, 78 died; between 1 and 5 years, 45, and over 60 years, 74. The principal causes of death were: Consumption, 45; acute intestinal diseases, heart diseases and pneumonia, each 35; nervous diseases, 25; violence, 19; cancer, Bright's disease and diphtheria, each, 16; typhoid fever, 6; scarlet fever, 2, and suicide, 3.

INDIANA.

Dr. Charles H. Eckert, Marion, was thrown from his buggy and severely injured October 5.

Dr. Henry A. Fink, South Bend, had a rib broken and was otherwise badly bruised in a runaway October 8.

Dr. James W. Stewart, Logansport, was married to Miss Mamie Magee at Benton Harbor, Mich., August 16. Dr. and Mrs. Stewart have gone to Europe and expect to remain for a year.

IOWA.

Dr. R. U. Chapman, Des Moines, has returned from a tour of Europe.

Dr. Harry P. Engle and Miss Shirley Mann, both of Newton, were married October 3.

Waterloo business men have organized a hospital association and propose to establish a hospital.

The Sioux City College of Medicine held its opening exercises on October 3. Dr. George Park delivered the opening address.

The *Austin Flint Medical Journal* of Mason City will be edited and published by Dr. F. G. Murphy, Dr. T. T. Blaise retiring from the journal. The space heretofore occupied by translations will be given to original articles from the Iowa profession.

KANSAS.

Dr. A. Hudson Hepler, Fort Scott, was married to Miss Martha Jessie Polsgrove, at Fort Worth, Tex., October 10.

Dr. Russell Phillips, Leavenworth, was married to Miss Theresa Rossington, Topeka, at her home in Topeka, Oct. 10.

KENTUCKY.

Dr. Frank Lapsley, Paris, has returned from a summer tour of Europe.

Dr. Archibald H. Barkley and Miss Roberta F. Johnson, both of Lexington, were married, October 17.

Dr. Redin Kirk has returned to Louisville after service in the medical department of the army in Porto Rico and the Philippines.

The State Board of Health has issued a special illustrated circular with reference to the treatment of smallpox and precautions against it. Vaccination and revaccination is urged. It states that "within the past two and a half years this disease has prevailed more or less extensively in 81 of the 119 counties of Kentucky." "It should also be constantly borne in mind that there are no such diseases as 'elephant itch,' 'African itch,' 'army itch,' or 'Cuban itch,' and that in all of the many instances investigated by our experts, where the disease was ignorantly reported under these and other similar misleading names, they were found to be cases of genuine and unmistakable smallpox."

MARYLAND.

The Board of Medical Examiners of Maryland will hold the semi-annual examinations at the rooms of the Medical and Chirurgical Faculty, November 7, 8, 9 and 10.

The semi-annual meeting of the Medical and Chirurgical Faculty of Maryland will be held at Towson, Baltimore County, in November. One of the most important subjects to be discussed at this meeting is the proposed amalgamation of all the medical societies in Baltimore into one organization dominated by the Faculty.

Baltimore.

The deaths for the week ending October 20 were 182, an annual death-rate of 17.49 per 1000—whites, 15.61, colored, 28.66. Of these, 79 were un[illegible] years of age. Typhoid fever caused 3 deaths, [illegible] culosis 26, [illegible] r 7, pneumonia 8, ch[illegible] 's dis[illegible] births reported were [illegible]; of scarlet [illegible] 8, [illegible] cough, 3.

At the [illegible] Hebrew H[illegible]

were received. Two hundred and sixty-four patients were admitted during the year. A large number of consumptives were treated in the new wing devoted to that disease; and 6043 patients were treated in the dispensary.

MASSACHUSETTS.

Dr. Francis D. Donoghue, Boston, was married on October 15 to Miss Marian Fiske, of Malden.

Dr. Herbert S. Hayford, Quincy, was married to Miss Clara L. Roe, at her home in Whitestone, L. I., October 18.

Dr. Joshua F. Lewis, Malden, has been appointed by the State Board of Charity, superintendent of the adult poor of the state.

The City Hospital is about to erect a relief station in Haymarket Square. This has been made possible by the bequest of the late Thomas T. Wyman, amounting to about $120,000. The building will be three stories high, with basement, and have an area of 120x60 feet.

MICHIGAN.

During September, 68 cases of scarlet fever and 14 cases of typhoid fever were reported in Grand Rapids.

The Union Benevolent Hospital at Grand Rapids reports that during the fiscal year just ended, 504 patients, 253 medical and 251 surgical, were admitted. Operations were performed on 242 patients with 9 deaths.

The State Board of Registration in Medicine completed its first year on October 10. During this time it has examined 6000 applicants, about one-third of whom were rejected. The board recognizes only 37 colleges in America as coming up to the standard required.

The resignation of one house-physician in the Emergency Hospital, Detroit, is said to be due to an unusual curtailment of the authority vested in that office. It is rumored that the other members of the house staff will leave the hospital soon.

The secretary of the State Board of Health believes that life and treasure might be saved the state, were a law enacted placing the determination, from time to time, of the question of what diseases are to be considered communicable, in the hands of a sanitary body which shall be charged with the duty of publishing each year a list of the diseases then known to sanitarians to be dangerous to public health and therefore required by law to be reported and restricted.

MINNESOTA.

Of the forty-five who applied to the State Board of Medical Examiners for examination, on October 11, thirty-two were given licenses to practice.

Quintuplets, all boys, weighing in the aggregate 30 pounds, were born to a woman in Marnis Home, October 12. She has been married only seven years, but had had already 11 children, all of whom came in twos or threes, with one exception.

St. Paul furnished one, and Minneapolis three, of the physicians cited to appear before the State Board of Medical Examiners to show cause why their licenses should not be revoked. All the cases were continued until January, 1901.

MISSOURI.

A banquet was tendered to Dr. I. N. Love, who is leaving St. Louis to settle in New York, on Oct. 15, by his medical friends in St. Louis, at the Southern Hotel, at which a beautiful silver loving-cup, engraved with the names of the donors and a likeness of Dr. Love, was presented to him. The formal presentation was made by Dr. G. Wiley Broome, who, in the name of the medical men of the city, expressed regrets at Dr. Love's departure and wishes for his success in his new venture and his new home. Dr. C. H. Hughes acted as toastmaster, and Dr. Love made a suitable response.

NEW HAMPSHIRE.

Dr. Howard N. Kingsford, Hanover has been appointed director of general athletics at Dartmouth College, and medical director of the college football team.

The jury in the case of O'Toole against Dr. John Ferguson, Manchester, for damages on account of permanent injury alleged to be due to the defendant's negligence and lack of skill. has rendered a verdict for the defendant.

The Woman's Hospital Aid Association, Concord, at its annual meeting, elected the following physicians on its board of officers: Ellen A. Wallace, Manchester, vice-president and consulting physician; Julia Wallace-Russell, Concord, corresponding secretary and physician in charge; Granville P. Coun, Ferdinand A. Stillings and Charles P. Bancroft, Concord, consulting physicians and surgeons; Mary A. Danforth, Manchester, and Marion L. Bugbee, White River Junction, Vt., associate physicians, and Dr. Arthur K. Day, Concord, pathologist.

The next examination for licenses to practice medicine in the state of New Hampshire will be held at the state house, Concord, on Dec. 11 and 12, beginning at 8 a.m. All unlicensed physicians not in practice in the state on and before March 16, 1897, must pass the examinations in order to receive a license to practice legally their profession. All information regarding the examination will be cheerfully given by the Department of Public Instruction, or by the regent of the State Boards of Medical Examiners, State Library, Concord.

NEW JERSEY.

Dr. Howard V. Merrell, Plainfield, was married to Miss Elizabeth Huntington Bridge, of Brooklyn, Oct. 3. Dr. and Mrs. Merrell will reside in Meadville, Pa.

In the suit brought by Peter Jones against Drs. Thomas A. Skillman and Thomas V. Meacham, New Brunswick, for wrongful commitment to Trenton insane asylum, the jury brought in a verdict against Dr. Skillman, awarding the plaintiff $50 damages, but non-suited him in the suit against Dr. Meacham.

The Camden physicians are seconding the board of health's efforts to induce the city council to establish a municipal hospital for contagious diseases. Dr. Paul N. Litchfield has presented a petition signed by fifty-six members of the profession, praying for the establishment of such an institution. Dr. Henry H. Davis, president of the board, inaugurated the movement several months ago and says the city is certainly in need of one.

NEW YORK.

The committee of arrangements for the 1901 meeting of the American Electro-Therapeutic Association, at Buffalo, consists of Drs. Henry R. Hopkins, William W. Potter and Julius Ullman.

The Child's Hospital, Albany, has made the following changes in its visiting staff: Drs. Alvah H. Traver, Charles E. Davis and Arthur W. Elting were made attending surgeons, and Drs. Andrew MacFarlane and Henry L. K. Shaw, attending physicians.

Dr. Simon Baruch, New York City, has been awarded a silver medal at the Paris Exposition for his efforts in behalf of the establishment of public baths.

THE CRAIG COLONY FOR EPILEPTICS.

The Board of Managers of the Craig Colony for Epileptics, at Sonyea, held its seventh annual meeting Oct. 9, and organized for the following year by re-electing Dr. Frederick Peterson, New York, president, and Mr. H. E. Brown, Mt. Morris, secretary. The medical superintendent, Dr. Wm. P. Spratling, reported 612 patients in the Colony on October 1. A gain of 234 was made during the year. The total capacity of the Colony is 840, and it is expected that it will have that number by July 1, 1901. It was decided to ask the legislature for $169,000 for new buildings and other improvements, and for $125,000 for maintenance. The superintendent called attention to the fact that 36 out of 612 of the inmates are suffering from tuberculosis, and recommended that suitable wooden barracks be constructed so that these patients might be isolated. He also called attention to the great necessity for providing better means of transportation on the Colony and advocated the construction of a trolley system, the power for which already exists at the Colony. The per capita cost for maintenance in 1898 was 300; in 1899, 216, and in 1900, $172. A resident pathologist, at $2,500 a year with maintenance, will soon be appointed, for whose use a laboratory has been built and equipped.

OHIO.

Dr. Edward R. Henning, West Liberty, has returned from a two years' tour of Europe.

Dr. Martin Stamm, Fremont, has been appointed chief surgeon of the T., F. & N. Electric Railroad Company.

Dr. W. W. Seeley and family, Cincinnati, sail for Europe in November. They expect to spend the winter in Egypt.

Licenses to practice were granted on October 8 to 12 persons who took the examination of the State Board of Medical Examination and Registration at Columbus.

Two women, one a "cancer doctor," of Cincinnati, the other a specialist in "female diseases," of Sardinia, who had neglected to register, in accordance with the law of the state, were arrested at Blanchester, October 4.

Dr. Harry L. Gilchrist, Cleveland, who has been serving as an acting assistant-surgeon in the army in the Philippines, has passed the examination for admission to the medical department of the army.

The house physician of St. Vincent's Charity Hospital, Cleveland, the Sisters of Charity, Mother Superior and Ignatius F. Horstmann are defendants in a suit for $10,000 damages entered September 29 by a patient who claims that she was burned by hot-water bags while in narcosis after operation.

PENNSYLVANIA.

Mercy Hospital, Wilkesbarre, has elected Drs. Samuel M. Wolfe and Edward C. O. Wagner, members of the surgical staff.

The Lancaster General Hospital, has been offered $5000, provided the institution raises a similar amount.

The quarterly changes in the attending staff of the Johnstown Memorial Hospital are Dr. George W. Wagoner, attending surgeon, vice Dr. Alfred N. Wakefield, term expired, and Dr. William E. Matthews, attending physician, vice Dr. John C. Sheridan, term expired.

Seven cases of typhoid fever are reported from Ambler and more than 200 cases from Bolivar and the surrounding country, attributed to polluted drinking-water.

E. P. Wilbur, formerly president of the Lehigh Valley Railroad, has donated $10,000 to St. Luke's Hospital, of South Bethlehem, the income of which is to be devoted to the support of the children's ward. Samuel Thomas, Catasauqua, will build an operating ward for the hospital to cost $10,000.

The State Quarantine Board has decided to improve the facilities at Marcus Hook, near Philadelphia. Two new detention barracks will be erected for the accommodation of 400 patients. A tug boat for boarding vessels and for a floating disinfectant plant will also be built. It was decided to lift the quarantine restrictions on coast vessels from points north of St. Mary's River, Florida, from November 1 to March 31.

Philadelphia.

The Philadelphia Medical Club gave a reception October 26, in honor of Dr. Maurice H. Richardson, Boston.

The number of deaths which occurred for the week ending October 20 was 366, an increase of 28 over the previous week, and a decrease of 18 over the corresponding period of last year.

The committee recently appointed by President Potter, of Jefferson Medical College, to establish a clinical laboratory in honor of Dr. J. M. Da Costa, met October 13 and appointed a sub-committee to prepare a circular letter to be distributed setting forth the need of such an institution.

The city council committee on Charities and Correction, recommended to the finance committee an appropriation of $130,000 for the erection of new buildings as additions to the Philadelphia Hospital.

TENNESSEE.

The Memphis Hospital Medical College will begin its twenty-first annual session November 1, 1900.

The State Board of Pharmacy met in Nashville, October 17, and instructed its attorney to draw up a bill to be presented to the next legislature providing for the regulation of the selling of cocain in Tennessee. The use of this drug among the lower classes, especially negroes, has increased within the past few months at an alarming rate, and all efforts to prevent the sale of the drug have been unavailing. Nashville, Memphis, Chattanooga and Knoxville have passed ordinances providing that the drug can be purchased only on a physician's certificate, but this fails to meet the requirement. There are thousands of cocain sniffers in the state.

The State Board of Health held its semi-annual session in Nashville, October 15. Secretary Albright submitted a report in regard to the smallpox condition of the state. The report stated that since the last meeting of the board the disease had appeared in thirty-one counties. At the present time, however, the disease exists in a mild form only in six counties. In all these, with the exception of Maury, the regulations of the State Board was being observed. There are in the state at present only about twenty-five cases. In Maury county, it was stated, the board had met with a flat refusal from the county board when called on to assume charge of a case which appeared at Mount Pleasant. The reason assigned was that the county could not afford a repetition of the heavy expense incurred in stamping out the disease last year. After much discussion, a committee was appointed to go to Maury County and see if something could not be devised to prevent the spread of the disease. The general health of the state was reported as good.

CANADA.

The medical and surgical staff of the Victoria Hospital, Halifax, has resigned in a body on account of differences with the superintendent.

ONTARIO BOARD OF HEALTH.

The regular quarterly meeting of the Provincial Board of Health was held in Toronto, last week. Dr. Bryce reported that there had been in the months of June, July and August, 644 deaths, as compared with 507 for the corresponding three months in 1899, an increase of 27 per cent. A remarkable fact in this death-rate was that 264 deaths occurred in July last, or 60 per cent. more than in 1899. Dr. Bryce advises that the cities of the province increase the staff work of their health departments. Medical inspectors for schools, especially in Toronto, was also advised.

APPOINTMENT.

Dr. J. T. Halsey, of Columbia College, New York, will take charge of the Morrice Pharmacologic Laboratory at the McGill University, Montreal. This laboratory has not only been equipped by Mr. Morrice but will be supported by him for five years with annual donations, to enable the University to carry on the work of original research in this department. Dr. Halsey, after graduation, spent a year at St. Luke's Hospital. He then went to Germany, where he has spent the past five years in chemical, physiologic and pharmacologic research work in the laboratories of Frieburg, Strassburg and Marburg.

THE BIOLOGICAL STATION, ST. ANDREWS, N. B.

During the past summer, some splendid work has been accomplished in connection with the Government Marine Biologic Station at St. Andrews. During the season, the station was visited by most of the eminent scientists in Canada, who pursued special lines of research work. Amongst those doing work there were Dr. Joseph Stafford, of Toronto University; Professor Prince, of Ottawa; Dr. McCallum, of Toronto University, and Dr. A. V. Scott, of Trinity; Prof. McBride, Dr. Jackson and Mr. Simpson, of McGill; Prof. Knight and Dr. Fowler, of Queen's, Kingston, and Dr. Mackay, of Halifax. This is the second season of the station's existence, and the building has been so constructed as to lend itself easily to removal. It is likely to be removed to Prince Edward Island, next season.

FOREIGN.

Maragliano and Golgi have been elected senators, and Sanarelli deputy, to the new Italian parliament.

Koch has reached home from fifteen months of study of malaria in New Guinea, Java and adjacent islands. He is of the opinion that mosquitoes are the principal propagators of malaria in the districts he has visited.

The *Lancet* announces the election to parliament of the following medical candidates: Sir B. W. Foster, Sir M. Foster, M. A. McDonnell and F. Rutherford, in England; John Dillon, R. Ambrose, and C. K. D. Tanner, in Ireland; Sir J. Batty Tuke and R. Farquharson, in Scotland. Sir R. B. Finlay, the attorney-general, was [illegible] ctitioner.

Sir Henry W [illegible] physi
Prince of Wales, and [illegible] medi
ities of Great Brita [illegible]
He took the M.D. d [illegible]

professor of medicine in 1858, and accompanied the prince on his visit to America in 1860.

Mr. Frederick Treves, of London, one of the consulting surgeons in the South African war, has written an account of his experiences there, which will shortly appear under the title of "The Tale of a Field Hospital."

Dr. Samson Gemmel has been appointed professor of clinical medicine in the University of Glasgow, in place of Professor McCall Anderson. The latter takes the chair of practice of medicine.

The project of holding an International Congress of Gynecology and Obstetrics in London in 1902 has been abandoned. A large amount of preliminary work had been done, but certain misunderstandings developed, and as a result it was thought best to drop the matter for the present.

Russia is supplementing her stupendous anti-alcohol campaign mentioned in The Journal of September 1, p. 563, by enacting stringent laws against drunkenness. Every person found intoxicated on the streets or in public places is to be placed in jail for three days to two weeks, and on repetition imprisoned for three months. The correspondent of the *Lancet* comments that if this law is enforced, one-tenth of the inhabitants will be housed in jails.

The *Ilustracion* of Madrid states that the officials have declared that the vaccin they have been using for the last two or three thousand vaccinations is defective. It did not take in any case. Persons believing themselves safe have mingled more or less with smallpox patients, and there is much consternation over the carelessness in standardizing the vaccin, which the editor denounces as criminal.

The French courts have always upheld the principle of professional secrecy to the extreme letter of the law and consequently much surprise is expressed at a recent decision of the Toulouse court in a case involving the disposition of property. The medical attendant of the deceased was summoned as a witness and the court accepted his testimony for two reasons, first, because he had derived the information as the intimate friend of the family, and not necessarily as the physician of the deceased, and secondly, because the matter in question was widely known throughout the community.

From the recently published official report of the epidemic of the plague last year in Japan, it appears that the sanitary regulations are more advanced and stringent than in the most progressive of the western nations. The notification of cholera, dysentery, typhoid and typhus fever, variola, scarlet fever, diphtheria and plague is obligatory on the physician and also on the head of each private household and public establishment, factory, theater, school, hotel, temple, etc. The owner of the house is responsible for the execution of the measures of disinfection and cleaning ordered by the physician or the sanitary officials. Patients and even well persons can be placed in isolation hospitals at the discretion of the sanitary officials. The corpse of a person dying from one of these diseases must be cremated. As Vallin recently observed, at the Academie de Médecine: "They have jumped with both feet into the midst of European civilization and adopted the latest perfected ideals of hygiene and sanitation, untrammeled by the traditions of personal liberty, etc., with which other countries have to contend." There were 69 cases of the plague in all, with 63 deaths, including 6 among physicians or members of physicians' families. A bounty of two cents was paid for rats, and in three months 35,000 had been destroyed in Kobe and Osaka, the infected cities. Plague bacilli were found on a number of rats taken in portions of the town remote from the foci of infection.

The authorities in Germany are partial to the sick-benefit societies and are practically ignoring the rights of the medical profession in the matter. The physicians of Ludwigshafen have founded a "Society for the Protection of Physicians' Interests," based on the principle of self-help by close organization. The weekly dues of sixteen cents are accumulating a fund to reimburse physicians who incur pecuniary loss in the struggle. Dr. Hartmann, of Leipsic, has also organized a similar association for protection of the economic interests of physicians and has issued an urgent appeal to arm for the fray." "The strike of the medical men at Remscheid and Elberfeld was merely a skirmish at the outposts; the battle is liable to be raging all along the line before long." Another important weapon for the struggle is the sympathetic co-operation of the professional and lay press, which must be secured, with an energetic stand on all questions involving the social and material interests of physicians. The *Berliner Zeitung* recently published an article entitled "The Medical Proletariat." It stated that certain sick-benefit societies paid the physicians from 25 to 60 pfennings per visit, but the Bon system only pays 60 pfennings in all, although the policy-holder is insured for seven days and the physician may have to call seven times. The three months Bon system insures for three months and pays only 1.5 to 2 marks, although the physician may have to make ninety calls.

Correspondence.

Alleged Insanity in the Army.

Washington, D. C., Oct. 22, 1900.

To the Editor:—Sensational paragraphs have appeared in the daily papers concerning the prevalence of insanity among our troops in the Philippines and these paragraphs have found their way into our medical journals and have been commented on by editorial and other writers. To clear up this matter I am authorized to state to you what Surgeon-General Sternberg has said officially on this subject. A summary of his report has been given to the press, but the summary touches lightly on the question, giving merely the absolute number of cases reported. In his full report he shows that the admission rate for the army in 1898 was 1.8 per 1000 men and in 1899, 1.78. The latter rate is higher than the mean annual rate of the decade 1888-97, which was 1.7, but it was exceeded by the rate of one of the years of the decade, the year 1892, when the rate was 1.79. He continues:

> The increase in the rate of admission in 1899 over the mean rate of the decade was due to a general rise in the rates, largest in Porto Rico, 3.76 per 1000, smallest in the United States, 1.37 per 1000.
>
> This increase was to have been expected on account of the rapidity with which recruiting was effected during 1898 and 1899. It is well understood by army medical officers that among recruits there are always more mentally unsound men than among a similar number of civilians of the same age and physical development. The most careful physical examination often fails to detect a man whose brain works irregularly, but who is sane enough to go to the recruiting office. Under the stimulus and excitement of the organization of troops many such men drift to the rendezvous and must be eliminated after muster into service. Men excitable but not actually unbalanced lose their equilibrium under conditions of stress in the field and the first two years of military life are apt to develop many such cases. Hence it was to be expected that the active recruiting of the past two years would bring into the ranks men who would increase the insanity admission rate of the army. That this increase would be found chiefly among those sent to foreign service was also to be expected. No doubt many young men separated from home and friends became the subjects of intense mental depression and their cases were properly recorded on the monthly reports of sick and wounded as cases of insanity; and as the only method affording a prospect of recovery was a return to their homes they were judiciously shipped by transport to the United States. Many such cases recovered during the trans-Pacific voyage or during their detention for observation at the General Hospital, Presidio of San Francisco, Cal., and never reached the Government Hospital for the Insane at Washington, D. C. That this is no mere supposition may be inferred from the following statement concerning the insanity cases of the army as a whole and of the Philippine army:
>
> In the army, regulars and volunteers, during the calendar years 1898 and 1899, there were reported on the monthly reports of sick and wounded 347 cases of insanity, and 202 of these cases or 58.2 per cent., were committed to the Government Hospital for the Insane. One hundred and thirty-five cases, or 66.7 per cent. of the commitments, recovered in an average period of 3.9 months, 13 were improved, 6 died, and 48 remained unimproved. Ninety-six of the 347 cases were

reported on the monthly reports of troops serving in the Pacific islands, and 32 of these, or 33.3 per cent., were sent to the Government Hospital for the Insane. Seventeen cases, or 53.1 per cent., of those committed recovered in an average period of 3.6 months, 2 were improved, 2 died and 11 remained not improved.

It is not deemed necessary to do more than present these official figures to silence the sensational newspaper paragraphs which have been published during the past year relative to the unusual number of cases of insanity which have been returned to the United States from our troops operating in the Philippine Islands. Respectfully, Charles Smart,

Lieut.Col., Deputy Surg.Gen., U. S. Army.

Traumatic Neuroses.

Waverly, N. Y., Oct. 13, 1900.

To the Editor:—I note with surprise the discussion on Professor Bevan's paper in issue of September 22. Is it possible the majority of those taking part in the discussion represent the highest attainment of the neurologists of the present era? If so, there is small wonder that corporations do not generally employ them. I have too much respect for the eminent men, universally known and esteemed throughout the world, who have espoused that field to believe any such thing. Professor Bevan's experience is that of most experienced surgeons, be they railway surgeons or others. While I can not concur in all he says, in the main my experience for thirty years corroborrates his views. But I wish briefly to refer to such authorities as Brourdel, Paget, Charcot and many others of equally worldwide fame, who state the proportion of simulated cases of traumatic neuroses as high as 80 per cent. One such authority claims that they often nurse themselves into a condition of pathologic entity resulting in serious lesions, sometimes resulting even in death. While I do not believe so large a percentage are consciously fraudulent, I do believe a very large percentage, a large majority even, are unconsciously so. Through psychic influences such conditions are engendered and engrafted on the nervous system, and much tact on the part of the surgeon or neurologist is necessary to overcome them. We should consider a very large percentage pure simulation, but not declare them as such to the patient. We should be careful not to overlook the genuine cases and to call to our aid the experienced neurologist if necessary.

R. Sayre Harnden.

Medical Practice in Australia.

Sydney, New South Wales, Sept. 14, 1900.

To the Editor:—You have asked me to give you an occasional short letter. In the Australian colonies lodge practice has become a subject of much interest to the medical profession. Nearly one-fourth of the total population participates in cheap medical attendance through the means of these medical "friendly societies." There are 2650 medical men in the colonies, and of these 170 hold government positions, which prevents them from having private practice. One-third of the remainder have lodges, nearly 1200 souls to every lodge physician.

The medical profession is attempting to change existing conditions, but finds some difficulty in doing so. The lodge practice offers a ready means to the young practitioner to start in life; £150 to £200 per annum gives him some assistance while gaining a private practice. A change in the present system would be an advantage to the profession and public. In 1901 all the colonies come under a federation, and very probably after such a change more harmonious regulations will be established in regard to medical practice.

Years ago men holding American diplomas established some
rather poor records in Australia. The h
rather conservative, so that all Ame
medical man here is somewhat at
has an English degree.

Average Doses in the Next Pharmacopeia.—A Protest.

Saguache, Colo., Oct. 20, 1900.

To the Editor:—At the last convention for the revision of the U. S. pharmacopeia an instruction was given to the revision committee to insert the average dose of each article. This was stated by one of the leaders to be merely a concession to the demand by physicians that the forthcoming revision should result in a more practical manual for their use. In this spirit it was adopted without debate or alteration.

Conversation since that time with many of the delegates to that convention, as well as with professional gentlemen from all sections of the country, convinces us that average doses are not wanted in this work by either physicians or pharmacists, as in many instances they must be a wholly indeterminate quantity, owing to the wide range of conditions that are to be met, and under no circumstances could they be more than a treacherous guide to inexperience.

What is wanted both by physicians and pharmacists and what they have for more than twenty years been demanding is the insertion in this work of maximum safe doses, the intentional exceeding of which by the prescriber shall be indicated by an exclamation mark or otherwise.

This step would bring the work into accord with other standards, assure the prescriber of the usual limit of safe dosage in producing the specific effect of the drug and guide the pharmacist in discriminating between an error and an intentionally large dose. Few situations are more responsible and perplexing to a prescription clerk than to receive a prescription containing unusual doses, yet having no authoritative standard which will justify him in declining to prepare it until he can consult the prescriber. This vital point will be in no way improved by the proposed insertion of the average dose.

The "average" dose of any drug is almost wholly a matter of individual experience and method of treatment. Scarcely two of our American authorities will agree within wide limits on the best dose of a given remedy, even for the same complaint. How absurd, then, to specify an average dose for all complaints and all conditions of environment. The average dose of quinin in the Mississippi Valley would mean certain delirium in our mountain climates. Therefore the one demand for the protection of physician, pharmacist and patient is that this authoritative standard shall simply indicate the maximum safe dose of its preparations which may be exceeded by the prescriber, if necessary, by his indicating that he recognizes its unusual size, and from which he may descend toward infinity just as far as his judgment may guide, that is immaterial; the "maximum" dose is the important and serious one which every one who in any way handles drugs must know. The "average" dose is of service to few. Can not this error, as we consider it, be rectified before the labor of revision goes too far? There will probably be two years yet before its publication. J. Tracy Melvin, Ph.G., M.D.,

Member Convention for Revising U. S. Pharmacopeia, 1900.

Deaths and Obituaries.

Ross Richardson Bunting, M.D., Jefferson Medical College, Philadelphia, 1856, died at his home in Roxborough, Philadelphia, Oct. 9, aged 66. He was the only child of Dr. Thomas Chalkley Bunting. After receiving his degree he studied five years in France and was one of the first Americans to receive the diploma of the Ecole de Médicine of the University of Paris. On his return to America he took charge of the practice of his uncle, Dr. Ross Richardson. He was a member of the principal medical societies and a frequent
medical lit.

utt, of Pennsylvania,
at th, Va., Oct. 9,
ing physicians
Confederate
smouth.
rs. The

Medical Society of the City of Portsmouth, at a called meeting, Oct. 11, passed resolutions expressing sorrow at his death and respect to his memory.

Ellis Horton, M.D., Medical College of Indiana, 1875, one of the best known physicians in Morgan County, died Oct. 6, from heart disease, a few hours after the death of his wife, at Monrovia, Ind., aged 58. He was the author of the "Hoosier Practitioner," a book which attracted considerable attention when it appeared a few years ago.

Benjamin F. Templeton, M.D., Starling Medical College, Columbus, O., 1887, of Zanesville, died at the City Hospital, Findlay, from appendicitis, Oct. 2, aged 35. The Muskingum County Medical Society at its meeting, Oct. 5, passed resolutions of respect to his memory and of sympathy to his bereaved family.

Andrew C. Bergen, M.D., an old resident of Sioux City, Ia., a graduate of Long Island College Hospital in 1870, lieutenant-colonel and assistant surgeon-general Iowa National Guard, and major-surgeon 52d Iowa Infantry, U. S. V., in the Spanish-American War, died from apoplexy, October 3.

Wadsworth A. Ward, M.D., Conneaut, Ohio, died September 30, after a long illness. He was graduated from the medical department of Western Reserve University, Cleveland, in 1861, resided for nearly forty years in Conneaut, and was surgeon to the Chicago, New York & St. Louis Railway.

Abner V. Doak, M.D., who studied medicine in the University of Virginia, served during the Civil War as surgeon in the Confederate service, was graduated from Bellevue Hospital Medical College and then engaged in general practice in Taylor, Tex., died September 15, aged 62.

William W. Brown, M.D., died a few hours after a cerebral hemorrhage, brought about, it is claimed, by an exciting automobile ride, at his home in Brooklyn, N. Y., October 5, aged 48. He was a graduate of Bellevue Hospital Medical College in 1884.

Benjamin F. Temple, M.D., died at Zanesville, Ohio, October 2, two days after an operation for appendicitis had been performed. He was graduated from Starling Medical College, Columbus, in 1887, and was 35 years of age.

William C. Towle, M.D., Medical School of Maine, 1855, died recently at his home in Fryeburg, Me., aged 70 years. During the Civil War he served as surgeon of the 12th and 23d Maine and the 8th Indiana regiments.

Charles Mitchell, M.D., University of Louisville, 1871, died recently at Nashville, Tenn. The Nashville Academy of Medicine met Oct. 4, to express the esteem felt for Dr. Mitchell and the regret at his death, and appointed a committee to draft suitable resolutions.

Titus Duncan, M.D., University of Michigan, 1862, one of the oldest and best known practitioners in Michigan, who served throughout the war in the medical department of the army, died at his home in Saginaw, Oct. 4, after a lingering illness, aged 66.

John Paul Jones, M.D., Bellvue Hospital Medical College, 1886, formerly a medical officer in the navy, and later a resident of Pine Bush, N. Y., died suddenly at Comfort, Texas, Sept. 26, age 38.

John T. Miller, M.D., who, although a graduate in medicine, had not practiced for many years, died at his home and birthplace, Edgewood, near Louisville, Ky., Oct. 12, from cancer of the stomach, aged 69.

Curtis Clark Strong, M.D., Bellevue Hospital Medical College, New York, 1872, who had practiced medicine for twenty-eight years in Portland, Ore., died in that city Oct. 11, after a lingering illness, aged 52.

George W. Woodliff, M.D., Atlanta, (Ga.) Medical College, 1888, a resident of Oscarville, Forsyth County, died from rheumatism at the Grady Hospital, Atlanta, Oct. 3, aged 39.

William R. Larkin, M.D., Bellevue Medical College, 1880, surgeon of the New York Fire Department for many years, died at his home in New York, Oct. 15, aged 42.

James H. Lafferty, M.D., College of Physicians and Surgeons, Baltimore, 1881, and for many years a practitioner at New Florence, Pa., died Oct. 14, after an illness of about two weeks, aged 46.

Joseph L. Cutler, M.D., New York University, 1850, and since that time a resident of Bolivar, N. Y., and a leading surgeon of Allegheny County, died at his home, Oct. 14, from uremic poisoning, aged 71.

John W. Elston, M.D., Bellevue Hospital Medical College, New York, 1871, one of the pioneer-physicians of Kansas City, Mo., died in Burila, Colo., Oct. 12, from Bright's disease, aged 56.

Franklin Smith, M.D., University of New York, 1865, died on Oct. 9, at his home, in New York City, where he had practiced for more than twenty-five years, age 76.

Louis Roch Perrault, M.D., Laval University, Quebec, 1887, who had practiced for a long time at Franklin Falls, N. H., died from cancer, Oct. 16, aged 38.

N. J. Paschall, M.D., Jefferson Medical College, 1869, a prominent physician of Fulton, Ky., died at his home, Oct. 12, two days after a stroke of paralysis.

Henry B. Gwynn, M.D., Baltimore University, 1887, who had been engaged for many years in teaching, and was principal of Grammar School No. 1 in Baltimore, died at Gordonsville, Va., Oct. 11, from paralysis, aged 45.

T. H. Hairston, M.D., University of Louisville, 1892, died at Marlin, Texas, Oct. 7, from hemorrhage of the bowels, after an illness of two weeks, aged 33.

David Brock, M.D., Tennessee Medical College, Knoxville, 1899, died at his home, Unitia, Tenn., Oct. 7, from consumption, aged 27.

William M. Caterson, M.D., Jefferson Medical College, Philadelphia, 1875, died at his home in Philadelphia, Oct. 7, aged 70.

George Nelson Jones, M.D., McGill University, Montreal, 1874, died at his home in Burlington, Iowa, Oct. 17, aged 48.

Benjamin A. Fichtner, M.D., Confluence, Pa., died at Mount Pleasant, Oct. 7, from hemorrhage of the bowels, aged 65.

James M. Suggett, M.D., Transylvania University, Lexington, Ky., 1847, died at his home in Flora, Ill., Oct. 9, aged 77.

John C. Bechtel, M.D., University of Pennsylvania, Philadelphia, 1876, died Oct. 11, at Rehrersburg, Pa., aged 49.

Milton D. Brown, M.D., Harvard University Medical School, Boston, 1894, of Baltimore, died recently at the residence of his parents, Charles City, Va.

John Gordon Frazer, M.D., New York University, 1865, formerly of New York City, died Oct. 4.

Benjamin Hussey West, M.D., Harvard University, 1838, a resident of Boston, died Oct. 11, aged 86.

John Mills, M.D., Pana, Ill., died Oct. 16, aged 81.

Miscellany.

Explanation.—Owing to an oversight part of the discussion of Dr. Peter A. Callan's paper on "Operations for Secondary Cataracts," in issue of October 13, was omitted. It will appear next week.

Extirpation of Gasserian Ganglion.—F. Krause now has a record of twenty-four cases of rebellious trigeminal neuralgia treated by extirpation of the Gasserian ganglion. Two of the patients have died since, the deaths not being directly imputable to the operation. All the rest are permanently cured.

Experimental Extirpation of the Liver.—Salaskin states that some dogs survived for three to five hours after extirpation of the liver. The urea in the urine was diminished during the interval before death, but not to such an extent in proportion, as the decrease in uric acid in geese after extirpation of the liver.

Sterilization of Sponges.—Carrière reports in the *Arch. Prov. de Chir.*, 1900, ix, that sponges can be rapidly and effectively sterilized without injuring their structure, in a 10 per cent. solution of hydrogen peroxid, in which they are left to soak for twenty-four hours. The absorbent properties of the sponges are not diminished even after six or seven months in the solution. The abstract in the *Cbl. f. Chir.* mentions that his tests were restricted exclusively to the bacillus subtilis.

Useless Efforts.—Certain of our foreign exchanges are commenting editorially in a pessimistic vein, on the futility of all efforts to educate the public in the matter of hygiene. "The most impassioned apostles of hygiene and sanitary progress seem to be powerless to convince even their own wives and daughters of the dangers of trailing their skirts through the filth of the streets, collecting animal ordure and urine and pathogenic microbes, and then dragging them into private houses."

Ophthalmic Hints.—The *Berliner Klin. Woch.* for July 9 mentions two practitioners who have found mercury extremely effective in ocular affections: Heddaus uses calomel internally or inunctions of gray ointment in blepharitis, and Guthmann, calomel, combined with local treatment in scrofulous and ocular affections. Jaqueau advises sewing the eyelid down after operating for cataract, in case of senile, rebellious or imbecile patients. Wolfberg recommends a hollow bandage after operations on the eye, made of lint mixed with glycerin-gelatin or formalinized bookbinders' glue, moulded over the orbit to form a tight, hollow cap, closely adhering but nonirritating.

The Blister as a Means of Determining Death.—The *Journal de Médecine*, of Paris, of August 19, states that an absolutely reliable means of determining whether death is apparent or real, is to hold a candle to the skin for a few moments until a blister forms, which soon occurs. If there is still life in the body the blister will be filled with serous fluid, in obedience to the inevitable physiologic laws, but if death has actually occurred, the tissues obey only the physical laws, and these compel the fluid in a heated tissue to pass into the form of vapor. Therefore, if the blister contains merely steam, the body is an inert cadaver, but if the contents are fluid, life is not extinct.

Should We Treat Fever?—In the discussion of this question at the International Medical Congress, Stockvis declared that "nursing, not treatment," was what febrile patients require; hygienic, analeptic, dietetic measures, hypurgia. Robin observed that in simple hyperthermia the general oxidations are increased, while in grave hyperthermia the oxidations are diminished and merely the elementary phenomena of disassimilation are augmented. The chemical processes of the organism, the diuresis and the nervous system should be stimulated in the latter. Reduction of the temperature alone is useless, as it is merely one manifestation of the febrile state. Huchard pointed out the varieties of fever in tuberculosis for example, each originating from a different process, germination, inflammation or absorption. Antithermia, he concluded, is easily induced, but of little practical use; antipyresis is more difficult to attain, but its triple aim of promoting chemical interchanges, diuresis and stimulating the nervous system, is sometimes reached by cold baths and weak doses of quinin—large doses produce the opposite effect.

A Peculiar Case of Cyanosis.—Dr. William Osler reports a remarkable case of cyanosis in a young white man now at the Johns Hopkins Hospital. He is a Pole, and it was difficult to elicit his history. He entered October 3. His illness began September 29, with chill, fever, pain in the chest, stomach and head and diarrhea. He had also had cough and expectoration and had been confined to bed. On admission he complained of pain in the abdomen, had considerable dyspnea, dry tongue and deep cyanosis. The respirations were 30 per minute, but the dyspnea was not urgent. There was slight emphysema and asthma. The leucocytes numbered 18,000. There was practically no fever, the temperature being, as a rule subnormal. He had remained practically in the same condition, the cyanosis being as noticeable in the recumbent as the erect posture. On October 7 petechiæ appeared about the face and extended over the entire body except the legs. The appearance was very like malignant hemorrhagic smallpox. The eosinophiles were 11 per cent. October 11, he complained of extreme tenderness over the muscles, and some muscular tissue was extirpated for examination. Much fatty degeneration was found. The eosinophiles were 25 per cent. October 14 the cyanosis began to diminish. Blood cultures were negative. Albumin was doubtful; there were no casts. The muscular tenderness had disappeared. Pulse good. There was a little puffiness of the face and eyelids. The petechiæ were still extensive. Dr. Osler regarded the case as entirely anomalous.

MARINE-HOSPITAL NOTES.

Asst.-Surgeon J. W. Kerr, who has been detailed for duty in the office of the United States Consul-General at Hong Kong, China, sailed from Honolulu for Hong-Kong on the steamship *Coptic* on Sept. 22.

QUARANTINE SERVICE IN PHILIPPINE ISLANDS.

An executive order has been issued which details a commissioned officer of the Marine-Hospital Service on the staff of the military governor of the Philippine Islands as chief of the quarantine service of the islands. P. Asst.-Surgeon J. C. Perry has been detailed as such officer.

YELLOW FEVER IN HABANA.

Reports from Surgeon Glennan at Havana show that for seventeen days ending October 17, there were 175 new cases and thirty-nine deaths.

Asst.-Surgeon R. L. Wilson has been ordered from San Francisco to Honolulu to report to Surgeon Carmichael for duty at the marine-hospital station recently established at Honolulu for the treatment of seamen of the American merchant marine. Asst.-Surgeons Dunlop Moors and Carroll Fox, and Hospital Steward Myron R. Mason have been ordered to return from Dutch Harbor, Alaska, at the close of navigation. Assistant Surgeons B. H. Earle and B. J. Lloyd, who have been on duty at the national quarantine station at Nome, Alaska, are expected to return on the last revenue cutter leaving Nome at the close of the season.

The acting asst.-surgeons at the fruit ports of Central and South America have been ordered to return to the United States, November 1. This inspection service will be re-established on the same lines the coming season. The acting asst.-surgeons who were appointed in July last at Handsboro, Biloxi, Pascagoula, Scranton, Bay St. Louis, Pass Christian, McHenry, Ocean Springs and Gulf Port, Mississippi, to act as sanitary observers with a view especially to the early detection and report of first cases of yellow fever on the Gulf Coast, have also been discontinued. In addition to the places named above, the service has had its regular officers in all large ports on the South Atlantic and Gulf, who were given special instructions to maintain vigilance at their respective ports.

SANATORIUM FOR CONSUMPTIVE SAILORS.

The Marine-Hospital Sanitarium at Fort Stanton, New Mexico, is now pretty well equipped, and there have been admitted since November, 1899, up to the present time, 78 patients suffering with tuberculosis. Of these 11 have been discharged recovered, 13 improved in health with prospect of recovery, and 8 have died, showing a very fair percentage of recoveries. Of the 8 who died, 7 were cases too far advanced at the time of their arrival to be benefited by the change of climate. It would seem from the above that the establishment of this sanitarium, which was sanctioned by the last Congress, was a wise measure, and it is in line with the efforts of State and municipal authorities to make provision for this class of patients.

PLAGUE SITUATION IN GLASGOW.

Cable reports from P. A.-Surgeon Thomas, at Glasgow, show that for the week ended September 29 there were four deaths from plague in the city, but no new cases; week ended October 6, one death but no new cases; and during the week ended October 13 there were no deaths and no new cases. The authorities, therefore, have probably succeeded in suppressing the epidemic. During the outbreak there have been eight deaths all told.

A CASE OF PLAGUE AT SAN FRANCISCO.

Another case of plague has been reported by the local board of health at San Francisco as occurring October 5, the diagnosis having been confirmed by bacteriological examination, October 11. The case was taken from the same house from which a fatal case was taken July 5 to the City Hospital. This is the first case reported since August 18. It is presumed that the case was a Chinaman, as were the other cases.

YELLOW FEVER IN HABANA.

Reports from Surgeon Glennan, at Habana, show that for the week ended October 5 there were 55 cases of yellow fever officially reported in that city, with 16 deaths, and for the week ended October 12 there were officially reported 76 cases, with 14 deaths.

DETENTION OF NON-IMMUNE PASSENGERS FROM HABANA.

The value of the quarantine regulations requiring detention at northern ports of non-immune passengers from Habana a length of time to complete five days from departure was illustrated recently at the New York quarantine. A saloon passenger who had been given a red ticket at Habana by Surgeon Glennan, thus indicating that he was not immune, was detained at Hoffman Island. The voyage from Habana generally requires three and one-half days, so the passengers of this class are subject to one and one-half or two days detention. The same night, he developed a marked case of yellow fever and was transferred to Swinburne Island, where, according to Dr. Doty, he is doing well.

AN IMPROVED FORMALDEHYDE GENERATOR.

Under date of August 14, 1900, the acting director of the laboratory made a report to the surgeon-general on an improved formaldehyde lamp, of which a thorough test, lasting about a month, had been made. This lamp, known as the Kuhn Generator, is an apparatus designed to produce formaldehyde gas by the de-hydrogenization of wood or methyl alcohol. This is accomplished by passing the vapor of alcohol through discs or plates which contain incandescent, metallic platinum in a state of fine division. It is an improvement on the lamp that was designed and reported on by Surgeon Kinyoun. So satisfactory were the results of the tests that a dozen of the lamps have been purchased and are now in actual operation at the quarantine stations, where a thorough test of their durability, as well as practical utility, will be made. The advantages of an efficient lamp of this kind are so many that an enumeration of them in a short article is impossible. The full report, giving the details of the experiments, will be published shortly.

Societies.

Coming Meetings.

Southern Surgical and Gynecological Association, Atlanta, Ga., Nov. 13-15.

The Tri-State Medical Association of Mississippi, Arkansas and Tennessee, Memphis, Nov. 13-15.

Oklahoma Territory Medical Society, Oklahoma City, Nov. 15.

Indian Territory Medical Association, Muscogee, Dec. 4-5.

Pan-American Medical Congress, Havana, Cuba, Dec. 26-28.

Western Surgical and Gynecological Association, Minneapolis, Minn., Dec. 27-28.

The Amesbury (Mass.) Medical Association, at its annual meeting, October 12, elected Dr. John A. Fitz-Hugh secretary and Dr. John A. Douglass, treasurer.

The Delaware County (Ind.) Medical Society met at Muncie, October 10. Dr. George W. H. Kemper presented a paper entitled "A Half-Hour with Hippocrates."

The Brookline (Mass.) Medical Club has elected the following officers: Dr. J. Henry Woods, president; Dr. Henry M. Cutts, vice-president, and Dr. George H. Francis, secretary and treasurer.

The Iowa and Illinois District Medical Society held its quarterly meeting at Rock Island, Ill., October 11, and listened to a paper by Dr. St. Elmo M. Sala, Rock Island, on "The Treatment of Typhoid Fever."

The Osage County (Kas.) Medical Society organized at Osage City, October 9, and elected the following officers: Dr. Albert L. Stubbs, Burlingame, president; Dr. Edwin B. Packer, secretary, and Dr. William B. Artz, treasurer.

A "Physicians' Club" has been formed at Greenfield, Mass. At the initial meeting, October 10, Dr. Halbert E. Stetson, Greenfield, was elected president and Dr. George A. Cooke, Montague, secretary and treasurer.

The Essex North District (Mass.) Medical Society entertained the Essex South District Medical Society at its meeting in Newburyport, October 10. Dr. William B. Coley, New York, delivered an address on "The Results of Modern Methods in the Treatment of Cancer."

The Detroit Academy of Medicine, at its annual meeting, October 9, elected Dr. Arthur D. Holmes, president; Dr. Heneage Gibbes, vice-president, and Dr. Harrison D. Jenks, secretary-treasurer. A special committee was appointed to investigate the Physicians' Business League.

The Clark County (Ky.) Medical Society met at Winchester, October 13. Dr. J. N. McCormack, Bowling Green, secretary of the State Board of Health, addressed the society on state sanitary matters with especial reference to county boards of health.

The North Berkshire District (Mass.) Medical Society met at North Adams, September 25, and elected the following officers: Dr. William Galvin, Blackinton, president; Dr. Nicholas Crofts, North Adams, vice-president; and Dr. Lyman A. Jones, North Adams, secretary and treasurer.

The Ophthalmological and Otological Society of Washington, Dr. S. O. Richey, president, held its first fall meeting, October 9, at the residence of Dr. W. K. Butler, who read the paper of the evening, entitled, "The Necessity for Wearing Glasses."

The Guthrie District (Okla.) Medical Society organized on September 29 and held its first regular session, October 10, with the following officers: Dr. John R. Hamil, president; Dr. Abraham L. Blesh, vice-president, and Dr. Eugene O. Barker, secretary.

The Northeastern Iowa Medical Society held its semiannual meeting at Waukon, October 12, at which papers were presented by Dr. Daniel H. Bowen, Waukon, on "Typhoid Fever"; Dr. J. Cliff Crawford, Waukon, on "Catarrhal Pneumonia," and Dr. Philo M. Jewell, Decorah, on "Surgical Appendicitis."

The Orange Mountain (N. J.) Medical Society held its two hundredth meeting, Oct. 12, at Newark. The president, Dr. James S. Brown, Montclair, paid a tribute to the memory of the late Dr. William Pierson. Dr. Thomas W. Harvey, Orange, then gave a short résumé of the history of the society since its organization in 1883.

The Lawrence County (Pa.) Medical Society held its annual election of officers at New Castle, Oct. 11, with the following result: Dr. John Foster, president; Drs. Wallace and Charles A. Reed, vice-presidents; Dr. Edwin C. McComb, secretary, and Dr. William G. Wilson, treasurer, all of New Castle.

The Jackson County (Mo.) Medical Society held its annual meeting at its rooms in Kansas City, Oct. 11, and elected the following officers: Dr. Amos A. Freyman, president; Dr. Winn F. Morrow, vice-president, Dr. Franklin E. Murphy, secretary; Dr. Louis W. Luscher, treasurer; Dr. Charles B. Hardin, censor, and Dr. Edward H. Thrallkill, librarian.

The San Joaquin Valley (Cal.) Medical Association held its annual meeting at Visalia, October 9, and elected the following officers: Dr. J. Lawrence Maupin, Fresno, president; Drs. John B. Rosson, Tulare, Henry Hildreth, Delano, and Thomas O. McSwain, Visalia, vice-presidents; Dr. Joseph D. Davidson, Fresno, secretary, and Dr. Thomas M. Hayden, Fresno, treasurer.

The Medical Association of the St. Francis District, P. Q., at its quarterly meeting at Sherbrooke, elected Dr. T. L. Brown, Richmond, president, Dr. Stevenson, Coaticook, vice-president, and Dr. Thomas, Lennoxville, secretary. The transmission of typhoid fever and the question of medical fees were discussed.

The Chicago Gynecological Society held its annual meeting, Oct. 19, 1900, and elected the following officers: Dr. Reuben Peterson, president; Drs. Lester E. Frankenthal and Henry Bangs, vice-presidents; Dr. William H. Rumpf, secretary; Dr. Addison H. Foster, treasurer; Dr. Charles S. Bacon, editor; Dr. Emil Ries, pathologist.

The Idaho State Medical Society, at its meeting at Boisé, October 4 and 5, elected the following officers: Dr. Joseph R. Numbers, Weiser, president; Dr. Hubert A. Castle, Pocatello, vice-president, and Drs. John W. Given, Blackfoot, Robert L. Nourse, Hailey; Jesse L. Conant, Genesee; Charles W. Shaff, Lewiston, and Lucian P. McCalla, Boisé, board of censors.

The Wayne County (Mich.) Medical Society, at its annual meeting, October 4, elected Dr. John J. Mulhern, president; Dr. Samus Bell, vice-president; Dr. George G. Gordon, secretary, and Dr. C. Henri Leonard, treasurer. Dr. Edgar B. Smith offered at paper on "Preparation for Surgical Operations"; and Dr. Edward T. Milligan addressed the society on October 18, on "Adenoid Vegetations."

The Cumberland District (N. J.) Medical Society convened at Millville, October 9, when papers were presented by Dr. Dowling Benjamin, Camden, on "Some Mooted Points in Pelvic and Abdominal Surgery," and by Dr. Charles W. Wilson, Vineland, on "Treatment of Appendicitis from the General Practitioner's Standpoint." Dr. S. Thomas Day, Port Norris, was elected reporter for the ensuing year.

The Hartford (Conn.) City Medical Society at its October 1 meeting was presented by Dr. W. Gordon Russell with a stately carved oaken chair for the use of its presiding officer and also with some beautiful anatomical drawings, the donor of which wished to remain unknown. Drs. Arthur J. Wolff and Charles E. Taft reported cases and presented specimens, and Dr. George R. Shepherd read a paper on "Non-Surgical Methods for Treating Cancer."

The Brashear Medical Society held its quarterly meeting at Bloomfield, Ky., October 16. Dr. Aloysius G. Blincoe, Bardstown, read a biographical sketch of Dr. Walter Brashear, and a paper on "Some Facts, Fancies and Fallacies About Eye-Strain"; Dr. William W. Ray, Springfield, presented a paper on "Some Practical Trifles"; Dr. Benjamin E. Gore, Bardstown, one on "What Shall We Prescribe?" and Dr. J. T. Tichenor, Waterford, one on "Erysipelas."

The Middlesex Sohth District (Mass.) Medical Society met at Cambridge, October 10. Dr. Zabdiel B. Adams read a paper entitled "When Should the Medical Examiner Be Called?" Dr. Julian A. Mead, Watertown, considered "The Duties of the Medical Examiner"; Dr. Eugene G. Hoitt, Marlboro, compared the "Advantages of the Medical Examiner System Over the Coroner System," and made suggestions toward the betterment of the present law, and the Hon. John R. McLaughlin discussed "The Medical Examiner and the Physician in the Witness-Box from the View-Point of the Lawyer."

The Cheshire County (N. H.) Medical Society held its annual meeting at Keene, October 9. The guest of the evening was Dr. Charles G. Cumston, Boston, who delivered an address on "Cancer of the Liver and Gall-Bladder." Dr. Silas M. Dinsmoor, Keene, read a paper on "Some New Remedies," and the retiring president, Dr. Israel A. Loveland, Gilsum, delivered the annual address on "The Prevention of Nervous Diseases Throughout the State."

The McDonough County (Ill.) Medical Society held its annual meeting at Macomb, October 2. Papers were read by Dr. John P. Roark, Bushnell, on "Rheumatism"; Dr. Arthur D. Pollock, Macomb, on "The Treatment of Typhoid Fever and Its Complications," and Dr. Samuel C. Stremmel, Macomb, on "Dysmenorrhea." The following officers were elected: Dr. Joseph B. Holmes, Macomb, president; Drs. John B. Roark, Bushnell, and Henry Knappenberger, Macomb, vice-presidents; Dr. Robert E. Lewis, Macomb, secretary and treasurer, and Dr. Elizabeth R. Miner, Macomb, necrologist.

The Somerset County (Pa.) Medical Association held its annual meeting at Meyerdale, October 18. and elec[illegible] lowing officers: Dr. Bruce Lichty, Meyersdale, pr[illegible] Henry Garey, Berlin, v[illegible]sident [illegible]. H. Clay Meyersdale, secretary [illegible] Meyer[illegible] responding secreta[illegible] Co[illegible] treasurer.

The Fulton County (Ill.) Medical Society held its third annual meeting at Canton, October 2, and elected the following officers: Dr. W. E. Schallenberger, Canton, president; Drs. Perry H. Stoops, Ipava, and S. B. Bennett, Canton, vice-presidents; Dr. David S. Ray, Jr., Cuba, secretary, and Dr. Frank M. Harrison, Bryant, treasurer. Dr. Paul S. Scholes, Canton, read a tribute to the late Dr. Joseph V. Harris; Dr. Ellen Heise, Canton, presented a paper on "Smallpox"; Dr. Willis T. Ziegler, Canton, one on "Appendicitis," and Dr. Thomas R. Plummer, Farmington, one on "Tonsillitis."

The National Association of Colored Physicians and Surgeons held its fourth annual meeting at St. Louis, October 3 and 4. Papers were read by Dr. John W. Rowland, Pine Bluff, Ark., on "La Grippe Meningitis"; Dr. Willis E. Sterrs, Decatur, Ala., on "Typhoid Fever"; Dr. John W. Norrell, Elizabethtown, Ky., on "Carcinoma of the Pyloric End of the Stomach." The following officers were elected: Dr. Ferdinand A. Stewart, Nashville, Tenn., president; Dr. A. Wilberforce Williams, Chicago, vice-president; Dr. John W. Norrell, Elizabethtown, Ky., secretary, and Dr. Ottoway T. Fields, St. Louis, treasurer. The next meeting will be held in Hot Springs, Ark., in September, 1901

The Iowa State Association of Railway Surgeons convened at Des Moines, October 11, for its seventh annual session. President Dr. Nathan C. Morse delivered an address in which he urged that the principles of first-aid be taught in our public schools and generally. Papers were read by Dr. John N. Warren, Sioux City, on "Fractures of the Pelvis"; Dr. David S. Fairchild, Clinton, on "Sequela of Case of Nerve Injury Presented at Clinton Meeting"; Dr. Gilbert Baldwin, Ruthven, on "Talma's Operation, Report of Case"; Dr. John C. Schrader, Iowa City, on "Railway Surgeons as Sanitarians"; Dr. Van Buren Knott, Sioux City, on "The Use of Anesthesia in the Diagnosis and Treatment of Fractures"; Dr. Henry C. Eschbach, Albia, on "Ununited Fractures"; Dr. Paul E. Gardner, Hazleton, on "Injuries of the Elbow-Joint": Dr. Francis V. Shore, Des Moines, on "The Simulation of Eye Diseases"; Hon. Carroll Wright, Des Moines, on "The Relation of the Railway Surgeon to His Patient"; Dr. Gilbert G. Cottam, Rock Rapids, on "Technic and Limitations of Emergency Surgery"; Dr. Arthur L. Wright, Carroll, on "Hernia"; Dr. George C. Stockman, Mason City, on "Submeningeal Cocain Anesthesia"; Hon. W. H. Bailey, Des Moines, on "What Pecuniary Compensation Should One Receive for Disabling Injury or Loss of Life?" The following officers were elected: Dr. Gilbert G. Cottam, Rock Rapids, president; Dr. Arthur L. Wright, Carroll, vice-president; Dr. Ira K. Gardner, New Hampton, secretary, and Dr. Gilbert Baldwin, Ruthven. treasurer. Des Moines was selected as the next meeting-place of the association.

New York State Medical Association.

Seventeenth Annual Meeting, held in New York City, Oct. 15-18, 1900.

President Dr. E. D. Ferguson, Troy, in the chair.

There was a very largely-attended meeting of the Council and Fellows held in the forenoon of the first day at the New York Academy of Medicine, in accordance with the plans for re-organization of the State Association. It will be remembered that the "Fellows" are the delegates appointed to represent the whole Association on a basis of representation of one in ten. The meeting was called to order promptly by the president of the Association, Dr. E. D. Ferguson, who then delivered an address in which he set forth the more important changes which it was proposed to make in the organization of the Association.

Dr. Frederick Holme Wiggin, chairman of the Committee on Reorgan[illegible], in presenting the report of this committee— [illegible] delivered an address in which he [illegible] need for better organization, and [illegible] been awakened in various parts [illegible] with the proposed action of

An attempt was then made to consider the by-laws seriatim, but after considerable discussion it became evident that those present had not fully grasped the full meaning of the proposed plan, and accordingly the by-laws were referred to an enlarged committee.

The Association was called to order by the President promptly at 10 a. m., Tuesday, and it then formally accepted the charter procured last spring. This having been done, the Association took a recess to allow an opportunity for the Council and Fellows to meet and pass on the proposed by-laws. The enlarged committee presented to this body the result if its labor since the session of the day previous. In brief, it may be said that while they recommended the adoption of the general plan, as printed and circulated, they were in favor of certain minor changes. Among the latter, was the proposition to postpone, for the present, the institution of associated medical defense and the conferring of a death-benefit. After a very full discussion by the Council and Fellows, the report of the committee was adopted, the new by-laws stating very clearly the purpose of the Association to embark in the work of defending its members against suits for malpractice at no very distant day. This preliminary business served to clear the air of many doubts, fears and suspicions thaat had hovered over the convention at its first session, and in the succeeding days of the meeting it was a matter of common remark that the spirit of harmony and good fellowship was abroad, and that the members of the New York State Medical Association were cemented together by closer ties than ever before.

A NEW THEORY OF MUSCULAR RHEUMATISM.

Sir James Grant, Ottawa, at the opening of the regular scientific session, was presented to the Association, and he embraced the opportunity to describe his studies in muscular rheumatism, and his recently published conclusion, to the effect that muscular rheumatism is dependent on the accumulation in the muscles of an abnormal charge of electricity. The treatment, founded on this theory, has certainly proved very successful in his hands. It consists in plunging a number of fine needles into the affected muscles, and almost immediately withdrawing them. When this had been done, it would be found that the rigidity and pain in the muscles had disappeared. By connecting the needles with an electrometer one could easily satisfy himself of the existence of the electrical charge, as well as of its removal by passage through the uninsulated needles to the person of the physician.

ANALOGY BETWEEN NERVOUS AND ELECTRIC CONDUCTIBILITY, AND THEIR RELATION TO FUNCTIONAL NEUROSES.

Dr. A. D. Rockwell, New York City, read a paper with this title. He considers that there is an analogy between nerve conductibility and the variations in electric conductibility noticed in an instrument known as a "coherer." This is a glass tube filled with iron filings. It does not normally conduct electricity, but if placed in a solenoid situated in the path of a high frequency current, it at once becomes a conductor, presumably because this current has produced an expansion of the sheaths of condensed ether supposed to surround each particle of metal. The natural resistance of the neurons is thought to be overcome in a similar manner.

COCAINISM.

Dr. T. D. Crothers, Hartford, Conn., read a paper on this topic. He said that cocainism appears in two forms, the periodic and the continuous. The principal action of cocain is a stimulation of the brain, producing a sense of exhilaration and a peculiar exaltation of brain activity. The stage of intoxication is marked by great talkativeness, a flow of speech which is in marked contrast with the speech of the alcoholist. Again, the cocainist may be distinguished from the alcoholist by his solitary habits. A significant symptom in the later stages is a sensation of bugs crawling over the skin. The prognosis is always grave. In treating cocainism, the speaker recommended the immediate withdrawal of the drug, and the use of valerian, hyoscyamus and other drugs of that class as temporary substitutes. The patient should be sent away to a sanatorium until the acute symptoms had subsided, and after that should remain for a long time under the constant supervision of his family physician. One cause for the undoubted increase in the use of cocain is that it is sold everywhere without the restraint of law. Other reasons for the spread of cocainism are its reckless use by many physicians, and its presence in many proprietary preparations.

HEART COMPLICATIONS IN RHEUMATISM.

Dr. James J. Walls, New York City, presented in this paper some of the views recently expressed at the International Medical Congress in Paris. He stated that there is little doubt that acute rheumatism is an infectious disease, although its specific cause must be totally different from micro-organisms known at present. The treatment should embrace measures calculated to secure antisepsis of the alimentary canal.

TREATMENT OF PATIENT PRECEDING EXPECTED CONFINEMENT.

Dr. Edward P. Davis, Philadelphia, read the opening paper of the symposium on obstetrics. Commenting on the importance of a careful supervision of the excretory functions, he said that the occurrence of neuralgic disturbance of the cardiac rhythm, changes in temperament, loss of appetite and vague frontal headache, associated with diminished excretion, constitutes a clinical picture of great significance. In the latter part of pregnancy, it is well to limit the consumption of meat to once daily. The presence of serum albumin alone in the urine is of but little significance. When toxemia is present, water should be drunk freely, and it could also be used to advantage in the form of colonic washings. Calomel, in doses of 1/20 of a grain, night and morning, is very useful in increasing the elimination of urinary solids. If sedatives are needed in cases of toxemia, chloral or some derivative of it gives the best results. Walking is a most valuable exercise for pregnant women of all classes of society. A diagnosis of central placenta prævia at any time during pregnancy should be considered a positive indication for the immediate induction of labor.

MANAGEMENT OF NORMAL LABOR, INCLUDING THE USE OF FORCEPS.

Dr. Austin Flint, Jr., New York City, insisted on the pregnant woman taking daily walks up to the time of confinement, the object being to strengthen the muscles, soften the cervix and guard against malpresentations. A thorough pelvic examination, he said, should be made at the end of the eighth month.

OPHTHALMIA NEONATORUM.

Dr. John E. Weeks, New York City, was favorable to the employment of the Credé method of prophylaxis in all cases. The treatment should consist in washing out the eyes every half hour with a 3 per cent. boric acid solution, together with a daily application to the lids of a 1 per cent. solution of nitrate of silver, and the use of cold applications until secretion ceases.

AFTER-TREATMENT OF THE MOTHER IN NORMAL CASES.

Dr. George W. Jarman, New York City, contributed this paper. Attention was called to the importance of the physician's remaining at hand for at least one hour after delivery in order to insure continued firm contraction of the uterus. He saw no objection to urinating in the sitting posture after the third day. It was not generally known that an excessive secretion of milk could be materially diminished by taking coffee. Hemorrhoids were often quite troublesome after labor, but would usually be relieved by cold applications and the use of suppositories containing one grain of ichthyol.

PUERPERAL SEPSIS; ITS PATHOLOGY AND TREATMENT.

Dr. William R. Pryor, New York City, said that autoinfection in puerperal women had been pretty thoroughly disproved, with possibly a few very rare exceptions. The cases could be divided into two classes, septic thrombosis and pelvic lymphangitis. The first class is especially fatal. He mentioned the popular treatment by intermittent washings only to condemn it as inefficient and harmful. Cases of septic thrombosis were the only ones in which he would resort to hysterectomy. He commences treatment by thorough curettage of the uterus and washing out of debris, and follows this by a free incision into the cul-de-sac and evacuation of serum. He then applies a Mikulicz dressing, using a specially prepared iodoform gauze. Cold enemata of salt solution are used every three hours to favor elimination.

TECHNIQUE OF BLOOD EXAMINATION.

Dr. Edward K. Dunham, New York City, opened the evening symposium on the blood by describing the methods of determining the specific gravity and reaction of the blood, and of estimating the quantity of hemoglobin and the number of corpuscles.

LEUCOCYTOSIS IN RELATION TO SURGICAL DIAGNOSIS.

Dr. Joseph C. Bloodgood, of the Johns Hopkins University, discussed the interesting relations of leucocytosis to appendicitis, peritonitis and obstruction of the bowel. He said that in cases of appendicitis the absence of a leucocytosis does not exclude a small abscess, but its presence is almost pathognomonic of absence. A high leucocyte count in the first twenty-four hours of a peritonitis was of little significance, but its persistence after this time made the prognosis more favorable. He had found that intestinal obstruction from any cause is almost invariably followed in a few hours by a rise in the leucocyte count.

PERNICIOUS ANEMIA.

Dr. Alfred Stengel reviewed in this paper the literature, and said he would regard as pernicious anemia a case presenting the usual symptoms of this disease, together with a count of the red blood-corpuscles amounting to 1,500,000, and a proportionate number of leucocytes. By appropriate treatment it was entirely possible to stay the progress of the disease for several years.

LEUKEMIA.

Dr. C. Y. White, Philadelphia, considered leukemia under two heads, namely, splenomyelogenous leukemia and lymphatic leukemia. The anemia of the second variety is less marked, and there is less red cell degeneration and leucocytosis.

PARASITES IN THE BLOOD.

Dr. Leon T. Le Wald, New York City, under this heading, gave an interesting account of the two very recent and famous experiments by which had been demonstrated the positive part played by the mosquito in the malarial infection of man.

VALUE OF BLOOD EXAMINATIONS IN THE DIAGNOSIS OF TRICHINOSIS.

Dr. H. C. Gordinier, Troy, reported in this paper two cases of trichinosis, coming under his observation, which served as additional confirmation of the value of the discovery made by Dr. Brown, Baltimore, that the enormous increase of eosinophiles in the blood is a valuable diagnostic aid in cases of trichinosis.

The following officers were elected: President, Dr. John A. Wyeth, New York City; vice-president, Dr. A. A. Hubbell, Buffalo; secretary, Dr. Frederick Holme Wiggin, New York City; treasurer, Dr. E. H. Squibb, Brooklyn; chairman of committee on legislation; Dr. Irving S. Haynes, New York City; chairman committee on legislation, Dr. E. Eliot Harris, New York City; chairman library committee, Dr. John W. S. Gouley, New York City: chairman committee on public health and medical charities, Dr. Stephen Smith, New York City; chairman committee on nominations, Dr. C. A. Wall, Buffalo; chairman committee on publications, Dr. James Hawley Burtenshaw, New York City. The foregoing constitute the Council of the Association for the ensuing year. The district presidents at present are as follows: First District, Dr. Charles B. Tefft, Utica; Second District, Dr. John T. Wheeler, Chatham, Third District, Dr. Theron A. Wales, Elmira; Fourth District, Dr. William H. Thornton, Buffalo; Fifth District, Dr. J. C. Bierwirth, Brooklyn.

Dr. C. A. L. Reed, president of The American Medical Association, was then introduced to the Association. He said: I thank you for your very cordial greeting, and I accept it as a fealty on your part to our great National Organization which I have the honor, for the time being, to represent. I have peculiar pleasure, however, in meeting you to-day because I discover in your charter, a copy of which has been placed in my hands by your efficient secretary, a proclamation of principles which appeals to me with peculiar force. The first there enumerated, the cultivation of our humane sciences and the promotion of the esprit de corps in our profession, are sufficient in themselves to commend this organization to the enthusiastic regard of every practitioner in this Empire State. Your provision for a death-benefit, which I understand is held under advisement, must, it seems to me, appeal to every one who has a sympathetic cord in his bosom and understands the mutability of fortune. It is the irony of experience that he who often needs succor is the Samaritan himself. This feature of your organization may well be emulated by every state society in the Union.

On this occasion, however, I find myself especially interested in the fourth plank in your platform—that plank which announces as one of your fundamental principles the promotion of harmony, or, as your charter itself says, "the furtherance of cordial professional relations and fellowship between the medical profession of the State of New York and the medical profession of other states of the United States and of foreign countries through the medical associations and societies of such states and countries."

Criticism of that clause must exhaust itself in commendation. It breathes the spirit of harmony, and the spirit of harmony is abroad in the profession, not alone in the State of New York but in the country over. This clause means the union of your noble profession. This clause means that every member of your state organization should become a member of The American Medical Association, and I am delighted to know that many already sustain that relation. This means, as it should mean, that you stand consecrated to an idea above other ideas—the idea of the unity and the solidarity of our great national profession. I know of no object more worthy of your zealous devotion. It simply means that this movement is one on your part that will command the cordial co-operation of the great national body of the profession—not only The American Medical Association, but the great independent body of the profession.

If you stop to think of that independent body you can appreciate its magnitude. Notwithstanding your splendid success in this body—unparallelled in the work of state organization in the United States—and notwithstanding the existence of another state organization in New York State, where the regular profession numbers ten thousand, there are but two thousand yet within the fold of organization. In the United States of America, with an aggregate regular profession of nearly one hundred thousand, there are but ten thousand enrolled in The American Medical Association. There is, therefore, much work in the direction of organization. The spirit is abroad in the land; it will brook no opposition. It is deeply grounded in the sentiment of the general profession, that to be effective at Albany, or Washington, or at the various state capitals, the profession must stand together, man to man and shoulder to shoulder. It ought to take but little time and less effort to accomplish a change that is already accomplished in sentiment. There is not much occasion for the rescinding of resolutions; there is not much occasion for the modification of by-laws or the amendment of constitutions. Possibly some memories may be well effaced, and some conventions that have honorably served their day but are now relatively meaningless. These are subsidiary matters which can well take care of themselves.

He who interposes prejudice, preference or prerogative as obstacles to this consummation is to be looked on and treated as the enemy of progress. I ask, and look confidently, for the cordial co-operation of this great and efficient organization in extending its influence all over the United States. From the remotest districts you will find coming back to you words of cheer, words of encouragement, words of co-operation. The medical profession to-day—and I have reason for the faith that is in me—the medical profession of to-day, the country over, is ready to taken any necessary step, through its organized bodies, that it may present a united front to the dawning century.

(To be continued.)

Chicago Medical Society.

October 10, 1900.

THE CLIMATIC CONDITIONS OF THE SOUTHWEST CORNER OF THE UNITED STATES.

Dr. **Norman Bridge** read the above paper. Climate is wholly a question of atmosphere. The atmosphere is the same everywhere with variations due mostly to local conditions. The variations may be classified under: 1, temperature; 2, moisture; 3, weight of air (barometric); 4, sunshine; and 5, contaminations as of gases, dust and microbes. These variations are due largely to the physical conditions of each region of the earth's surface; and as the latter differ more or less there are no two climates that are exactly alike. The most potent physical factors are: altitude—mountains—latitude, and large bodies of water.

Southern California is divided by a mountain range that, with the ocean, surrounds an irregular half-elliptical region, which has a climate wholly different from that of the desert lands north and east of the mountains. The climate of this coast-mountain region is determined by the three conditions named to a degree hardly found more marked, in any part of the world. The mountain range is four to five thousand feet high; the plateau of habitable land (from 1 to 50 miles wide) has an elevation from sea level to 1500 feet, and rising toward the foothills; the ocean is enormous and cold; and the latitude is nearly as far south as Cairo in Egypt.

As a result of all this the sun warms the land during the day, the air rises by its lightness, air cooled by flowing over the ocean rushes in to take its place all day, making an ocean breeze. The dry air of the mountains and plains causes rapid radiation of heat at nightfall, the stars are brighter there than in this part of the country by reason of the reduced humidity); the air becomes rapidly cooled in consequence, and first cools on the mountains; and by its weight flows down toward the sea most of the night producing a gentle breeze nearly every night, especially in summer. The result of these conditions is a mild, comfortable atmosphere nearly every day throughout the year. The exceptions are an occasional wind in autumn and rather uncomfortably high temperature in some of the more inland foot-hill regions a few days in summer. Without the peculiar arrangement of mountain and ocean with habitable land between, Southern California with its far south latitude, from being one of the most comfortable regions for a residence winter and summer in the world, would be a most uncomfortable one except in winter.

The desert region north and east of the mountains is very dry and very warm in the summer, although not uncomfortable in winter. Heavy rains fall irregularly, more often in the summer, but the air is usually very low in humidity and altogether the climate is totally different from that of the zone on the other side of the mountains.

The highlands of Arizona are arid and comfortable both winter and summer. The regions of low altitude, especially far south, are in summer too hot for comfort.

The statistics as to physical conditions of the southwest corner are interesting when compared with those of the east. The mean temperature of Southern California is higher than Chicago by about four degrees Fahrenheit in summer and thirty degrees in winter. The relative humidity is lower by 5 to 10 per cent., but the actual humidity is higher than in any region east of the mountains. The cloudiness is only two-thirds as much as that of the region about Chicago; the rainfall is a third or less than that of the Mississippi Valley.

One of the most remarkable atmospheric conditions is the slight range of the barometer; that of Los Angeles being only 14/100 of an inch, while that of Chicago is over 56/100.

The actual temperature of the whole southwest region ranges higher than the east by several degrees and most in summer, but the sensible temperature, that which is actually perceived by man, is seven and one-half degrees Fahrenheit less than that of the east. This is wholly due to the reduced relative humidity—the percentage below saturation.

Fogs abound in certain regions, especially nights and early mornings. They simply mean a sudden drop in temperature so that saturation is reached. The sunshine soon warms the air and redissolves the fog. As the chilling of the warm clear air is usually by a cold ocean current containing much less actual moisture, the mixed air of the fog usually has less water than the warm air did before; hence a curious paradox of wet cloths and dripping roofs with less absolute moisture than before the fog appeared. It is only a small part of the time that humidity is 100 per cent.

The physical discomforts incident to weather, of a continuous residence in Los Angeles, are about a quarter what they are in Chicago—yet people there growl at a disagreeable day. Thermic fever is practically unknown, as is hydrophobia, and in nine years there I have yet to see a case of lobar pneumonia, non-tubercular.

Southern California is the paradise of children and old people—the former thrive and have many fewer infantile diseases than here; the latter piece out their lives as they can not anywhere else in the world.

Of course, the greatest number of cases of disease migrating thither are of tuberculosis and many of these recover; so many that it strongly supports the theory that neither great altiude nor great dryness of air is of half as much value as the ability to live day and night in an outdoor atmosphere.

Many cases of chronic articular rheumatoid diseases find their way there and nearly all get better.

Cases of chronic bronchitis and asthma are nearly all more or less benefited.

THE FATE OF SPONGES, LIGATURES AND OTHER FOREIGN BODIES IN THE PERITONEAL CAVITY.

Dr. **Carl Beck**, after reviewing the literature on the subject, which covers experiments, as well as experiences during and after operations, adds two cases of sponges left in the abdominal cavity by him to the number already published. In one the sponge caused an abscess which opened into the incision. In the other, it was discharged through the bowel. He cites three typical cases of silk ligatures sloughing through into the bowel, the bladder, and uterine cavity. Such cases may puzzle the operator, especially as a number of the most pexplexing symptoms obscure the diagnosis. Serious consequences may follow the sloughing of sutures into hollow organs like the bladder, the lung, or even the intestine, but, as a rule, they are more marked by a tedious, protracted ailment of an indefinite character. Hemorrhage from the intestine is a very characteristic symptom, and led Dr. Beck to suspect in one case a forgotten sponge which was verified afterward by experience.

His conclusions are: 1, Silk ligatures are not as harmless as they are usually regarded. 2. Absorbable material should be preferred. 3. If unabsorbable material is used, small and interrupted sutures should be employed. 4. It takes less time for the interrupted one to slough out. 5. A way out is to be prepared if ligature suppuration is suspected. 6. Even catgut may cause such symptoms.

ELIMINATION OF THE INFLAMED,, GANGRENOUS, OR PERFORATED VERMIFORM APPENDIX FROM THE GENERAL CAVITY.

Dr. **A. J. Ochsner** points out the fact that the vermiform appendix is located in the peritoneal cavity in a spot bounded by relatively fixed areas on all except the inner side, and that on this side lie the exceedingly movable small intestines; also that the appendix is surrounded by the omentum as soon as it becomes inflamed or gangrenous, or in case a perforation is threatened. If this condition can be maintained throughout the attack it is plain that the appendix will be practically eliminated from the peritoneal cavity. Experience has shown that this condition of rest is disturbed only by peristaltic motion, and that this occurs only as a result of placing food or cathartics in the stomach. Consequently, if neither food nor cathartics are given by mouth this condition of rest will not be disturbed, unless there is present at the beginning of the attack an amount of food in the stomach. It happens frequently that an attack follows the taking of a large meal. In this case, the stomach should be irrigated and its contents removed.

This will stop the vomiting and will inhibit peristaltic motion.

The author advises the use of some concentrated, predigested food, diluted with normal salt solution, for the purpose of rectal alimentation, in quantities not to exceed four ounces at intervals of four hours. This treatment, which is continued until the patient has been free from symptoms for at least four days, will not protect the patient against a recurrence, nor against the very troublesome digestive disturbances due to the adhesions following appendicitis, but it will carry the patient safely over an acute attack changing what threatens to be a dangerous diffuse into a comparatively harmless circumscribed peritonitis; enabling the surgeon to select a favorable time for operation.

The paper contains a series of consecutive histories illustrating the plan of treatment and its results. In the author's hands this method has reduced the mortality in cases of inflamed, gangrenous or perforative appendicitis to one-fourth of that formerly experienced in his practice.

TWO INTERESTING CASES OF APPENDICITIS.

Dr. A. R. Small reported these mainly because of the peculiar position and investments of the appendix in both of them. He had not been able to find the report of a similar case in the voluminous literature of appendicitis, nor has he been able to find any one who has seen a similar case. The peculiarity in common in the two cases consisted in the location and investments of the appendix. The appendix was unusually long in both cases, being six inches long in one and five in the other. The appendix in both cases was turned backward and upward along the band of longitudinal fibers of the cecum and colon, and covered by the same peritoneal coat as the bowel, except in one case, one inch of the distal extremity, and in the other one-half inch. There was no mesentery in either case, but the appendix lay in intimate contact with the posterior surface of the bowel along the band of longitudinal fibers, and the peritoneal coat invested both the bowel and the appendix, so that it was almost impossible to discover the appendix except by its free distal extremity. This condition was not due in either case to inflammatory exudate and adhesions, but was evidently congenital. The author then narrated the two cases in detail.

The cases were interesting also on account of one being of so serious a nature, yet manifested mild symptoms; and the other from the fact of having had so many attacks without more serious results. In one the first attack would probably have been fatal without an operation; in the other there were many attacks without producing a fatal result.

Dr. Harold N. Moyer believes that the method outlined by Dr. Ochsner is based on correct scientific principles. While he has seen but a few cases of acute appendicitis, he has witnessed a large number of chronic ones. While he would condemn in unmeasured terms operation in the early stage, unless done very early, when these cases are rarely seen, in the acute stage, he would just as firmly and enthusiastically urge operation on all chronic cases. After the acute stage has passed the appendix should be removed.

Dr. William M. Harsha said that any method of treatment which would give only 8 cases of death out of 248 patients deserved more than a passing notice. However, he believes that the method of Dr. Ochsner is no more applicable to every case than any other method that has ever been devised. In cases of fulminating appendicitis in which perforation takes place, it requires a great stretch of the imagination to see how opium and starvation would limit the sepsis so as to make it safe for the patient without operation. He believes there are a number of cases of fulminating appendicitis which should be operated on as soon as the diagnosis is made.

Dr. Fenton B. Turck recommended colonic lavage, saying that by it the fecal matter could be removed without increasing the peristalsis of the entire alimentary tube, without overstretching the colon, and obtaining the heat stimulation necessary for the purpose of removing gases and lessening pain. After lavage of the colon it is much easier to make an accurate diagnosis.

Dr. William E. Schroeder referred to the medical statistics of appendicitis, saying that out of 7000 cases cited by one author no reference was made to complications. The complications are abscess of the liver, septic pleurisy and other forms of suppurative disease. He has seen three or four cases where the appendix was removed before perforation had taken place.

Dr. W. T. Eckley has seen only two cases where the appendix was esconced between the two layers of the mesocecum out of 400 appendices in cadavers during the last five years. In both the mesocecum was very short. The cecum was located high in the right iliac fossa.

Dr. J. N. Bartholomew, in operating on a case of appendicitis recently, found the appendix situated in the posterior part of the cecum. its lower half being covered with peritoneum. The appendix was eight inches long, and extended up in the direction of the liver. The end of the appendix, in which the abscess was situated, lay in close contact with the gall-bladder.

MYASTHENIA GRAVIS.

Dr. Sanger Brown reported a case. The patient was a teacher, with good family history. Nervous temperament. After having attended a social function several months previously, there was muscular exhaustion on slight exertion, so that it was with difficulty that she was able to move her arms and legs. Diplopia and ptosis became troublesome; the voice nasal and articulation imperfect. Occasionally there was humming in the ears and pains throughout the body, but the latter were infrequent and trivial. Mucous membranes of the mouth and nose were uncomfortably dry at times; hair and scalp very dry. Skin has remained in good condition. Appetite, digestion, sleep, etc., were satisfactory. Habitual constipation was somewhat aggravated. Very little mental depression existed. After a short walk there is not enough strength for the patient to cross her legs when sitting. Patient has lost fifteen pounds in weight since illness. Reflexes are lively, but normal; voluntary motion in every direction. No inco-ordination is present. Strength was greatly reduced. No suspicion existed of muscular atrophy or deformity; no pain or tenderness on pressure. There was no evidence of hysteria.

After detailing the other symptoms in this case, Dr. Brown referred to the literature of other cases and dwelt on the differential diagnosis between myasthenia gravis and hysteria, as well as other affections.

Dr. Henry B. Favill said he had seen one case which he believed could be designated as myasthenia gravis. The patient was 47 years of age. Toxic neurasthenia was one of the many manifestations occurring in a gouty family, and after a period of eighteen months the patient gradually recovered to the point of reasonable health and capacity. After a period of six months of good health the patient began to deteriorate and manifested in the course of the second year what he considered to be typical progressive bulbar paralysis, and he thought the patient would soon succumb. After going through a period of exaggerated symptoms the patient again apparently recovered, in that the typical signs of bulbar paralysis disappeared; she regained facility of speech, was able to swallow, vision was improved, etc., and yet in the course of the next nine months she developed a distinct myasthenia without ptosis, but more or less insufficiency of the ocular muscles, together with profound asthenia of the bodily muscles, so much so that when she fell on the floor, as in rocking, she was unable to get up. The patient was large. She went through this period of profound asthenia without dystrophy, without paralysis of any sort, without atrophy of any groups of muscles, and developed later, in the course of a year—and by this time the case covered a period of four years—a typical bulbar paralysis, and died finally of acute edema of the lungs.

Dr. Daniel R. Brower said that he had seen two cases in which he had made a diagnosis of myasthenia gravis, although he had been in the habit of calling the disease asthenic bulbar paralysis. In both of the cases the myasthenia began with the third, fifth and seventh nerves. followed by general debility of the whole muscular system, associated with slightly exaggerated patellar tendon reflexes that were easily exhausted. The electrical reactions were not determined. Muscular atrophy finally developed, the cranial nerves becoming involved, and the patient dying of bulbar paralysis.

The second case, which presented similar symptoms, recovered. In this case small doses of strychnia were used in conjunction with the constant galvanic current through the head, neck and spine.

Dr. Harold N. Moyer had seen one case which he believes could be included in this category, but the clinical course was more rapid, the time of onset of the affection until the death of the patient being about four months. There were two distinct remissions. The paralytic trouble and myasthenia, which were most marked, began in the lumbar portion of the cord instead of the upper part, ultimately affected the upper portion of the cord, involving the respiratory center and followed by death.

The Kings County Medical Association.

Stated Meeting, October 9, 1900.

President Dr. H. Arrowsmith in the chair.

THE BIO-CHEMICAL BASIS OF PATHOLOGY.

Dr. H. A. Bunker read a paper with this title. He said that in 1898 he had read a preliminary communication on this subject before another medical society. We must go back of structure and form for the origin of disease; in other words, nutritional disturbances and perversions must antedate changes of structure from the normal. In the normal cell, the nucleus resembles in every respect morphologically, and as far as known, chemically, all other cell nuclei. The same number of chromatin filaments persist throughout. If there is any distinguishable difference in the nuclei, we must look into the material built up by the cell protoplasm. We are obliged to assume the existence of a selective affinity in the cell protoplasm for certain nutritive substances. The solution of the problems involving growth, waste and repair must rest on the quality of the building material required, the character of the structure to be built, and the means for disposing of waste products. Reference was made to the well-known Pasteur's medium for the culture of yeast cells, and special attention was called to the fact that the sugar in this medium undergoes a molecular change as shown by the change in its behavior when subjected to polarized light. This change, the speaker said, he had observed under many other conditions, and he believed it contained a clue to the solution of some of the deepest problems in biology. As in the yeast cell, so in all organic life there was abundant reason for believing that none of the food stuffs is used in the body as such, but only after having been subjected to complex dehydration and oxidation processes. Fats and carbohydrates are stored for use in emergencies as required by the organism. The ultimate fate of fat in the body is its splitting up into carbonic acid and water with the production of heat and energy, whether physical or molecular. This process is a continuous one, and occurs throughout living proteid substances. The particular character of a structure seems to be dependent on the predominant niltrogenous or fatty acid or group of fatty acids. Volatile fatty acids are apparently those which have not been built into proteids. Fat probably has its origin in the synthetic activity of protoplasm. Very little is known of the methods by which the stored-up fat is drawn upon and assimilated by the system when the emergency arises. Lymphoid cells are notably active in all the processes of anabolism, and it is probable that these cells bring about the necessary changes in the stored up fat to render the latter suitable for assimilation. All the tissues are supplied with lymphatic vessels and glands and lymph spaces, hence it is probable that the waste of one organ serves to provide the raw material for another organ. The waste products of each tissue or organ need not be the end-products of the body at all, but certainly are the antecedents of these. The different forms of pathological degeneration would seem to depend on imperfect hydrolysis. The amido acids are never found combined with glycerin as are the free acids themselves. Aldehyde is always a cleavage product of proteid decomposition. Like glycerin, and its derivatives, the fatty acids, the amido acids, are never found free under normal conditions. The speaker thought he had found that in the fibrosis which occurs in the healing of tuberculosis, amido-succinic or sparteic acid is present. Certain recent experiments seem to show that in tuberculosis succinic acid plays an important part. Dr. Bunker expressed his belief in the existence of asymmetric forces at the moment of liberation of organic products. Under physiological conditions, lines of cleavage, synthetic re-arrangements and sucessive oxidations follow a well-defined and symmetrical sequence. If these are disturbed, the result is a pathological process. If after normal cleavage imperfect oxidation takes place, or if after imperfect cleavage normal oxidation takes place, morphological changes will take place. On these theoretical considerations must depend largely the therapeutics of the future.

Dr. Jacob Fuhs said that one could not possibly follow life processes in disease without searching for a better understanding of the physiological. These had been brought forward in the paper. It should be remembered that each living cell of an organism is undergoing a constant change, a change which is particularly active in the protoplasm. The nucleus must also participate in the nutritional change, this cell being, as it were, an organism by itself so far as nutrition is concerned. We had just been told that the cell was even able to appropriate for its ends the fat stored up around it. Again, certain cells seem to conspire to help other particular cells. His attention had been directed to this by a study of the visual purple. This substance is probably intended to protect the very sensitive structures of the eye and assist in accommodation—at least that is the statement in the latest text-book on physiology. To him this explanation did not seem plausible, as it was known that the visual purple disappears at the time when protection is most needed. To his mind it was more reasonable to suppose that this visual purple plays a role similar to that of the stored-up fat. In the aromatics was to be found a substance which disturbs the nutrition of the cell, and leads to the production of uric acid. For the last few years the view has been held that the defect lay in the nucleus rather than in the protoplasm. According to this theory, albumoids can be given in uric-acid diseases as long as they do not contain xanthin, and the quanity is moderate. By cooking meat with cereals the aromatics are not formed as freely as by the ordinary method of cooking. Such meat is comparatively insipid, but the dangerous extractives have been for the most part eliminated.

Dr. J. M. Van Cott said that while the nuclei of all cells are alike originally, this equality does not continue. In a recent article, Kassowitz had claimed that the chemical activities are not restricted to the nucleus or the body of the cell, and even claimed that the connective tissue is just as vital as the nucleus. The enzymes are thought to be different in their nature, depending on whether they are in the cell or in the nucleus or in the connective tissue. He heartily agreed with the reader of the paper that morphology must now give way to the still higher branches, physiological and pathological chemistry. That this is the case was well exemplified by common experience in the laboratory that certain standard stains act in one way with normal tissues and in a different way with those which are the seat of pathological processes.

Dr. Bunker, in closing, said that he had characterized the nucleus as a selective and determining factor, its activity taking place not only throughout the protoplasm, but throughout the fluids bathing the tissues and cells.

The Cincinnati Academy of Medicine.

Regular Meeting, Oct. 1, 1900.

President Dr. C. L. Bonifield in the chair.

Dr. R. B. Hall presented a specimen of multilocular fibroid tumor of the uterus, the greater part of one of the tumors of which had undergone calcification.

VERMIFORM APPENDIX ADHERED TO UTERUS.

Dr. A. W. Johnstone reported a case of a woman who had been afflicted with severe dragging pain on walking. This had annoyed her so greatly that she had herself demanded operation, though nothing could be found on examination to warrant operative interference. Section had disclosed an adherence of the end of the appendix to the uterus, and the former was put on the stretch with every movement of the body.

ETIOLOGY AND PATHOLOGY OF CARCINOMA.

Dr. Frank E. Fee stated that a lack of knowledge of the cause of cancer was the great obstacle to a proper cure; that it was thus rendered the most dreaded of all diseases. Not only was it greatly feared, but rightly so, as, according to Roswell Park's statistics, the disease was so rapidly increasing that if it continued at its present rate of rapidity in 1909 there would be more deaths from cancer in the State of New York than from tuberculosis, smallpox and typhoid fever combined. He then reviewed Cohnheim's theory of embryonic remains, but personally was inclined to reject it as not fitting all the facts, in other words, "not proven." The points of complicated development, the lips, tongue, pyloric and cardiac ends of the stomach, were also the parts of the economy subjected to the greatest irritation. He was inclined to accept a parasitic origin of the disease for the following reasons: Malignant growths present a close resemblance to certain of the infectious diseases—such as tuberculosis—in their obscure origin, tendency to spread locally, and dissemination by lymph and blood paths; the occurrence of secondary deposits in various parts of the body; that they often follow an injury or blow, or at the site of an old cicatrix, that is to say, a point where physiological resistance is below par; the existence of a toxemia, as shown by fever and cachexia, and often out of proportion to the size and situation of the tumor.

He called attention to the recent investigations in England, in which certain portions of the country had been mapped out where cancer was particularly present; these were known as cancer fields, and were usually situated in the low lands, on the banks of sluggish streams, as well as those subjected to frequent floods. This observation, he thought, might at some future time, be of considerable value. The essayist then described at some length the announcement of alleged discoveries of a parasite of cancer and laid particular stress on the reports of the New York Laboratory. Then followed a description of the parasite and the various methods of fixing and staining according to his own observations and those of Plimmer. Experiments in cultivating the parasite have not been entirely satisfactory. Both Plimmer, of England, and Park, of New York, claim to have succeeded. Their cultures inoculated into guinea-pigs produced death in from fifteen to twenty days. The peritoneum, into which the cultures were injected, was found studded with small transparent nodules, as were most of the other internal organs. Microscopically they were of endothelial origin. The cells were found to contain the organism. The production of cancer has not been satisfactory when these organisms have been brought into contact with epithelial surfaces. To cultivate the organism cultures of ordinary beef infusion are made to which is added after careful neutralization 2 per cent. of glucose and 1 per cent. of tartaric acid. Into this very small pieces of the growth, cut with all possible precautions against contamination, were placed, and the tubes put immediately under anaerobic precautions, the air being exhausted and hydrogen substituted for it. In conclusion the essayist stated "At present I am not prepared to state fully the results of my investigations in this line, but will say that I have only twice failed to find these bodies described, and that I have never found them in any other tissue than cancerous. I have always failed in cultivating the parasite to my own satisfaction. While I agree that the parasitic theory of cancer can not be accepted until it is unmistakably proved that a malignant growth can be produced by an organism isolated from a cancer, it is to be hoped that work in this line will be continued so that collective investigation can be well established. It is my intention to bring this subject before the Academy in the near future, and I hope to at least assist to establish the claims made by other observers in regard to cultivation and inoculation.

The paper was discussed by Drs. A. Friedlander, J. Ransohoff, Joseph Eichberg, A. Freiberg and A. W. Johnstone.

EARLY DIAGNOSIS OF CANCER OF THE UTERUS.

Dr. John P. Miller stated that the principal symptoms were hemorrhage, pain, discharge and cachexia; that hemorrhage was the first symptom to present itself. It usually attracts attention in a woman who has been menstrating normally as a slight show of blood, occurring after violent exercise, a severe jar, or especially after coitus, rather than as an increase in frequency or profuseness of the menstrual flow. In women who have ceased menstruating the reappearance of the flow may lead them to the belief that this function is being reestablished. It is unfortunate that the hemorrhage is not more severe in the early stages, as in this case the woman would be more likely to consult her physician, and her condition be diagnosed while yet in a comparatively early stage. The hemorrhage which first occurs in cancer of the uterus, like the early hemorrhage produced by fibroid comes from the accompanying hypertrophic endometritis, and not as the result of ulceration. Pain is the next symptom to manifest itself, but it does not become prominent until the disease has made considerable headway. The severe pains we are accustomed to associate with carcinoma uteri are produced by the efforts of the uterus to expel clotted blood and detritus, by involvement of the peritoneum and by pressure on the nerves of the pelvis, conditions that do not exist in the early stages of the disease. Pain, as a rule, manifests itself in the sacral or lumbar region. It usually differs in no way from that produced by other uterine disease, but occasionally occurs in paroxysms at certain times of the day, and this paroxysmal pain is a diagnostic symptom of some importance when present. Early in the disease the discharge is leucorrheal, of endometrial origin, and not distinctive; later it becomes thin, watery, irritating and fetid. Cachexia, as a rule, is the last of these cardinal symptoms to appear. The essayist then called attention to the value of the microscope in the early diagnosis of the disease.

He stated that carcinoma uteri usually took its origin from one of three places: The portio, the cervical canal and the body of the uterus. Carcinoma of the portio is either of the pavement epithelial variety or the cylindrical-celled variety, and has to be differentiated from decubitus ulcer, erosion, tuberculosis, chancre and chancroid. An elaborate table for the differentiation of these diseases followed. Cancer of the cervical canal is the most frequent of all cancers of the uterus. The varieties are the same as in cancer of the portio, but more frequently cylindrical. Cancer of the body of the uterus is the least frequent of uterine cancers, and develops either from the epithelium of the glands in the mucous membrane or from the epithelium between the glands.

Microscopically we can distinguish three forms of cancer in the body of the uterus, the malignant adenoma, the adenocarcinoma and the simple carcinoma. The essayist then reported a case that had presented itself at his clinic last winter. The patient was 32 years of age, the mother of several children, stout and well-nourished; complained of pain in the back, leucorrhea and excessive menstruation. On examination, the cervix was found normal, the uterus itself somewhat enlarged, freely movable, but could not be freely palpated on account of the thick abdominal wall. She was sent to the Good Samaritan Hospital and curettage performed. Microscopical examination showed the scrapings to be from an adenomacarcinoma (a specimen was shown under the microscope by the essayist). A subsequent hysterectomy showed a cancer about the size of a ten-cent piece situated on the posterior wall of the uterus. Cancer of the body of the uterus is to be differentiated from hypertrophic endometritis with enlargement of the uterus, from subinvolution, from sloughing fibroid and from retained products of conception.

The paper was discussed by Drs. R. B. Hall, C. D. Palmer, S. P. Kramer, Whittacre and Brown.

Therapeutics.

To Abort Pneumonia.

℞.	Acetanilidi	ʒi	4	
	Pulv. opii et ipecacuanhæ	gr. xxxvi	2	40

M. Ft. chartulæ No. xii. Sig. One powder every four hours, day and night.

J. Paffrath, in *Deutsche Med. Zeit.*, states that he has never failed to abort the beginning of pneumonia in from five to six days with the above treatment. He goes on the basis that pneumonia is not of bacterial origin. He orders the powders stopped as soon as the temperature drops.

Epileptiform Convulsions Due to Autointoxication.

R.	Ext. chiratæ	gr. ii		12
	Leptandrin	gr. ss		03
	Podophyllin	gr. 1/5		012
	Creosoti (beechwood)			
	Euonymin, āā	gr. ss		03

M. Ft. pil. No. i. Sig. *One such after each meal.*

—Hare: *Medical Record.*

Urticaria.

℞.	Ethylis alcoholis			
	Etheris sulphurici			
	Chloroformis, āā	℥i	32	
	Mentholis	gr. ii		12

M. Sig. Apply as a lotion. —Gaucher: *Med. Record.*

Seminal Emissions With Erections.

℞.	Strychninæ sulphatis	gr. i		06
	Acidi phosphorici diluti	℥ii	64	

M. Sig. Twenty-five drops in water after each meal.

—B. K. Twitchell.

Blueberry in Intestinal Inflammations.

℞.	Ext. myrtillus berries	℥i	32
	Potassii carbonatis	gr. xlv	3
	Aquæ destil	ʒiss	6
	Cacao butter	℥ii	64

M. Ft. suppos. No. xxx. Sig. Two to be used daily.

Dr. H. Strauss, in *N. Y. Med Jour.*, recommends this combination as an astringent in intestinal inflammations.

Amenorrhea.

℞.	Strychninæ sulphatis	gr. iss		1
	Acidi oxalici	gr. viiss		5
	Ferri peptonatis			
	Manganese lactatis, āā	ʒii	8	
	Ext. colocynthidis comp	gr. xxx	2	

M. Ft. capsulæ No. lx. Sig. One capsule three times a day, after meals. —H. C. Bloom.

Hemorrhoids With Pain.

℞.	Morphinæ sulphatis	gr. vi		4
	Cocainæ muriatis	gr. xii		75
	Hydrargyri chloridi mitis	gr. xl	2	66
	Vaselini	℥i	32	

M. Sig. Apply locally night and morning.

Sawyer states that this combination is the best local application that can be made when pain is present. If itching is present, or in cases of pruritis, he recommends:

℞.	Menthol	ʒss to ʒi	2-4
	Vaselini	℥i	32

M. For local application, night and morning.

Cough of Influenza.

℞.	Sodii benzoatis	ʒi	4	
	Bromoformi	m. x		66
	Syrupi tolutani	℥i	32	
	Syrupi lactucarii	℥iii	96	

M. Sig. One tablespoonful every four hours.

—Le Moine: *Bul. of Ther.*

Ringworm.

℞.	Epicarin		
	Talci veneti		
	Amyli, āā	ʒi	4
	Vaselini	ʒiii	12

M. Ft. unguentum. Sig. For external use.

—*Jour. de Méd. de Bordeaux.*

Anaphrodisiac.

℞.	Lupulini	ʒiiss	10

Ft. capsulæ No. xv. Sig. One capsule at bedtime.

—*Med. Times and Gazette.*

Dental Caries.

℞.	Acidi carbolici		
	Essentiæ limonis, āā	ʒi	4
	Alcoholis	ʒv	20

M. Sig. Wash and dry the cavity; soak a small pledget of cotton in this solution and insert into the tooth cavity and cover with tincture of benzoin on cotton.

—*Gaillard's Med. Journal.*

Malarial Cachexia.

℞.	Quininæ sulphatis	ʒi	4
	Tinct. ferri chloridi	ʒv	20
	Liquoris acidi arsenosi	ʒiss	6
	Potassii chloratis	ʒi	4
	Syrupi zingiberis, q. s. ad	℥iv	128

M. Sig. One teaspoonful, in water, three times a day.

—Dr. Guice: *Med. Fortnightly.*

Acute Nephritis in Children.

℞.	Tinct. aconiti	ʒss	2	
	Codeinæ	gr. ii		12
	Potassii citratis	℥iii	96	
	Glycerini	℥ii	64	
	Aquæ cinnamomi, q. s. ad	℥viii	256	

M. Sig. One teaspoonful every two hours in half a glass of pure water.

—Danforth: *Amer. Text-Book of Dis. of Children.*

Acute Catarrhal Laryngitis in Children.

℞.	Tinct. aconiti	gtt. viiss		5
	Sodii benzoatis	ʒss	2	
	Cherry laurel water	ʒiiss	10	
	Syrupi codeinæ—gr. 1 per ℥	ʒii	8	
	Syrupi aurantii	ʒv	20	
	Mucilaginis acaciæ, q. s. ad	℥iv	128	

M. Sig. One to two teaspoonfuls every hour, according to the age. —Perier: *Pediatrics.*

Irritability of the Bladder After Delivery.

℞.	Salol		
	Tinct. hyoscyami, āā	ʒii	8
	Infusi buchu, q. s. ad	℥vi	192

M. Sig. Shake. One teaspoonful three times a day.

℞.	Liquoris potassæ	ʒi	4
	Mucilaginis acaciæ	℥ss	16
	Tinct. hyoscyami, q. s. ad	℥ii	64

M. Sig. One teaspoonful three times a day.—Fothergill.

Constipation in Children.

℞.	Sodii bicarbonatis	ʒiii	12	
	Pulveris rhei	℥ii	64	
	Sodii sulphatis	℥i	32	
	Olei menthæ piperitæ	gtt. xx	1	33

M. Sig. One-half to one teaspoonful of this powder may be given in the morning before breakfast.

℞.	Mannæ	℥i	32
	Magnesiæ—calcined		
	Sulphuris sublimati, āā	℥ii	64
	Mellis	℥i	32

M. Sig. From a teaspoonful to a tablespoonful dissolved in a cup of hot milk, night and morning. —*Jour. des Prac.*

To Lessen Labor Pains.

R.	Lactis	fl℥i	32
	Chloralis hydratis	gr. xxx	2
	Aquæ destil	℥i	32

M. Sig. To be used as an enema during the first stage of labor. —*Monthly Encyc. of Med.*

Early Cough and Fever in Pneumonia.

℞.	Potassii citratis	ʒvi	24
	Spts. etheris nitrosi		
	Tinct. opii camphoratæ, āā	ʒiv	16
	Liq. potassii citratis, q. s. ad	℥vi	192

M. Sig. One dessertspoonful every three hours.

—Hughes: *St. Louis Clinique.*

Acute Pharyngitis.

℞.	Tinct. aconiti	m. vi		36
	Sodii salicylatis	ʒii	8	
	Aquæ menthæ viridis	℥iii	96	

M. Sig. One teaspoonful, undiluted, every hour.

Of use in acute pharyngitis with moderate fever.

To Keep the Hands in Good Condition.

℞.	Olei rosæ	m. xv	1	
	Glycerini	ʒi	4	
	Spts. myricæ	ʒiii	12	
	Olei cajuputi	m. xx	1	33

M. Sig. Apply to the hands before retiring, first washing them thoroughly in hot water. —*Calif. Med. Journal.*

Phosphaturia.

℞.	Ammonii benzoatis	ʒiv	16	

Place in cachets No. xxiv. Sig. One cachet after meals.

Indications—In phosphaturia with ammoniacal urine.

—*Dominion Med. Monthly.*

Expectorant Mixture.

℞.	Ammonii chloridi	ʒi	4	
	Potassii chloratis	gr. xxiv	1	66
	Ext. glycyrrhizæ	gr. xxx	2	
	Spts. etheris nitrosi			
	Syrupi seneg, āā	ʒii	8	
	Aquæ cinnamomi, q. s. ad	℥ii	64	

M. Sig. One teaspoonful every four hours.

—*Druggist and Review.*

Gonorrheal Epididymitis.

℞.	Methyl salicylatis	℥i	32	
	Olei olivæ	℥ii	64	

M. Sig. Apply to the scrotum and protect by gutta percha paper and a suspensory bandage.

Bettman advocates the above treatment and advises the change of dressings every two hours. That the salicylate is absorbed is proved by the urine. —*Med. Age.*

Ocular Neuralgia.

℞.	Morphinæ sulphatis	gr. iv		25
	Chloralis hydratis	gr. x		66
	Cocainæ hydrochlor.	gr. xx	1	33
	Menthol	gr. xxx	2	
	Lanolin	℥i	32	

M. Sig. Apply a piece the size of a hazel-nut to the temple and over the brow every hour until relieved. —Fox.

Nasal Obstruction in the Newborn.

℞.	Resorcin	gr. xv	1	
	Olei vaselini	℥iss	48	

M. Sig. Drop three or four drops into the nares three or four times a day.

Or,

℞.	Sodii biboratis	ʒiss	6	
	Glycerini	℥i	32	

M. Sig. Hold the head well back and allow three or four drops to enter the nares on either side and repeat two or three times during the day.

M. Leopold Cheauveau states that when acute coryza is the cause of nasal obstruction in the newborn he has found the above to be very efficient. —*Practitioner.*

To Prevent Loosening of the Teeth.

℞.	Acidi tannici	ʒii	8	
	Tinct. iodi	ʒi	4	
	Potassii iodidi	gr. xv	1	
	Tinct. myrrhæ	m. lxxx	5	33
	Aquæ rosæ	℥vi	192	

M. Sig. A teaspoonful in water to rinse the mouth every two hours. —*Practitioner.*

Taenifuge.

℞.	Acidi salicylici	gr. viss		4
	Oleoresinæ aspidii	gr. x		66
	Olei cinnamomi	m. x		66
	Gum arabici	ʒii	8	
	Aquæ	℥ii	64	
	Syrupi simplicis, q. s.	℥iii	96	

M. Sig. To be taken in two doses before breakfast.

—*Phar. Post.*

Cleansing of Teeth.

℞.	Pulveris cereal	ʒiiss	10	
	Sodii boratis	gr. xxxvi	2	4
	Potassii chloratis	gr. xv	1	

M. Flavor with orris and menthol. Sig. For cleaning teeth.

Dr. Fletcher, in the *Cincinnati Lancet-Clinic*, states that the object is to keep the saliva decidedly alkaline for some time after using and to counteract the ill effects of sweets. It is preservative and antiseptic and will retard decay.

Anemia With Dysmenorrhea and Constipation.

℞.	Ferratini	ʒii	8	
	Pulv. rhei radicis	ʒiv	16	
	Sodii bicarb.	ʒii	8	
	Ol. fœniculi	gtt. xxx	2	

M. Sig. Take a teaspoonful at night, in a wafer or dry on the tongue, and wash down with water. —*Med. Fortnightly.*

Ferratin is an organic compound of iron made from the liver of the hog.

Medicolegal.

May Refresh Memory on Question of Age.—The Supreme Court of California holds, in People vs. Vann, a prosecution for an assault with intent to commit rape on a female under the age of consent, that, where a physician was called as a witness and stated that he attended the mother of the girl at the time of the latter's birth, it was proper to allow him to refresh his memory as to the date of her birth, so as to show her age at the time of the alleged assault, by an entry in his cash book, he having testified that he made the entry at the time he attended the mother at the birth of the girl, and that by the entry he knew the date of her birth.

Number of Expert Witnesses Not Controlling.—Numbers in experts, the second appellate division of the Supreme Court of New York declares, in the same of Simonsen vs. the Brooklyn Heights Railroad Company, are not more controlling than numbers in ordinary witnesses. Where they advance two opposing theories, it is the function of the jury it says to decide between them. Nor is it concerned here about whether the jury thought that the opinions of the plaintiff's physicians were colored by professional partisanship, or were unfounded on the facts, or were exaggerated, or were those of alarmists, and that the opinion of the opposing physician was the wisest or was more warranted by the facts. There was conflicting evidence and there was clash of opinion, and the court holds that it was not called upon to upset the result by the test that, if it had been sitting as a jury, it would have returned a different verdict.

A Large Award for Injuries to Boy.—A boy 11 years of age, who lived with his widowed mother and was attending a public school in the neighborhood of her residence, was run over by a street car. He was so badly injured by the accident that he was compelled to suffer two amputations—the first, removing the lower portion of the left leg at a point about three inches below the knee-joint, and the second operation destroying the knee-joint and all below it. An action for damages followed, which resulted in a verdict for $22,500. Complaint was made that this was excessive, but the second appellate division of the Supreme Court of New York holds otherwise, Williamson vs. Brooklyn Heights Railroad Company. In support of this, it says that it is manifest that the pain resulting from the injury and following the two amputations was extreme, and that the permanent disability arising from the loss of his leg will put the boy at a serious disadvantage, physically, when he arrives at manhood and enters into the competition of life. Besides, it says, as large verdicts as this for similar injuries to children have in some other cases been sustained.

Between Buyer and Seller of Medical Practice.—A physician contracted to deliver certain real estate and the good-will of his business, so far as such good-will could be delivered. To better accomplish this latter object, he agreed to form with the purchaser a partnership for a stated period, to introduce him to his patrons, to send him to answer all calls possible, and to himself attend such cases as he might be personally insisted on attending. Now, these obligations of the seller, as to the real estate and the good-will, the Supreme Court of Illinois holds, case of Tichenor vs. Newman, were personal to the purchaser, and their non-performance vested a right of action in him. Consequently, he could sue, in an action at law, for a breach of contract, and need not resort to a court of equity for an accounting under the general rule that one partner can not sue another at law except for a balance struck and a promise to pay. Likewise, the seller having guaranteed that the earnings of the co-partnership would reach a specified sum, the court holds that guaranty enforceable in an action at law, and without any investigation of the state of accounts between the two as partners. But the purchaser, it holds, must allege compliance on his part with the obligations of the contract, or allege facts excusing such performance. And, the agreement making it incumbent on the purchaser to use his best efforts to promote the interests of the partnership, and the undertaking of the seller to guaranty that the earnings and receipts of the firm were injuriously affected, was competent based in part on compliance on the part of the purchaser with this agreement of his, the court holds that evidence tending to show that the purchaser did not use his best efforts to promote the interests of the partnership, or that he engaged in the transaction of other business, whereby the earnings and receipts of the firm were injuriously affected, was competent to be considered. Moreover, the court holds that the purchaser could not be permitted to testify to conversations which, as he alleged, occurred between himself and the seller prior to the execution of the contract as to the value of the practice of the seller, because all prior statements were merged, as it were, in the writing, and the guaranty incorporated therein became the measure of the liability of the seller with respect to the value of such medical practice. The court also holds that it was not essential to the right of the purchaser to maintain his action for breach of contract that he should affirmatively show that he held a license from the State Board [illegible] Health authorizing him to practice medicine and surgery [illegible] the state, because the relation of physician and patient did [illegible] exist between the parties, and the action was not for the recovery of the fees or the charges of a physician.

Classification of Consumption.—The Michigan statute involved in the case of People vs. Shurly requires that, "whenever any physician shall know that any person whom he is called to visit, or who is brought to him for examination, is infected with smallpox, cholera, diphtheria, scarlet fever, or any other disease dangerous to the public health, he shall give immediate notice thereof to the health officer of the township, city or village in which such person may be; and to the householder, hotel-keeper, keeper of a boarding-house, or tenant within whose house or room the sick person may be," etc. To recover the penalty prescribed for a violation of this provision this action was brought. On the trial it was agreed by counsel for the respective parties that the only question in the case was whether consumption was covered by this provision. The circuit judge ruled, for the purposes of the case, that the statute was not intended to cover consumption, and ruled out testimony offered to show that consumption is a disease dangerous to public health. The Supreme Court of Michigan holds that this was error, reverses the judgment of the lower court, and orders a new trial. The position of the defendant's counsel, as stated in his brief, was that the general clause, "or any other disease dangerous to the public health," was intended to include other diseases of the same degree of infectiousness or danger to life, though not specifically naming them; that the general clause would include yellow fever, leprosy, bubonic plague, and typhus fever. For, he said, it is common knowledge that those diseases partake of the same violent degree of infectiousness as those mentioned in the statute. And the supreme court says that the rule was correctly stated that where a statute, after enumerating specific cases, uses a general term to cover others, the latter are understood to be of the same general character, sort, or kind as those specified. But, while it recognizes this rule, it says that it did not determine this case, for the reason that, if consumption is a disease dangerous to the public health, it is of the same general character, sort, or kind as those specifically enumerated in the sense in which the legislature characterized those diseases, i. e., diseases dangerous to the public health. If there was a distinct dividing line of danger, of which courts might take judicial notice, a different view, it suggests, might be held, but there is, it declares, no such line. The court cannot judicially know what are the varying degrees of infectiousness of different diseases. There is no line which can be drawn other than the line between diseases dangerous to the public health and those which are not. Wherefore, it holds that the question raised in this case of whether consumption is a disease dangerous to the public health was to be determined on evidence, and should have been submitted to the jury. Because this was not done, there must, it holds, be a new trial.

AMERICAN.

3. **Upright Position in Anesthesia.**—French describes a chair-apparatus, in which the patient is fastened during operations, that can be tilted back or set upright as the case may require and illustrates its use by pictures. He speaks especially of its use in operations with ether upon the nose, throat and ear, and sums up its advantages as follows: 1. The very considerable reduction in the amount of blood lost. 2. The reduction of the chances of ear complications, by securing complete drainage of the nasopharynx of blood. 3. The ease, thoroughness and accuracy with which operations can be done in the shortest time, by the retention of the usual relationship between operator and patient.

4. **Asthma.**—In this article, the first portion of which only is included in the present number, Wells describes the theories of asthma that have been held, the vasomotor theory, the uric-acid theory, etc., and toward the close notices certain peculiarities of the disease which seem to indicate that strong mental effects act at least in producing its modifications. He thinks that in theorizing as to its origin we will have to call in psychology and suggests that many of the phenomena are strikingly suggestive of the yet imperfectly understood condition known as hypnotism.

6. **Tuberculosis.**—Knopf describes the methods of infection and their avoidance and notices particularly predisposition, both hereditary and acquired, and maintains that tuberculosis is eminently a curable disease, and that if we can get an abundance of good air and good food, so that it produces new fibrous connective tissue and increases the phagocytic powers of the blood and secretions, the course of the disease will be favorable. So long as the stomach holds out there is hope for the patient and on the general success in this direction depends the cure.

8.—See abstract in The Journal of July 7, p. 52.

9. **Fracture of the Carpus.**—Ross and Wilbert's article illustrates the possibilities of fracture of the carpus from a study of fifty-two cases as shown by radiograms, and questions the rarity of the trouble. They illustrate the different types by diagrams, the scaphoid seems to be the part most often affected. There are two forms of arthritis that are apt to be mistaken for that which follows fracture of the carpus. These are rheumatoid arthritis in which the previous history is of great importance and the X-ray will clear up the diagnosis, and arthritis following prolonged immobilization of the wrist-joint or other injury of the bone above. In fracture of the carpus there is seldom any displacement, and consequently no replacement is necessary. The recognition of the injury is of great importance, however, for the purpose of preventing the consequences that may follow. The wrist must be kept quiet for two or three weeks, then careful massage must be used. This is of special importance in fracture of this part as inducing the absorption of inflammatory exudates.

10. **Tuberculosis in Colorado.**—Bonney asks whether the actual necessities justify the extreme professional stand and the somewhat intolerant popular tendencies that have been shown. He thinks that the percentage of deaths from tuberculosis is a very unfair criterion of the cases developed in Colorado. The occurrence of the disease in the state is by no means evidence that it originated there. He shows from statistics that there has been a very slight increase in the deaths from consumption in Colorado; in fact, there has been a decrease in proportion to the population, notwithstanding the inherited susceptibility of many of the natives. The influx of consumptives into the state has been a matter of some economic importance, and he thinks that compulsory notification and legislation, not meaning personal restriction or isolation, would be an excellent thing. The interference with marriage and the liberty of the consumptive is at present both impracticable and unwarranted. The education of the public as to the hygienic measures and reinforcement of resisting powers will be the proper course to pursue.

12. **Calentura.**—Calentura in the tropics means any kind of fever, but should be limited, according to Foxworthy, to that fever which occurs usually during the months of December, January and February with symptoms of simple, continued fever and a very slight mortality. He describes it as he has noticed it in the Philippines and endeavors to eliminate the possibility of its being malarious. It somewhat resembles dengue, is rarely fatal and is generally of short duration. He says "whether this fever will be recognized as one of the obscure varieties of malarial fever or will be known as a distant relation of influenza which it simulates often in the epidemic forms, or whether it will continue to be one of the many unclassified fevers of the tropics, time and the microscope will decide."

16. **Home Modification of Milk.**—Townsend's conclusions are as follows: 1. The modification of cows' milk, with a knowledge of the percentages, is preferable to guesswork feeding of infants. 2. Percentage feeding can be carried out by a milk laboratory or by home modifications. 3. Milk laboratories are unavailable to many by reason of their absence or on account of the expense. 4. Laboratory modifications do not, in the experience of the writer, agree with infants as often as home modifications. 5. Laboratory modifications are necessarily subjected to more handling and transportations than home modifications. 6. Milk that is fresh, clean, and from cows free from tuberculosis is preferable uncooked, or, in other words, pasteurization and sterilization, although sometimes essential, are to be avoided if possible. 7. The method of home modification and of calculating percentages should and can be made extremely simple, and such modifications are sufficiently accurate and uniform. 8. The addition of cereals to the milk in the form of barley or oatmeal water is generally advisable after the seventh month, and is desirable before that age in some cases as an aid to the digestibility of the milk.

19. **Finger Infection.**—The subject of traumatic infection of the finger is quite thoroughly discussed by Eliot, who points out the pathologic conditions and progress of the infection and speaks of the advantages of the conservative method of treatment. When there is a certainty of stiff-finger, it is a question for the patient to decide whether or not amputation is to be performed. Stiff-finger may be useful if properly treated and placed in a suitable position for work. He reports a number of cases illustrating his views.

20. **Colds.**—Scheppegrell's article treats of the subject of colds commonly so-called, and shows that whatever influence cold has, it is certainly not the most important factor in the production of coryza. Prophylaxis is of first importance; over-heated rooms especially those heated by steam and hot water which do not provide sufficient change of air are to be avoided. The clothing should not be too heavy and warm, and he calls special attention to the fact that excessive clothing induces perspiration which extracts heat, hence the necessity of

removing wraps when entering a warm room. One of the most useful methods of preventing colds is the use of the cold shower bath, which accustoms the system to sudden changes of temperature. Another important point is keeping the nasal passages in a normal condition. As regards the constitutional treatment there is hardly any subject on which there are so many fallacies, among these the use of quinin, which he thinks has really very little effect. Very few internal constitutional remedies are of much use; a brisk saline purgative if taken within the first twenty-four hours is one of the most useful remedies and the most available for all cases. He speaks also against the local use of drugs, particularly cocain, which is often inducive of habit. The simplest and most beneficial treatment is to bathe the nostrils with a warm normal salt solution, which soothes the mucous membrane, washes it free of acrid secretions and is absolutely uninjurious. It should be used gently with only sufficient pressure to allow it to pass through the nostrils. With the ordinary precautions he has never seen any ear trouble produced by its use.

21. **Rheumatism and Indigestion.**—Page reports a case in which he has treated rheumatism with piperazin water, a combination of phenocoll and piperazin, with strikingly good effects. He has also employed it in cases of chronic dyspepsia, with little modification of diet and with very remarkable beneficial effects.

22. **Medullary Narcosis.**—Marcus gives the history of this method, which is now coming into favor, giving due credit to Corning and attributing to Bier its introduction into surgery and to Tuffier the perfection of its technique. It was first used in obstetrics by Kreis, and he credits to Marx the first extensive report and application of the method in obstetrics in this country.

23. **Tuberculosis.**—Tuberculosis is a disease occurring from crowded, unsanitary, uncleanly, malnutritious and generally bad hygienic surroundings. The bacillus, according to Brooks, is only the histologic exponent, not the whole of tubercle, much less the disease. Pure local tuberculosis is afebrile; it is only the mixed infections that produce fever, the streptococcus being chiefly to blame. As regards treatment it is evident, he says, quoting Brieger, that a specific serum can not meet the indications furnished by mixed infection. It has been noted that the leucocytes and their alexins play a lesser part in this infection than in any other disease. As for drugs, the much vaunted creosotes and guaiacol are inefficacious, climate also is non-essential. Successful treatment resolves itself into the rational application, conversely, of its rundamental causative factors, the diametric antithesis of its so-called predisposing etiology, plus, to use the words of Moeller, "the summation of many minor curative measures, each of which, perhaps, if taken by itself, has a slight effect but collectively are productive of the greatest good." These are supplied by sanatorium treatment, and he maintains that inhalation of antiseptic or medicated atmosphere during the night's rest, hydrotherapy, diet, systematic treatment and, more than anything else, the competency and sincerity of the physician in charge are the essentials of success. In conclusion he says success of treatment is connected with early recognition of the disease, and that it may be diagnosed even without bacteriologic examination is held by high authorities. Treatment must be commenced early.

24. **Hernia.**—The points emphasized by Haynes, whose paper is illustrated by figures in sections, are: 1. We should know the construction of the normal inguinal and femoral regions. 2. We should know the changes which take place when a hernia has occurred at either of these regions. 3. In attempting a radical cure we should seek to reproduce the natural construction of the parts. 4. Nothing but absorbable suture materials should be used. 5. Every precaution for obtaining primary union should be utilized and carefully followed. 6. A truss should be applied to preserve the effects of the operation. If a radical cure has been done a truss is unnecessary; if it has not been done, a truss will not prevent the return of hernia.

25. **Light as a Remedial Agent.**—Kime gives illustrations of his method of photographing through the human body with examples of his success and gives as the principles on which the therapeutics of light is based: 1. The germicidal action due to the violet end of the spectrum. 2. The irritant action of the chemical rays. 3. The power of light to penetrate the tissues of the body. 4. The chemical action of light on the blood itself while circulating through the parts bathed in the powerful light. He remarks that he has treated a number of cases of tuberculosis of the lungs with the light treatment as shown in his first illustration of photographing through the human body, and he reports several cases of cutaneous tuberculosis successfully treated.

26. See also ¶28.

28. **Inebriety.**—Crothers remarks in regard to the gold cure that its day has passed, and analyzes some of the statistics of its results, finding that after ten years no more than 2 to 4 per cent. of the cases "cured" have continued temperate. This compares closely with the results of temperance revivals. In contrast, he points out how scientific treatment has furnished a much larger percentage of success. The chief causes of inebriety are noticed. He emphasizes the fact of the possible self-limitation of inebriety and discusses its relation to various diseased conditions, the policy of the sudden withdrawal of alcohol, the drug treatment, etc. The main point of his paper is the importance of the medical rather than the moral treatment of habitual drunkenness. See also ¶26.

37.—See abstract in The Journal of September 29, p. 841.

38. **Formaldehyde in Milk.**—This paper appears to be the result of a series of questions sent out to the secretaries of state boards of health and departments of health in the United States. In only one case was the answer returned favorable to the use of formaldehyde, and Dr. Young's views, aside from the findings of experimental work and clinical observation, lead him to advocate that it should be prohibited. He says that: 1. It is the question of encouraging or abetting the addition of a potent chemical to a food-supply by ignorant and slovenly individuals. 2. The absence of legal prohibition will enable slovenly and dishonest persons to put dirty and unwholesome milk upon the market. 3. There is no real advantage in using chemical preservatives in milk, if we are careful and cleanly. 4. The fact that one man or a few take antisepticized milk without apparent harm does not warrant the deduction that babies may be frequently doctored with it. 5. In former years, boric and salicylic acid have been deemed innocuous, but it has been found since that they both have bad effects if taken continuously. One of the correspondents, while not advocating formaldehyde seemed to think that it evaporated quickly. This, however, is a mistake according to the experience of those that have had much to do with it. Another correspondent suggested that it might be allowed under a law establishing a legal maximum. Dr. Young thinks that this would be equivalent to a complete surrender to the adulterators. The results of his examination of all the available printed and other reports regarding the action of formaldehyde seem to justify and require the following conclusions: That, used as a preservative, it tends at least to impair the nutritive value of milk; that its tendency is also to interfere with the digestive processes—in either case it is only a question of dosage, and the limit of safety is difficult to determine; that, though the inhalation of formaldehyde gas is much less dangerous than the breathing of the other gaseous agents much used as disinfectants, the results of tests upon animals and one case of accidental poisoning of a human being, indicate that formaldehyde taken into the digestive system may produce dangerous and even fatal results; that it would be unwise and unsafe to encourage or to suffer the use of formaldehyde in the public milk-supply, even under any possible restrictive regulations; that in every state, as there are now in many, there should be a law prohibiting with effective penalties the use in milk of any chemical preservative whatsoever. These, at present, are the only rational and safe conclusions. If new light arises in the future we can take our bearings anew, and correct our course if need be.

41.—See abstract in THE JOURNAL, xxxiv, p. 1333.

42.—Ibid.

45. **Treatment of Hysteria and Neurasthenia.**—Loveland divides the special points which he makes in regard to the treatment of this condition into five heads. 1. Correct errors of physique. In many cases of both neurasthenia and hysteria we find a debilitated general condition. We should look for evidences of lithemia, malaria, syphilis, etc. Any disease affecting the nutrition, or any irritation producing nerve-waste should be corrected. The means to be employed may vary. The free use of water should be enjoined and the diet regulated so as to be unstimulating and wholesome. 2. The surroundings should be looked after; if they are depressing, they should be changed. Exclude everything that is not cheerful, induce exercise and avoid if possible the wheelchair and hammock habit or anything that will tend to inactivity. 3. Hydrotherapeutics and calisthenics are powerful agents for good; he mentions the methods and includes in this treatment massage. The mental attitude of the patient must also be attended to. The moral treatment is especially important; it is the secret of the success of faith cures, "Christian Scientists," etc. He would not throw aside medicine. Even a more thorough examination than the physician might think necessary will have a good effect in increasing the confidence of the patient. The medicines that are mentioned are often overrated. Strychnin comes first as a nerve tonic, but it should not be used so that it will be felt by the patient. Mild, harmless sedatives like valerian, camphor and hyoscyamus, judiciously used are also serviceable. Laxatives may be needed, in which case phosphate of soda is one of the best. Other medicines may suggest themselves. The latter part of the paper is taken up with reports of cases.

46. **Graves' Disease.**—Norbury describes the symptoms of Graves' disease, of which those referable to the heart are the most characteristic, and discusses the theories. So far as clinical facts go, he believes the theory that the disease is one of the cervical sympathetic nerves and that it is the result of the irritation of the vasomotor dilator nerves and of those nerves of the head and heart that have their origin in the medulla. He is convinced as to the nervous origin of the disease.

48. **Longevity of the Literary Female.**—The first paper of Spitzka's reviews a number of curious facts in regard to literary women, especially that their marriage relations are more unfortunate than the average. Of 60 literary women, several married twice and a few three times, so that there were 77 unions represented. Of these, 22 became dissolved by separation or divorce—by apparently a typographic error it is said that 57 husbands were survived by four widows. Of 382 cases of female poets, scientists and journalists, 280 were found to be married and to have sufficient data existing relative to them to be useful for the present inquiry. Of these 61 married twice, 3 a third time, and one a fourth time, making a total of 345 husbands to 280 wives. Of this number 230 were not divorced from their first husbands, and of the latter 175 survived their partners. He found that the ratio of surviving widows to surviving husbands, among these literary women is that of 100 to 26; the ordinary ratio of widows to widowers being about 2 to 1. This shows an immense discrepancy against the husbands of literary women. If to make a fair proportion he had allowed those who had been divorced from their second husbands to remain in the columns of the surviving, the ratio would have been only 100 to 21. The statistics direct attention to the fact that marriages between literary females and non-literary males contrast unfavorably with those where both members are literary, and that this exhibits itself in the earlier mortality of the male partner, and that the literary female is less adequate to the duties of a wife and mother than the average woman. As regards divorce, he finds that 75 out of 290 with accessible records have been divorced or otherwise separated from husbands, and that so large a proportion of these repeated this performance, that no less than 82 husbands figured in divorces from 75 wives.

56. **Prenatal Degeneracy of the Eye.**—Dean first remarks on the general conditions of degeneracy and reports cases in which he has found ocular symptoms indicating this tendency. Of these, retinitis pigmentosa seems to be the most frequent, is also accompanied with other stigmata, often hereditary, and is very frequently associated with consanguinity of parents. The other forms which he mentions particularly are the presence of persistent hyaloid accompanied with congenital absence of Mueller's muscle, and congenital glaucoma, both of these being examples of persistent fetal conditions associated with degenerative taints. Coloboma and aniridia were also found in several cases with bad family histories.

59. **Etiology of Malignant Diseases of the Skin.**—The etiology of carcinoma is reviewed by Hartzell, who concludes that we can regard it as fairly well demonstrated that it results from some profound and more or less permanent alteration of the mechanism of cell division. The alteration may in his opinion result from long-continued irritation of a mechanical or chemical kind, including under the latter the microorganic toxins. The immediate causes of cancer, therefore, are probably multiple. Xeroderma pigmentosum is obscure as to its causation, but he holds that, owing to the early age at which it appears and the frequency of its occurrence in members of the same family, there is an inborn skin defect. He suggests also, in view of the rapidity of growth and malignancy of melanotic growths, that it is quite possible that the pigment exercises some toxic effect on the epithelium, producing a profound disturbance in the processes of the cell division. As regards Paget's disease, age and sex are the two most important etiologic factors; it is rarely found in men and before the age of 40. Of the direct causes we know nothing. The psorospermial theory of Darier has been thrown out as unfounded, and Hartzell thinks that it is likely that the irritation and injury to the nipple during nursing plays some part in the production of the diseased condition of the epidermis producing the cancerous affection.

60. **Recurrent Epididymitis.**—After a review of the subject and brief reports of a number of cases Chetwood concludes as follows: 1. Surgical resection of the testicular ducts, which obliterates the lumen entirely and positively prevents an ascension of the spermatozoa into the urethra, also prohibits the descent of inflammation from the urethra into the epididymis. 2. The pathologic occlusion of the ducts by inflammatory process only accomplishes this result partially, since it is clearly in evidence that many of the cases having had double inflammatory epididymitis still continue to suffer from a recurrence of inflammatory attacks in the epididymis, and since it is also proved that some of these individuals continue to have vital spermatozoa in their seminal discharges and to retain the capacity to impregnate their wives. He is not aware that this point has been clearly demonstrated before this writing.

61. **Treatment of Malignant Diseases of the Skin.**—Cancer being a local disease, its treatment must necessarily be local, and constitutional measures other than those needed to support the patient are useless. Of the local treatment there are two methods; caustic and excision. The former, while it has its advocates, has a weak point in that it postpones the removal of the lymphatic tissues and glands in the neighborhood. Shepherd holds that there may be affection of the glands without apparent symptoms, and that in all cases, to be on the safe side, all the neighboring glands and lymphatic tissue should be excised, especially when the disease occurs in such parts as the tongue, lips and genital organs. The results of excision, so excellent of late years, have been due to the recognition of the facts that cancer is a local disease and therefore must be removed early, and that it spreads by the lymphatics. He admits that there are certain malignant ulcers of the skin which, if seen early, may be successfully removed by caustics, especially those slow-growing forms seen in regions somewhat removed from the glands, such as in the nose, forehead, cheeks, temples, etc. In rodent ulcer, in cases of slow growth and when the glands are not rapidly affected and where the ulceration

is superficial, other means than excision may be employed. Caustics are also most useful when the disease has affected the bone. He has grounds to think that there is a medium to be found between the practice of physicians and that of surgeons in the treatment of this condition. If caustics were properly applied instead of being used only by quacks, many patients would be better off than is now the case. The use of toxins obtained from cancerous growths, advocated by Adamkiewicz in 1893, has been practically discarded. The erysipelas toxins of Coley have been rather more successful. The different caustics such as arsenic, caustic potash, and their action are here mentioned, as is also electrolysis, advocated by Dr. G. B. Massey. In skin sarcoma, when single and localized, early and complete excision is the best treatment. In cases of malignant multiple sarcoma, hypodermic injections of arsenic have been successful in many cases and attacks of erysipelas have actually caused sarcoma to disappear, hence the suggestion of Coley, who has reported success. Shepherd has himself tested these toxins but without good results.

62. **Proliferation and Phagocytosis.**—Mallory first describes the different phagocytic actions observed from various infections, and in conclusion suggests the question whether the processes he has described are due directly to the action of toxins or reparative. In repair, cells proliferate for definite purposes—to cover denuded surfaces; to replace loss of tissue; form new blood-vessels, etc. The cells, however, which proliferate under the direct action of toxins, multiply greatly in excess of need and show lack of definite purpose. They may exert some more or less beneficent action, possibly produce antitoxins, but they must not be regarded as reparative and may do great harm, block up lymphatics, produce narcosis, be carried to the liver as emboli and otherwise interfere with the organic economy. The phagocytic cells are phagocytic beyond all bounds of necessity and destroy great numbers of active, useful cells. They are all abnormal and, to a certain degree, malignant.

64. **Neurofibrils of the Ganglion Cells.**—Paton has studied the special neurofibril structure of the cortical ganglion cells, using a special modification of his own of Apathy's method. He hopes still further to improve this method in future research. As regards the nature of neurofibrils, he disputes their being artefacts, showing that they undergo rapid degeneration after death. In one of his sections the visible network of fibrils is not within, but is superimposed upon, the cell and its processes, and he thinks this extracellular network is that which Held has described as the pericellular network of terminal axones, also the reticulum surrounding the nerve cell described by Golgi. After a careful study of the development of the ganglion cell, he has come to the conclusion that the presence or absence of "gemmules" is dependent upon the existence or non-existence of fibrils. A gemmule is formed by a silver deposit at the point where the nerve filament or fibril enters the nerve process. This is also found if the fibril is simply lying on the process. They are found either at the point of entrance or at a simple contact of the fibril with the protoplasm of the cell process.

65. **Oxaluria.**—The conclusions of Baldwin's experimental study are as follows: 1. As varying amounts of calcium oxalate may be held in solution in the urine, conclusions based on the presence or number of calcium oxalate crystals found therein are of no real value as an indication of the quantity of the oxalic acid present. 2. Unless the utmost care is exercised, the results obtained by quantitative estimation of oxalic acid are subject to large percentages of error. This is especially true in the use of Neubauer's or Shultzen's methods, in which the calcium oxalate is precipitated in an alkaline solution. 3. An ordinary mixed diet regularly contains traces of oxalic acid or its salts. 4. A portion of the oxalic acid ingested with the food may be absorbed and reappear unchanged in the urine. 5. The normal daily excretion of oxalic acid in the urine fluctuates with the amount taken in the food, and varies from a few milligrams to two or three centigrams, being usually below ten milligrams. 6. In health, no oxalic acid, or only a trace, is formed in the body, but that present in the urine has been ingested with the food. 7. In certain clinical disturbances which in some of the cases studied above were associated with absence of free hydrochloric acid from the gastric juice, oxalic acid is formed in the organism. 8. This formation in the organism is connected with fermentative activity in the alimentary canal. *a.* Prolonged feeding of dogs with excessive quantities of glucose, together with meat, leads eventually to a state of oxaluria. *b.* This experimental oxaluria is associated with a mucous gastritis, and with absence of free hydrochloric acid in the gastric contents. *c.* Oxaluria and accompanying gastritis are referable to fermentation induced by the excessive feeding with sugar. *d.* Experimental gastritis from fermentation is associated with the formation of oxalic acid in the gastric contents. 9. The symptoms attributed to an oxalic acid diathesis, with the exception of those due to local irritation in the genito-urinary tract, do not appear to be due to the presence in the system of soluble oxalates, but are more likely to depend on other products of fermentation and putrefaction.

66. **Serum-Globulins and Antitoxin.**—From a series of experiments Hiss and Atkinson conclude that the amount of antitoxin substance obtained by precipitation with magnesium sulphate from the blood-serum of the horse, corresponds as nearly as can be determined in full to the protective power of the serum from which it is obtained. Equal amounts of precipitate by magnesium sulphate from immunized and non-immunized horses act differently toward toxin, thus the proportion of protective substance to the precipitate from non-immunized serum is exceedingly small as compared with the proportion of antitoxin from the precipitate from the serum of immunized horses. The average precipitate from the latter is more abundant than that from the serum of non-immunized horses, and before immunization the serum gives less abundant precipitates than afterward. The proportion of increase per unit of antitoxic strength for the same or different horses is not constant. This may be due to the increase of inactive substance or to imperfect methods of determination. They do not feel warranted in considering any parts of these precipitates as anything else than globulin, but do feel warranted to conclude from the fact that globulins of normal serum do not protect or only in comparatively large amounts, against diphtheric toxin, that new globulins are formed, or rather greatly increased in the serum of immunized horses and that these globulins protect against the toxin. Every animal has its physiologic and pathologic history, hence absolute conformity in the results obtained is not expected.

67. **Antitoxic Strength of Globulins.**—Atkinson has carried out some investigations as to the fractional precipitation of globulin and albumin of normal horses and diphtheric antitoxic serum and the antitoxin strength of the precipitates, from which he deduces the following: 1. The globulins of both normal and diphtheria antitoxic serum exhibit chemically toward reagents the same reactions, being precipitated by magnesium sulphate and split up into fractions in precisely the same way. 2. All the diphtheric antitoxic power of both normal and immunized serum is always carried by the globulin and its fractional precipitates. 3. During the fractional precipitation of the serum-globulin of horses immunized from diphtheria toxin and horses not immunized from diphtheria toxin, some of the globulin is lost, likewise at the same time some of the antitoxic power of the globulin of the immunized serum is lost. 4. These reactions, considered in connection with the fact that different observers as well as the author have found diphtheric antitoxic power in normal horse's serum and that this antitoxin separates with the globulin, strongly inclines him to consider "diphtheria antitoxin" a form of globulin. 5. The reactions of globulin, previously separated from the serum by magnesium sulphate, with sodium chlorid lead one to think that there is a formation of globulin salts. 6. Since serum albumin in a magnesium sulphate solution gives fractional precipitates at definite temperatures, it seems not improbable that the albumin is precipitated in the form of albumin salts.

68. **Sporothrix Schenckii.**—Hektoen and Perkins describe a case of refractory subcutaneous abscess similar to those noticed by Schenck in an article in the *Bulletin of the Johns Hopkins Hospital* for December, 1898. Dr. Hektoen was unable to see any distinguishing difference either culturally or morphologically between the fungi of Dr. Schenck and those of their own observation. A characteristic clinical feature in the human cases that have been found is the refractory character of the subcutaneous abscesses.

78. This article will be noticed editorially.

79. **Echinococcus of the Pleura.**—Cary and Lyon describe a case which they consider of interest from its rarity and from the peculiar type of degeneration of the cyst wall which, according to them, is described here for the first time. The wall became a thin, hyaline structure which was derived by the process of degeneration from the cuticular walls of the parasite itself and not from the tissues of the host.

83. **Pedicle Flaps in Injuries of the Hand.**—Schroeder describes the method of restricting contracted cicatrices of the hand by the pedicled-flap method and illustrated by cases. For covering the thumb, dorsum or palm, flaps may be taken from the chest or abdomen; where the palmar surface of fingers is destroyed it is much better to have double pedicles and they can be best obtained from the hip. The advantages are: 1, mobilization; 2, elasticity; 3, certainty of taking.

84. **Hydrocephalus.**—After reporting a case of internal hydrocephalus following cerebrospinal meningitis, Joslin gives a résumé of the literature of such cases, description of the pathologic symptoms, prognosis and treatment of the condition. He notes especially the very long duration and the large mortality, though it would appear that the prognosis is better than has been supposed. As regards treatment he sees little benefit from tapping.

90. **Obstetric Surgery of Pelvic Contraction.**—It is generally believed that pelvic contractions or deformed pelves are more common among Europeans than among Americans. While Jewett seems to doubt the absolute truth of this, he admits that it is much less common, though not as rare as usually assumed. There is a lack of statistics of pelvimetry in this country which has been noticed by European authors, and he gives here the simplest methods of measurements. External mensuration has the advantage of being least uncomfortable to the patient and most easily done. The only external diameter essential for the purpose is the external conjugate, and this is best measured, not from the spine of the last lumbar vertebra, but from the depression immediately below it to a point on the pubic surface a little below the upper margin of the symphysis. With the external conjugate at or below 6 or 6¼ inches, the pelvis is invariably contracted. With one at or above 8 inches it is almost surely ample. Between these two figures the matter is in doubt and should be determined by other measurements. Of the internal measurements the diagonal conjugate is the most important and it should not be less than 4½ inches. Allowance may be made for the variations in depth, thickness and inclination of the symphysis, but these are less important in diagnosis of deformity than in determining its degree. Some usual indications of pelvic contractions at labor are: 1. Failure of the head to engage during active labor. 2. Failure to engage by well-directed suprapubic pressure. This often may be employed to advantage as a test in a few weeks immediately preceding labor. 3. Failure of tentative traction with forceps. In partial enlargement of the head the latter should always be tried with the aid of the Walcher posture before resorting to surgery. He speaks favorably of symphysiotomy, believes that it still holds an important place in obstetric practice and does not believe that it leaves any permanent enlargement of the pelvis. It is of value in cases of slight contraction and is simpler than Cesarean section. Considering Cesarean section he remarks that the disposition of the uterus is important, but the ethical side of the question must be considered; except when demanded in the interest of life, the surgeon can not assume the right to remove it without the patient's consent.

95. **Hemolysins.**—Fisch notices the results of Ehrlich and Morgenroth, who find that hemolysins which will act on other animals and other individuals of the same species will not act on individuals producing them. The autolysin seems to be undiscovered. He reports his own experiments, which bring out nothing special other than that found by Ehrlich and Morgenroth, and says that it seems most probable to explain the phenomena by the absolute absence of receptors in the tissues of an animal for the haptophorous groups of its own corpuscles.

103. **Common Food Adulterations.**—In this second article, Leuf notes the adulteration of extracts, vanilla for example, which is very largely made up of tonka bean and others of various fruits are manufactured of compound ether, coloring matter, sugar or glucose, and water. Both the natural and artificial extracts usually contain preservatives, the commonest of these being salicylic acid. Lemonades are manufactured from oil of turpentin and tartaric acid with sugar. Milk and cream are adulterated with water and preservatives. Canned goods are usually pure. The only adulterant of coffee is chicory, and this is only possible when it has been ground. The public is very often imposed upon by getting a poorer grade than it pays for, but it always gets coffee if it buys the bean, and does its own grinding. Very little good tea comes to this country. It is a common belief that vinegar is merely dilute sulphuric acid, but its production is so cheap that it would not pay to adulterate it. Vinegar may be diluted, and a so-called vinegar essence is sold consisting simply of concentrated acetic acid or crude pyroligneous acid. Cocoa and chocolate are deteriorated by the abstraction of the fat before being ground and are also diluted with varying proportions of cereal starches and ground cocoa shells. The adulteration of wines, beer, etc., is also noticed.

114.—See abstract in The Journal, xxxiv, p. 1418.

116. **Surgical Treatment of Ulcerations of the Stomach.**—Wenner reports two cases of gastric ulceration treated by operation, and from a study of these and of others gathered from the literature of the past years he considers the following conclusions justified: 1. That the severity of the hemorrhage does not indicate the degree of ulceration. 2. That the time of vomiting bears no constant relation to the location of the ulcer. 3. That repeated small hemorrhages or recurrence of a second grave hemorrhage demand operation. 4. That after careful medical treatment extending over a period of two months, without amelioration of symptoms, an operation should be advised.

117.—See abstract in The Journal, xxxiv, p. 1624.

135. **Organotherapy in Gynecology.**—Jack reports several cases in which organotherapy was employed, and concludes: 1. Thyroid extract is one of our most reliable vasomotor constrictors. In gynecology it should be limited to hemorrhages, especially those in which epithelial elements of the endometrium are concerned. 2. Mammary extract controls the hemorrhages from fibromata and reduces the size of the tumor; in some cases causes their disappearance and in such disorders it should be preferred to thyroid extract. 3. Parotid extract is the best remedy yet brought out in the treatment of dysmenorrheal; it softens pelvic exudates, regulates menstruation, and relieves nervous symptoms. 4. Ovarian extract is indicated in nervous symptoms of the menopause or when from any reason it is desirable to increase the flow. He believes in its function of internal secretion and thinks it the best ovarian stimulant.

FOREIGN.

The Lancet, October 6.

Aneurysm of the Renal Artery. Henry Morris.—Two varieties of aneurysm of the renal artery are known after injuries: 1. Small sacciform aneurysm, the walls of which are formed by some or all the coats of the artery. 2. Large, false aneurysm, the walls of which are composed of the condensed fibrous tissue developed around the extravasated and coagulated blood, and with which the surrounding organs and tissues become more or less firmly matted. False aneurysm sometimes reaches an enormous size and may be due to the giving way of the small true aneurysm, to the yielding of a thrombus, which temporarily closed a ruptured artery, and to immediate outpouring of blood from a ruptured artery. True aneurysm may also be associated with an extravasation of blood and also with the false aneurysm and both may be the result of some accident. Morris gives accounts of cases of various types of this accident and discusses the etiology. Of 19 cases 12 were traumatic and 7 spontaneous. Of the 12, 2 were sacciform, 9 false and 1 doubtful. Males appear to be particularly susceptible as 10 out of the 12 were of that sex. The spontaneous cases were associated with malignant endocarditis with multiple embolism, cancerous degeneration of the arterial coats, nephritis, and probably embolism and thrombosis. Small sacciform aneurysms when unruptured produce no distinct changes in the kidney. False aneurysm is associated with pressure changes and numerous symptoms, tumor, hematuria, etc. As regards the diagnosis the small sacciform aneurysm giving rise to any symptoms may be unrecognized during life. The tumor caused by false aneurysm is especially difficult to diagnose and may be confused with renal new growths, hydro or hematonephrosis, etc. Its prognosis is most unfavorable. The only rational treatment is nephrectomy and the removal of the whole or greater parts of the aneurysmal swelling. The operation will generally have to be commenced as an exploratory one, and when the tumor is recognized the incision should be enlarged, the pedicle secured or renal artery ligated, at any rate before attempting to amputate or remove the sac. The risks are hemorrhage and shock. In exposing the sac it is advisable to incise it and remove a little of its solid contents. If hemorrhage occurs the opening should be immediately packed with gauze. The adhesions may unite the wall of the aneurysm with the peritoneum and bowel, and if the adhesions are tough and firm it may be impossible to remove the whole of the sac wall. As much of the wall as possible should be removed and the rest left and drained.

British Medical Journal, October 6.

Some Problems of Tropical Medicine. William MacGregor.—In this address on tropical medicine MacGregor gives some interesting particulars as to the introduction of old diseases among the tropical race as well as regards the special indigenous diseases themselves. Typhoid fever, for example, was unknown in Polynesia, and also in British New Guinea until introduced. The disease of yaws, however, is one that almost everyone in the tropics will come in contact with, and is considered by the natives as inevitable. While not very contagious to Europeans it is loathsome and troublesome when caught. It is much more mild in the African and Papuan than the Polynesian, and MacGregor generally found it not very readily curable; as regards its eradication, situated as he was in New Guinea, he thinks he might as well have tried to arrest an earthquake. Venereal disease was unknown to the Pacific Islanders until introduced and seems to take a specially active course among them. The same is true of measles, which destroyed about one-third of the Fijians when first introduced, giving a remarkable example of the exuberance of a new disease among a new people. It was not more surprising in Fiji, however than the itch in New Guinea. This malady, introduced in some old clothes, spread like a tidal wave, affecting thousands of the population; but after a while it finally declined to a level, at which it will probably always keep in a community where clothes are common property and itch attacks the human face. Dysentery was unknown in British New Guinea and Fiji before the advent of Europeans, and its mortality has been exceedingly high in the Polynesian Islands. The man who will work out an effective means of dealing with it will be the greatest benefactor of the tropical [illegible] is the most important matter to both the stu[illegible] diseases and the tropical resident. Since the d[illegible] mosquito's agency we will have to take me[illegible] neglected; mosquito nets, protection of pools [illegible] from insects and avoidance of exposure through the means of clothing, etc., drainage and many other matters are suggested. In the tropics the population going half-naked complicates the situation. Civilized Europeans will not wear low-necked dresses in malarial regions if they have learned to take proper care of themselves, nor will they sit with their feet under the table with their ankles exposed, excepting for silk stockings. Elephantiasis is another mosquito-borne disease, and though of minor importance, is an interesting subject. Diphtheria, cancer, and tetanus appear to be all introduced diseases in New Guinea and the Polynesian Islands. Erysipelas was also unknown there. Tinea imbricata is a very evident disorder. Ankylostomiasis is indigenous in the Pacific without doubt. The exclusion thus far of rabies from the Australasian colonies is a most important matter, and with the habits of the wild and domestic native dogs its introduction would be a very serious one. The government measures for excluding this disease are, it is hoped, taken effectually for all time. Other subjects mentioned are the jigger, which is comparatively unimportant; leprosy; quarantine, which is not an English favored method, and the need of medical men being experts on the question of drinking-water especially.

A Discussion on Subdiaphragmatic Abscess.—The discussion is opened by Godlee, who first notices the anatomy of the subject, and then passes on the classification as proposed by Maydl. When an ulcer of the stomach bursts in the general cavity the subdiaphragmatic portion of the collection of fluid must not be regarded as a separate abscess, but occasionally the effusion is localized, and then we have essentially an acute sub-diaphragmatic abscess. It is generally limited to the right by the falciform ligament of the liver, its other limitations will vary with different cases. Occasionally the rupture occurs on the posterior aspect of the stomach, giving rise to a collection in the small sac of the peritoneum and this may also be called a subdiaphragmatic abscess. The abscesses resulting from gradual rupture of an ulcer where adhesions are previously formed, are very different, and may set up processes in various directions. They may also be accompanied with collections of serous fluid in the pleura. Rupture of an ulcer of the duodenum or transverse colon may cause subdiaphragmatic pneumothorax, a collection of pus and gas pushing the diaphragm up sometimes quite high and reaching down a long way into the abdomen. A simple opening of the abscess may effect a cure, but occasionally it may be possible to reach and close the perforation. Those resulting from appendicitis often track up along the ascending colon and cause a collection between the liver and diaphragm. General peritonitis is not infrequently associated with the formation of pus around the liver and spleen. Suppurating hydatids of liver and spleen may lead to enormous collections of pus beneath the diaphragm, which may be mistaken for empyema, and many abscesses of the liver erupt into the subdiaphragmatic space. Acute suppuration of the gall-bladder may also be accompanied by subdiaphragmatic abscess, though more frequently it is situated farther down. Perirenal abscesses, while they usually point in the loin, may be purely subphrenic. They are not like those hitherto considered, peritoneal, but separate the peritoneum from the diaphragm. They are generally associated, however, with a certain amount of plastic peritonitis with its usual symptoms. The diagnosis is somewhat obscure, though the treatment is not difficult when once diagnosed as a rule. Cases are recorded of abscess in this situation following injuries unaccompanied by wounds. Godlee thinks that these depend on the rupture of some previously existing ulcer. That cases may occur after wounds is generally understood. Metastatic abscess is mentioned, but he does not understand just what is referred to, and has no personal experience with such. Caries and necrosis of [illegible] *rise to subphrenic abscess,* [illegible] hardly [illegible] use [illegible] is [illegible] way down to the space below the diaphragm, but this is much less common than for a collection of matter below to work upward. Actinomycosis so frequently affects the liver that it almost deserves a special heading, but its progress is so slow, however that there is always time for adhesion to occur before the suppuration extends beyond the capsule of this region. Two other possible causes are mentioned, tuberculous peritonitis and diseases of the pancreas, including calculi and pancreatitis.

A Discussion on the Methods at Present Available for the Treatment of Simple (Subcutaneous) Fractures. William H. Bennett.—Bennett sums up his conclusions in regard to the treatment of simple fractures in the following statements: 1. The treatment of simple fractures at present, although less stereotyped than hitherto, is still conducted generally too much on lines which are traditional rather than rational. 2. The use of splints for long periods is disadvantageous, especially in the form of irremovable appliances such as plaster of paris and the like. 3. Speaking generally, the earlier movements of the joints above and below the fracture in a long bone are used the shorter is the time occupied in recovery. 4. The legitimate scope of the operative treatment of simple fracture is limited, and should be confined to cases which are otherwise unmanageable; special cases such, for example, as certain spiral and oblique fractures, mainly of the tibia, and certain fractures near joints, notably of the humerus at the elbow. 5. The operative treatment of recent fracture of the patella is by no means so generally satisfactory or so free from risk as published cases would tend to show; and further, in cases in which the separation of the fragments does not exceed half or even three-quarters of an inch, as good results for practical purposes are obtainable without operation although less rapidly. 6. The use of massage and passive movements immediately in simple fracture when the circumstances of the patient and of the practitioner admit of it either in its entirety or with modifications is, in the majority of cases, the best means of effecting a rapid and useful recovery. 7. The tendency of late has been to exaggerate the degree of disability and diminution in wage-earning capacity following upon simple fractures. 8. Although no pains should be spared in obtaining perfect apposition of the fracture ends, moderate displacement, provided that it is not rotatory, is not necessarily followed by any disability if care be taken by the use of early movements to prevent any matting of the parts around the fracture; in other words, the disability which follows in certain cases in which the position of the united fragments is not ideal is due, not to the bony deformity, but to the adhesion of the soft parts around, which is easily preventable. 9. Having regard to the unavoidable modifications which must be dictated by the circumstances, social and otherwise, of the patient, and by the facilities possessed by the practitioner, no one method of treatment for simple fractures can be insisted upon for routine use even in cases in which the local conditions are precisely alike. To the discussion of the methods in regard to simple fracture he adds in tabulated form the information obtained from submitting a series of questions to 300 physicians of London and other parts of Great Britain.

Annales de la Soc. Med.-Chir. de Liege, July.

Granulation Through Gauze. Roersch.—The gauze applied in dressing a large burn on a child was left when the dressing was renewed. Granulation was so intense that the tissue proliferated through the gauze and a layer of granulations formed on the external surface. They became painful and suppurated; the gauze rotted and the entire surface of the wound had to be scraped, after removal of the large flap of gauze with granulations still adherent on both sides.

Presse Medicale (Paris), September 22, 29, October 6.

Epididymo-Testicular Tuberculosis and Ligature of the Spermatic Cord. P. Mauclaire.—Suppuration and a prostatic lesion are the signs of tuberculous epididymitis. The absence of a discharge excludes gonorrhea, and syphilitic infection is usually localized on the testis, which becomes flattened and completely insensible even to strong pressure. Mauclaire treats epididymo-testicular tuberculosis by ligating the spermatic cord in two places, 2 cm. apart, close to the inguinal canal, and severing the cord between them. The testis soon establishes collateral circulation by adhesions with the neighboring parts. The advantages of this method are manifold. It retains a "moral" testis, separates a tuberculous focus from the rest of the organism, isolates it from the prostate and is possibly able to prevent infection of the other testis, which is not always accomplished by castration. His results have been extremely encouraging. The testis may swell at first but by the end of a month atrophy commences, or it may retain its normal size for six months, but sooner or later it becomes transformed into a painless bunch. He sutures the wound completely after cauterizing.

September 20.

Simple Primary Hyperchlorhydria. L. Sansoni.—Fourteen years' experience as a specialist in gastric troubles has only confirmed Sansoni's previous conviction that what we call hyperchlorhydria is in reality merely an exaggerated specific sensitiveness of the gastric mucosa to the hydrochloric acid, which is not necessarily in excess. His chief arguments in favor of this view are that perfectly healthy persons may have an exaggerated gastric secretion or hyperchlorhydria without disturbances, and that this exaggerated secretion may persist or even increase after complete recovery from what we call classic primary hyperchlorhydria. Also the existence of a normal or subnormal gastric secretion in persons exhibiting all the symptoms of primary hyperchlorhydria, and the efficacy of the usual means of cure in such cases. He therefore proposes for the affection the more accurate and descriptive term "digestive hydrochloric hyperesthesia." He adds that it is impossible to determine the exact figure representing the normal hydrochloric secretion of the stomach, and that the alterations in this secretion are unable, alone, to originate morbid phenomena. The specific hyperesthesia of the gastric mucosa for hydrochloric acid is also liable to cause a reflex spasm of the pylorus and hence retention of the food and, secondarily to this retention, a continuous secretion of gastric juice. These phenomena are proved by the abolition of the spasm and evacuation of the contents of the stomach after ingestion of sodium bicarbonate to neutralize the hydrochloric acid, or by soothing the hyperesthesia with atropin or hot water; also by the coincidence of the spasm with the acme of digestion, when the secretion of hydrochloric acid is at its height. The success of various remedies is probably due to their action on the gastric sensibility, and not on the secretions, as hitherto assumed. Lavage of the stomach with tepid alkaline water, hydrotherapy, climate, suggestion and electricity all act in the same way, curing the neuropathic hyperesthesia. It is possible that continuous gastric succorrhea might be due to a primary and fundamental disturbance in the secretion, but in Sansoni's experience he has found in every case in which the symptoms indicated continuous gastric succorrhea, remains of food in larger or smaller amounts in the fasting stomach, even in the morning.

October 6.

Varicellic Rashes. L. Cerf.—About the only positive differentiating symptom between a varicellic rash and scarlet fever is the pink stripe observed in the center of the white band that follows linear pressure with the nail or point of a pencil on a patch of the eruption in scarlet fever. Varicellic rash may occur anywhere on the body, but the eruption in variola usually first occurs as "bathing trunks." The scarlet-fever eruption always scales in time, while nothing of the kind occurs in a varicellic rash.

Gouty Angina Pectoris. L. Brodier.—The pathologic action of gout on the cardiac plexus is well illustrated in the case described, in which the attacks of angina pectoris from this cause alternated with joint troubles. No lesion of the aorta nor constriction of the coronary arteries was found at the autopsy, but the myocardium was altered and the right heart dilated.

Semaine Medicale (Paris), October 3.

The Pupil Danger Sign in Bromid Treatment of Epilepsy. Gilles de la Tourette.—The most successful, in fact the only treatment we have for essential epilepsy is with the bromids. They should be administered for two or three years with the most scrupulous vigilance in the exact doses ordered by the physician, using always the same spoon or medicine glass to ensure accuracy in the dose, which must be graduated to the individual case. A distinct advance in the treatment of epilepsy is the discovery of a sign which enables the exact individual dose to be determined for each patient. In the course of bromid treatment when the drug is well tolerated the pupils are normally dilated. They react as usual to light and accommodation. If the dose is increased, a moment arrives when the pupils become dilated and respond lethargically to light and accommodation. With a still larger dose the pupils are dilated to the maximum and do not react at all. When the reactions first become sluggish there is a general sensation of slight physical and mental depression. The patient feels heavier and tired, with less aptitude for mental and physical labor and with an inclination to sleep during the day. The appetite fails, with constipation in some cases. These symptoms in combination with the pupil sign indicate that the adequate individual dose has been reached. This condition is harmless and should be maintained, the dose of the bromids increased or diminished according as this condition varies. If the adequate dose is unmistakably attained at the end of two three-week periods—which represent a month and a half of treatment—it is seldom necessary to increase it more than 2 or 3 gm. during the remainder of treatment. Even in epileptics extremely sensitive to bromid intoxication it is possible to cautiously reach and keep up the adequate dose without general accidents of intoxication if the pupils are watched and the patient kept under surveillance. If exaggeration of the general symptoms and gastric disturbances occur, the bromid must be immediately suppressed and the patient purged and put on a strict milk diet with squills and digitalis to stimulate the heart and kidney action for three to four days. The bromid can then be recommenced in small doses until the adequate dose is reached once more. The seizures are liable to recur if the adequate dose of bromid is surpassed, the same as when too little is given. The local accidents are less easy to handle. They may coexist with the general, but are usually independent. They occur as cutaneous manifestations, chiefly in subjects predisposed to acne. A few slight patches of acne are trivial, but when a confluent eruption occurs it may interfere with the occupation and oppose an obstacle to efficient treatment. In case of absolute intolerance, the bromid can be administered by the rectum, using 1 or 2 gm. more than by the mouth. It is possible to determine the adequate dose by the pupil sign, the same as when bromid is taken by the mouth. In these cases it is sometimes possible to combine a small amount by the mouth with the rectal injection. The formula found most effective is a combination of 40 gm. of potassium bromid and 12 gm. each of sodium and ammonium bromid and sodium benzoate, in 1000 c.c. of boiled or distilled water. This is equivalent to 1 gm. of the combined bromids to a tablespoonful, which is taken after the first breakfast and on retiring. If the seizures are known to recur at certain hours, it is best to give two-thirds of the dose for the day just before the hour. The main features of the treatment described are the determination of the adequate dose and the maintenance of this dose until all accidents have disappeared, then saturating the system by maintaining the adequate dose at its maximum for a year longer, then gradually diminishing by a gram at each three-weeks' period under careful supervision, and resumption of the maximum adequate dose at any indication of trouble. The patient should be warned that if the proper dose is neglected and a seizure or vertigo occurs after six months, all the benefits of the course are lost and it will have to be commenced over again. Pregnancy is no contraindication to its continuance, nor a slight, transient, intercurrent affection. Charcot's method of administration is followed, increasing the dose by 1 gm. a week for three weeks and then diminishing at the same rate for three more, and then recommencing. In women the periods should range for four weeks, with the maximum corresponding to the menstrual period. The patient takes 3, 4 or 5 gm. of the bromids during three weeks and is then seen again or not until the end of the sixth week. The condition then gives an indication of the tolerance for the drug and suggests an increase or decrease of the maximum. Children frequently tolerate as much as an adult. In all cases the prompt determination of the adequate dose and its maintenance at this point, with treatment for two and one-half years, are the main points, commencing to diminish the dose about a year after the last symptoms.

Centralblatt f. Chirurgie (Leipsic), September 29 and October 6.

Indirect Sounding. Kuhn.—Four years have passed since Kuhn first described his sounds made of a spirally-wound wire, inside which a stiff sound is introduced. The spiral prevents injury while the stiff sound affords the desired information. Experience has confirmed the value of this combination, and he now relates instances in which a correct diagnosis had been impossible until this indirect sounding was resorted to. It has all the advantages of both a soft and a stiff sound, while its worm-like and rotating movements enable it to discover an excentrically located lumen. It is peculiarly adapted to the exploration of the biliary passages and fistulæ.

October 6.

Successful Disinfection of the Hands. J. Hahn.—While others have been laboring to evolve a method of thorough disinfection of the hands and proclaiming the failure of the usual methods, Hahn has been quietly following the technique which he described in the *Monatsschrift f. Geb. u. Gyn.*, v. 5, nearly four years ago. It attracted no notice at the time nor since, and yet it has proved unfailingly reliable in his experience, as a series of 136 operations without a single instance of even the slightest operative infection fully demonstrates. The hands and forearms are scrubbed four times in succession with soft soap and fresh water at 40 C. They are then washed for four minutes in 1 per thousand alcohol solution of sublimate and the forearms left wet. The hands are then rinsed in 1 to 2 per thousand aqueous solution of sublimate until all the alcohol is removed and dipped again into the sublimate-alcohol for a minute or two before and after the blouse is put on. Bacteriologic and other tests indicate that this method combines all that can be expected from disinfection of the hands.

Dermatologisches Centralblatt (Berlin), September.

Iodin Parotitis. K. Groen.—A young man under treatment for syphilis at various intervals took potassium iodid at least sixteen times. Eight times he reacted with an acute swelling of the parotid gland. Quinin had no effect in preventing the parotitis, but potassium bromid administered with the iodid on one occasion possibly co-operated in preventing the glandular lesion.

Dermatologische Zeitschrift (Berlin), September.

Urethral Pouch in Boys. J. V. Bokay.—The fourteen cases of true urethral diverticula that have been observed in boys impress the benefits of prompt surgical intervention in these cases. In six the operation resulted in a complete cure, and in two others a small fistula persisted. In the three personal cases described by Bokay the diverticulum was accompanied by severe bladder and kidney affections, and all terminated fatally. One was 2 weeks, the other 3 years old. The pouch had been noted in infancy in six cases. In only 3 out of the 14 was there a perceptible valve-formation or stricture to which the development of the diverticulum could be ascribed. Consequently Bokay is inclined to attribute all the cases to congenital malformation, although it may not have caused disturbance, nor even attracted the patient's attention for years. The treatment consisted in slitting the urethra and cutting an ellipse out of the pouch, suturing en masse or in tiers, or packing the cavity with gauze and allowing the wound to heal by granulation. He also describes a single case of a false pouch due to a calculus.

Lupus Extirpation. E. Lang.—In this review of the 85 cases of lupus operated on by Lang, in only 58 could the results be followed to date after an interval of more than six months. Of these 39 have had no relapse during the six months to seven years since the operation: 19 have had slight tion. A bacillus is also constantly found resembling the pseudo-diphtheria micro-organism. In times of epidemic diphtheria tonsillotomy should be postponed.

October 4.

Movement Phenomenon in Mouth and Throat Sign of Insufficiency of the Aortic Valves. H. Schlesinger.—The sign described consists in the pulsation and rhythmic movement or displacements observed in the portions of the mouth and throat most exposed to the influence of the aortic pulsation, especially the tonsils and root of the tongue.

Gazzetta Degli Ospedali (Milan), September 16, 23 and 30.

Cutaneous Oxyuriasis. P. Barbagallo.—The invasion of the skin around the anus by the oxyuris has been reported three times. The writer adds a fourth case in which the parasites colonized all over the region, favored by the scratching of the patient to relieve the pruritus caused by the worms.

Pyloroplasty. G. B. Segale.—To obviate some of the defects of gastroenterostomy while securing its advantages, Segale proposes an operation in case of stenosis of the pylorus which consists in a curved incision extending longitudinally above and below the constriction. The two lips of the incision are then pulled in opposite directions and the constriction twisted at the same time. The wound is then sutured in this position. The operation has been done twice on man and with eminently satisfactory results in each case.

Large Malarial Spleen Reduced With Iodin. V. Piga.—A syringeful of one part iodin to two parts potassium iodid in 100 parts water was injected hypodermically in the left hypochondrium in a severe case of malarial infection and much enlarged spleen. Ten injections were made in all and the spleen gradually returned to normal.

September 23.

Success of Salophen in Sciatica. A. Ghetti.—Two rebellious cases of sciatica in women 37 and 50 years of age were relieved of pain with six hypodermic injections of salophen in alkalinized water. Thirty injections induced a permanent cure.

Treatment of Cutaneous Tuberculosis With Guaiacol. G. B. Burzhagi.—The surface of the cutaneous tuberculous lesion in the case described was painted with a mixture of guaiacol and olive-oil, each 40 gm. in 10 gm. of 60 per cent. alcohol. The ulcerations were located on the leg and were first evacuated and scraped. Cicatrization was complete in twenty-eight days of the guaiacol treatment.

Best Method of Using Gelatin for Hemorrhage. F. S. Rocchi.—Experimental tests with gelatin testify that the most effective means of administering gelatin to arrest hemorrhage is by the rectum, injecting 50 gm. of a hot 2 per cent. solution. Its action is manifest in five to ten minutes and lasts for six hours. This method obviates dilatation of the cervix in hemorrhagic endometritis and menorrhagia while it is fully as effective as direct local applications.

September 30.

Pneumococcus Conjunctivitis. G. Consalvo.—An epidemic of conjunctivitis was observed by the writer and the pneumococcus found constantly in the secretions. It is a contagious affection, attacking persons of all ages. The acute attack terminates in about ten days. It has a tendency to become chronic, but remains benign and rarely compromises the integrity of the eye.

Grece Medicale (Syra), September.

Resection of the Vagi in Dogs. R. Nicolaides.—A portion of the cervical pneumogastric nerve, 5 cm. long, was resected in three dogs, first on one side and, forty-seven to fifty-seven days later, on the other. Simultaneous bilateral resection kills the animals, but with this interval the disturbances were comparatively slight and the dogs were eating with good appetite in five days, and are still alive, several months later. The number of respirations gradually diminished the day after each operation, but soon returned to the previous condition.

St. Petersburger Medicinische Wochenschrift, September 22.

Operative Treatment of Extroversion of Bladder. E. Graubner.—Extremely satisfactory results were obtained by a Maydl operation on a girl of 16 who suffered from congenital extroversion of the bladder and total incontinence. The ureters were implanted in the sigmoid flexure. Continence is complete; the patient is robust and nothing during the eighteen months since the operation indicates a tendency to ascending pyelonephritis or paralysis of the sphincter ani.

Books and Pamphlets.

Acknowledgement of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review as dictated by their merits, or in the interest of our readers.

A Dictionary of Medical Science.—Containing a Full Explanation of the Various Subjects and Terms of Anatomy, Physiology, Medical Chemistry, Pharmacy, Pharmacology, Therapeutics, Medicine, Hygiene, Dietetics, Pathology, Bacteriology, Surgery, Ophthalmology, Otology, Laryngology, Dermatology, Gynecology, Obstetrics, Pediatrics, Medical Jurisprudence, Dentistry, Veterinary Science, etc. By Robley Dunglison, M.D., LL.D., Late Professor of Institutes of Medicine and Medical Jurisprudence in the Jefferson Medical College of Philadelphia. Twenty-second Edition, with Appendix, Thoroughly Revised and Greatly Enlarged, and with the Pronunciation, Accentuation, and Derivations of the Terms, by Richard J. Dunglison, A.M., M.D. Cloth. Pp. 1376. Price, $7.00. Philadelphia and New York: Lea Brothers & Co. 1900.

An American Text-Book of Physiology. By Henry P. Bowditch, M.D.; John G. Curtis, M.D.; Henry H. Donaldson, Ph.D.; W. H. Howell, Ph.D., M.D.; Frederic S. Lee, Ph.D.; Warren P. Lombard, M.D.; Graham Lusk, Ph.D., F. R. S., (Edin.); W. T. Porter, M.D.; Edward T. Reichert, M.D.; Henry Sewall, Ph.D., M.D. Edited by William H. Howell, Ph. D., M.D., Professor of Physiology in the Johns Hopkins University, Baltimore, Md. Second Edition, Revised. Vol. I. Blood, Lymph, and Circulation; Secretion, Digestion, and Nutrition; Respiration and Animal Heat; Chemistry of the Body. Cloth. Pp. 598. Price, $3.00. Philadelphia: W. B. Saunders & Co. 1900.

A Manual of Syphilis and the Venereal Diseases. By James Nevins Hyde, A.M., M.D., Professor of Skin, Genito-Urinary, and Venereal Diseases, Rush Medical College, Chicago, and Frank Hugh Montgomery, M.D., Associate Professor of Skin, Genito-Urinary, and Venereal Diseases, Rush Medical College, Chicago. Second Edition, Revised and Enlarged. With 58 Illustrations in the Text, and 19 full-page Lithographic Plates. Cloth. Pp. 594. Price, $4.00. Philadelphia: W. B. Saunders & Co. 1900.

A Book of Detachable Diet Lists. For Albuminuria, Anemia, and Debility. Constipation, Diabetes, Diarrhea, Dyspepsia, Fevers, Gout or Uric Acid Diathesis. Obesity, Tuberculosis, and a Sick-Room Dietary; Compiled by Jerome B. Thomas, Jr., A.B., M.D.; Instructor in Materia Medica, Long Island College Hospital. Second Edition, Revised. Cloth. Price, $1.25. Philadelphia: W. B. Saunders. 1900.

Twentieth Century Practice. An International Encyclopedia of Modern Medical Science by Leading Authorities of Europe and America. Edited by Thomas L. Stedman, M. D., New York City. In Twenty Volumes. Volume XX. Tuberculosis, Yellow Fever, and Miscellaneous, General Index. Cloth, Pp. 906. Price, $5.00. New York: William Wood & Co. 1900.

Rhinology, Laryngology and Otology and Their Significance in General Medicine. By E. P. Friedrich, M. D., Privatdocent at the University of Leipzig. Authorized Translation from the German. Edited by H. Holbrook Curtis, M. D., Consulting Surgeon to the New York Nose and Throat Hospital. Cloth. Pp. 348. Price, $2.50. Philadelphia and London: W. B. Saunders & Co. 1900.

Practical Manual of Diseases of Women and Uterine Therapeutics for Students and Practitioners. By H. Macnaughton-Jones, M.D., M.Ch., Master of Obstetrics (Honoris Causa), Royal University of Ireland. Eighth Edition, Revised and Enlarged with 640 Illustrations and 28 Plates. Cloth. Pp. 935. Price, $5.00. New York: William Wood & Co. 1900.

Text-Book Upon the Pathologic Bacteria for Students of Medicine and Physicians. By Joseph McFarland, M.D., Professor of Pathology in the Medico-Chirurgical College, Philadelphia. With 142 Illustrations. Third Edition, Revised and Enlarged. Cloth. Pp. 621. Price, $3.25. Philadelphia: W. B. Saunders & Co. 1900.

Heart Diseases in Childhood and Youth. By Charles W. Chapman, M.D., Durh., M.R.C.P., Lond., Physician to the National Hospital for Diseases of the Heart. With an Introduction by Sir Samuel Wilks, Bart., M.D., F.R.S., Physician Extraordinary to H. M. the Queen. Cloth. Pp. 98. Price, 3s. 6d. London: The Med. Publishing Co., Ltd.

A Text-Book of the Diseases of Women. By Henry J. Garrigues, A.M., M.D., Gynecologist to St. Mark's Hospital in New York City. With 367 Illustrations. Third Edition, Thoroughly Revised. Cloth. Pp. 756. Price, $4.50. Philadelphia: W. B. Saunders & Co. 1900.

Bacteriology and Surgical Technique for Nurses. By Emily M. A. Stoney, Superintendent of the Training School for Nurses, St. Anthony's Hospital, Rock Island, Ill. Illustrated. Cloth. Pp. 190. Price, $1.25: W. B. Saunders & Co. 1900.

A Short Practice of Gynecology. By Henry Jellett, B.A., M.D., B.Ch., B.A.O. (Dublin University), F.R.C.P.I., L.M., Late Assistant Master, Rotunda Hospital. With 125 Illustrations. Cloth. Pp. 436. Price, $2.63. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co.

The Attainment of Womanly Beauty of Form and Features. The Cultivation of Personal Beauty Based on Hygiene and Health Culture by Twenty Physicians and Specialists. Edited by Albert Turner. Cloth. Pp. 256. Price, $1.00. New York: Health-Culture Co.

Ulceration of the Bladder: Simple, Tuberculous, and Malignant. By E. Hurry Fenwick, F. R. C. S., Surgeon of the London Hospital. Cloth. Pp. 85. Price, $1.75. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co.

Hernia: Its Etiology, Symptoms and Treatment. By W. McAdam Eccles, M. S. (Lond.), F.R.C.S. (Eng.), Assistant Surgeon West London Hospital. Cloth. Pp. 231. Price, $2.50. New York: Wm. Wood & Co. 1900.

Transactions of the Colorado State Medical Society. Thirtieth Annual Convention. By-laws and List of Members. Cloth. Pp. 446. Denver: Published for the Society.

PAMPHLETS.

A Simple Operation for Divergent Strabismus. Change of Refraction from Compound Hypermetropic Astigmatism to Compound Myopic Astigmatism—Glaucoma. Implantation of a Glass Ball Into the Orbital Cavity. Iritis: Its Treatment. Strabismus: Mules' Operation. Epiphora; Lachrymal Abscess; Congenital Absence of Lachrymal Punctae; Stricture of the Lachrymal Duct. By L. Webster Fox, A.M., M.D., Philadelphia. Reprints.

A Case of Traumatic Varix of the Orbit in Which Ligation of the Left Common Carotid Artery Was Successfully Performed. A Clinical and Histologic Study of a Case of Melanotic Sarcoma of the Choroid Presenting Symptoms of Secondary Glaucoma. Clinical Study of the Ocular Symptoms Found in So-called Posterior Spinal Sclerosis. Gumma of the Iris and Ciliary Body. Recovery With Normal Vision. Recovery of Vision by an Iridectomy; With Removal of Lens-Debris in a Case of Blindness of More Than Thirteen Years' Duration. By Charles A. Oliver, A.M., M.D., Philadelphia. Reprints.

Cataphoresis in Trachoma. Report of a Case of Double Mastoiditis—Operation—Recovery. By Geo. F. Keiper, M.D., Lafayette, Ind. Reprints.

Compound Fractures. Excision of High Rectal Carcinoma Without Sacral Resection. By N. Senn, Ph.D., LL.D., Chicago. Reprints.

Malformation of the Uterus. By Frank T. Andrews, M.D., Chicago. Reprinted from Amer. Gyn. and Obs. Jour.

Myotherapy. By Nathan Herman, M.D., Baltimore, Md. Reprinted from Md. Med. Jour.

Studies in Pancreatic Digestion. Made with Pancreatic Juice. By B. K. Rachford, M.D., Professor of Therapeutics, Medical College of Ohio. Paper. Pp. 99. Cincinnati, Ohio: Cincinnati Lancet Press. 1900.

Special Classes for Mentally Defective School Children. By Walter Channing, M.D. Reprinted from Charities Review.

Successful Treatment of Variola and Improved Method of Vaccination-Vaccinoid. By V. Lehmann, M.D., Hahnville P. O., La. Reprinted from N. O. Med. and Surg. Jour.

Summarized Report of Fourteen Years' Work in Abdominal Surgery. By F. F. Lawrence, M.D., D.Sc., Columbus, Ohio. Paper. Pp. 11.

The Comparative Value of Enucleation and the Operations Which Have Been Substituted for It. By G. E. de Schweinitz, A.M., M.D., Philadelphia. Paper. Pp. 44.

Transactions of the Florida Medical Association for the Year 1900. Held at Orlando, Fla., April 11 and 12. Paper. Pp. 113. Jacksonville. Fla.: East Florida Printing Co. 1900.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advan

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have th contributions typewritten before submitting them for publicati The expense is small to the author—the satisfaction is great the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.
